ambiguity, the most inclusive way to rephrase this is probably the latter alternative, to change the requirement to, "…that use measurements of electrical quantities to determine anomalies…" Finally, Footnotes 2 and 3 (in Requirement 4) are identical. Unless that's intentional, one should be removed. (And note that Footnote 2 is missing a period.)

Suggest adding “Protection System Components including” in the beginning. This is because the word “components” has been used extensively throughout the standard and there is no mention of what constitutes a protection system component in the standard. The word “component” does find mention in FAQs, however, it is recommended to mention it in the body of the standard. The revised definition should read as follows: Protection System Components including Protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers or other interrupting devices. An alternative definition for Protection System to eliminate the need to capitalize “component”: The collective components comprised of protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers or other interrupting devices. There is not enough clarity on whether a Distribution Provider (DP) will be able to clearly identify which protection system components it does own and needs to maintain. Many DPs own and/or operate equipment identified in the existing or proposed definition. However, not all such equipment translates into a transmission Protection System. The definition needs clarification on when such equipment is a part of the transmission protection system. This is critical since NPCC had proposed a SAR to this effect which was not accepted by NERC citing that this concern will be incorporated in the revised standard. Also, reference should be made to Project 2009-17 in which Y-W Electric Association, Inc. (Y-WEA) and Tri-State Generation and Transmission Association, Inc. (Tri-State) requested an interpretation of the term "transmission Protection System" and specifically whether protection for a radially-connected transformer protection system energized from the BES is considered a transmission Protection System and is subject to these standards.
No
The time provided for the first phase “at least six months” is too open ended and does not give entities a clear timeline. Suggest 1 year for the first phase. Suggest phasing out the second phase in stages.

We agree that the definition provides clarity and will enhance the reliability of the Protection Systems to which it is applicable; however, we believe there should be a direct linkage of the definition's effective date to the approval and implementation schedule of PRC-005-2. Since this new definition is directly linked to the proposed revised standard, it would be premature to make this definition effective prior to the effective date of the new standard.
No
As noted above, the implementation plan should be linked to the approval of PRC-005-2. Since this new definition is directly linked to the proposed revised standard, it would be premature to make this definition effective prior to the effective date of the new standard.

While the drafting team has done a great job of simplifying the implementation plan from the original draft 1 language, the current language has some ambiguities. I do not understand what the term "the end of the first calendar quarter six months following regulatory approvals" means. What is wrong with just saying "within nine months (or six months or twelve months) following regulatory approvals? Using the current language I would be inclined to assume it is six months so I can avoid a dispute (and quite possibly a notice of alleged violation) over a date. Also, I am not sure what the term "the end of the first complete maintenance and testing cycle described in the entity's program description" means. It is quite likely that a registered entity will make the required definition change to its maintenance program (at approximately six months) and wind up with devices that need to be tested. Is the implementation plan attempting to provide some allowed time delay so the registered entity will not be out of compliance even though it has devices that are now beyond the maximum testing interval due to the definition change? The existing language implies that within approximately six months of regulatory approval, the maintenance program needs to be changed to incorporate the revised definition for Protection System. However, the effective date for the revised maintenance program is going to be some date that corresponds with the end of the first complete maintenance and testing cycle in that program. I really don't understand what that time period is and I believe the drafting team needs to put in something that clears up this confusion. By testing cycle do you mean "maximum interval" as shown in the PRC-005 table? Do you mean the "maximum interval" that a registered entity includes in their maintenance program? If so, do you intend the implementation to be a different date for protection devices depending on the maximum testing interval? Or do you envision some date beyond the six months where the entire maintenance program (with the definition change) becomes effective and any registered entities with out-of-compliance issues would need to file mitigation plans?

It is still unclear whether relays that respond to mechanical inputs, such as sudden pressure relays, are included in the proposed definition as protective relays. While PRC-005-2 R1 limits the scope of that particular standard to protection systems that sense electrical quantities, it is remains unclear in other standards that use the defined term whether mechanical input protections are included. We suggest that “Protective Relay” also be defined, and that the definition clearly exclude devices that respond to mechanical inputs in line with the NERC interpretation of PRC-005-1 in response to the CMPWG request.

We agree that the definition provides clarity and will enhance the reliability of the Protection Systems to which it is applicable. However, we feel that there needs to be a direct linkage of the definition’s effective date to the approval and implementation schedule of PRC-005-2. Since this new definition is directly linked to the proposed revised standard, it would be premature to make this definition effective prior to the effective date of the new standard.
No
The revised definition should not be made effective until the revised PRC-005-2 is in effect. There is no definite reliability benefit to balloting this definition prior to the revised standard. If balloted and approved, entities would definitely have to modify their Protection System Maintenance and Testing Program methodology, but there is no obligation to or guarantee of any additional maintenance being performed. PRC-005-2 includes this definition, the maintenance activities, and the intervals that will ensure execution of the maintenance and testing.

1) We note that the definition of a "Protection System" has been expanded to include the trip coils and what used to be confined to batteries has now been expanded to "station DC supply." "Trip coils" is an improvement. Inasmuch as the mark-up changing "DC" to "dc" is intended to communicate a more general term as opposed to a strict definition, it leaves room for differing opinions among auditors as to what all should be included. We support the change to exclude battery chargers since the rationale for their inclusion was never clear. The battery itself will be, without exception, the "first responder" to provide DC power to a Protection System. However, battery chargers have not been excluded under the FAQs. 2) The SPCTF's effort to define applicability in terms of "Facilities" is confusing. Additionally, it is unclear how the terms "component," "element" and "Facility" are intended to relate to one another. An assumption may be that one or more components (which are physical assets) can comprise an "element," one or more of which can be associated with an identifiable function, aligning with the five Protection System Equipment Categories, found in SPCTF's "PROTECTION SYSTEM MAINTENANCE—A Technical Reference, dated Sept. 13, 2007, and that "Facility" is as used in 4.2.1 of the Standard Development Roadmap, dated May 27, 2010. Please provide guidance on the terms relate to one another. 3) The structure of the proposed standard is less clear than the existing standard PRC-005-1 because of the potential for ambiguity between the definition of Protection System and how the term "Facilities" is applied. A suggested resolution would be to revise the definition of Protection System to resolve this ambiguity or to delete reference to 86 lockouts and auxiliary relays in the description of "Facilities." If the 86 lockout relays are to be included, they should be added as part of the DC Control Circuitry "element" (as found in the NERC Glossary) of the circuit that energizes the 86 relay, thus placing it within the definition of a "Protection System."—once —and therefore in a manner that would require only one scheduled maintenance to be performed if the testing schemes are properly set up. We do agree, however, that sudden pressure relays, reclosing relays, and other non fault detecting relays such as loss of cooling relays should not be referenced as part of the "dc control circuitry" Element.

The application of this definition to Reliability Standards NUC-001-2, PER-005-1, PRC-001-1, and PRC-004-1 results in confusion as to whether relays with mechanical inputs are included or excluded from this definition. PRC-005-2_R1 contains language limiting its applicability to relays operating on electrical inputs only, but the remaining standards that rely on this definition are not so specific. This being the case, it would make much more sense to clearly define what devices are actually meant in the glossary definition rather than leaving it up to each individual standard to do so.
Yes
Individual
Armin Klusman
CenterPoint Energy
No
CenterPoint Energy believes the proposed definition of "Protection System" is technically incorrect. The present definition does not include trip coils of interrupting devices, such as circuit breakers; and correctly so, as trip coils are components of the interrupting device. A Protection System has correctly performed its function if it provides tripping voltage up to the circuit breaker trip coil. From that point, the circuit breaker can fail to timely interrupt fault current due to several factors, such as a binding mechanism that affects breaker clearing time, a broken pull rod, a bad insulating medium, or bad trip coils. Local breaker failure protection, or remote backup protection, is installed to address the various possible causes of circuit breaker failure. For correctness, the definition of "Protection System" should be "Protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from

the station dc supply UP TO THE TERMINALS OF the trip coil(s) of the circuit breakers or other interrupting devices."

ATC does not agree to the implementation plan proposed. While it makes common sense to proceed with R1 prior to proceeding with implementing R2, R3, and R4, the timeline to be compliant for R1 is too short. It will take a considerable amount of resources to migrate the maintenance plan from today's standard to the new standard in phase one. ATC recommends that time to develop and update the revised program be increased to at least one year followed by a transition time for the entity to collect all the necessary field data for the protection system within its first full cycle of testing. (In ATC's case would be 6 years) To address phase two, ATC believes human and technological resources will be overburdened to implement this revised standard as written. The transition to implementing the new program will take another full testing cycle once the program has been updated. Increased documentation and obtaining additional resources to accomplish this will be challenging. Implementation of PRC-005-2 will impact ATC in the following manner: a. Increase costs: double existing maintenance costs. b. Since there will be a doubling of human interaction (or more), it is expected that failures due to human error will increase, possibly proportionately. c. Breaker maintenance may need to be aligned with protection scheme testing, which will always contain elements that are include in the non-monitored table for 6 yr testing. d. ATC is developing standards for redundant bus and transformer protection schemes. This would allow ATC to test the protection packages without taking the equipment out of service. Further if one system fails, there is full redundancy available. With the current version of PRC-005-2, ATC would need to take an outage to test the protection schemes for a transformer or a bus, there is not an incentive to install redundant schemes. ATC is working with a condition based breaker maintenance program. This program's value would be greatly diminished under PRC-005-2 as currently written. Consideration also needs to be given for other NERC standards expected to be passed and in the implementation stage at the same time, such as the CIP standards.

We recommend modifying the language to remove circuit breakers altogether: "…through the trip coil(s) of the circuit breakers or other interrupting devices."
No
The implementation plans for both the definition and standard are confusing. Does this imply a "clean slate" approach can be used? i.e. do entities have up to the first interval window to complete the maintenanceor must they have it complete on day 1 of the standard and again by the first interval? It also appears that the implmentation plans are conflicting whereby one requires full compliance and the other allows 6 months...the definition implmeentation plan also refer to a basis document though the standard does not require one.

The definition is ready for ballot with the addition of auxiliary relays to the definition of protective relays. There is a potential for an entity to determine that auxiliary relays do not perform a protection function since they typically do not sense fault current. Furthermore, one could determine that the term "circuitry" only refers to the wiring to connect the various DC devices together. We suggest adding "auxiliary relays necessary for correct operation of protective devices" to improve clarity of the definition. With regard to the change from the current definition phrase "station batteries" to the new definitions phrase "station DC supply", it may not be clear to the reader that this includes battery chargers. To alleviate future interpretation issues, we suggest adding a clarifying statement at the end of the definition, such as "The station DC supply includes the battery, battery charger, and other DC components". The acronym "dc" should be capitalized.

1. It is unclear whether “voltage and current sensing inputs” include the instrument transformer itself, or does it pertain to only the circuitry and input to the protective relays? 2. It is not clear what is included in the component, “station dc supply” without referring to other documents (the posted Supplementary Reference and/or FAQ) for clarification. The definition should be sufficiently detailed to be clear. 3. If Protection Systems trip via AC methods, are those systems, and the associated control circuitry included?
No
For entities that may not have included all elements reflected in the modified definition within their PRC-005-1 program, 6-months following regulatory approvals may not be sufficient to identify all relevant additional components, develop maintenance procedures, develop maintenance and testing intervals, develop a defendable technical basis for both the procedures and intervals, and train personnel on the newly implemented items. We propose that a 12-month schedule following regulatory approvals may be more practical.

Because the definition changes the scope of what a protection system covers, increasing that scope, the definition should not be balloted separately from PRC-005-2 so that the industry knows what is being committed to. For instance, the circuitry connecting the voltage and current sensing devices to the relays is a scope expansion. station DC supply increases the scope to include the charger, etc. This scope increase needs to have an appropriate implementation period.
No
As stated in response to Question 1, it is inappropriate to change the definition o Protection System for PRC-005-1 and the new definition should wait for the new standard. In all honesty, the new PRC-005-2 lays out the program anyway, so, any change to the definition needs to be accompanied by a the commitment associated with that change.
Individual
Greg Rowland
Duke Energy
No
It is unclear whether the revised definition includes PTs and CTs, but it does include the wiring. We don't see a way to list the wiring in R1.1 and provide supporting compliance evidence. We believe the phrase "and associated circuitry from the voltage and current sensing devices" should be struck from the definition.
No
Definition should be implemented concurrently with PRC-005-2.

Based on review of ballot pool comments there are still too many questions that should be resolved prior to submittal for ballot. It is suggested that a specific reference to the supplementary reference document figures 1 & 2 and the legend be added. That would further define the protection system components and scope boundary.
No
- The draft implementation plan general considerations have a requirement to identify all the protection system components addressed under PRC-005-1 and PRC-005-2 for potential audits while modifying the existing programs. The standard revision will require extensive reviews and possibly add significant amounts of components to the program. This is listed as a requirement without a specific deadline other than supplying the information as part of an audit. If an audit is scheduled or announced early in the implementation period the evidence is required. The requirement for identifying all the components in the implementation process should have a time specified with bases for the starting point. - Where additional definition of a protection system scope boundary is determined as a result of the standard revisions, the implementation plan completion requirement should be at the end of next maintenance interval of that added protection system component. There may be situations where additional scope as determined by the additions or revisions to the standard and/or supporting reference material (e.g., an auxiliary contact input in a tripping scheme) would require going back and taking equipment out of service to perform that one check. To keep the maintenance and outage schedules coordinated the new requirements should be at the end of current cycles, not beginning.

The term "station" should either be defined or removed from the definition, as it implies transmission and distribution assets while the term "plant" is used to define generation assets. It would suffice to simply refer to the "DC Supply".
No
As written, the implementation plan only specifies a time frame for entities to update their documentation for PRC-005-1 and PRC-005-2 compliance. The implementation plan also needs to give entities a time frame to address any required changes to their documentation for other standards that use the term "Protection System", including but not limited to NUC-001-2, PER-005-1, PRC-001-1, etc.
Individual
Rex Roehl
Indeck Energy Services
No
It presumes that all relays in a plant are Protective Systems that affect BES reliability. As discussed at the FERC Technical Conference on Standards Development, the goal of the standards program is to avoid or prevent cascading outages--specifically not loss of load. The purpose of PRC-005-2 uses the term in its global sense but there is no subset of the Protection Systems that affect reliability. PRC-005 R1 requires identification of all components. With the broad definition proposed, and no separate term for only relays and other components that have been identified as affecting reliability, confusion results. If this term has its global meaning, then another term, such as Reliability Protection Systems, should be instituted to avoid confusion.
No
The definition should not be implemented separate from PRC-002-2. The PRC-002-2 implementation plan would be adequate.
Individual

Hydro One suggests adding “Protection System Components including” in the beginning. This is because the word “components” has been used extensively throughout the standard and there is no mention of what constitutes a protection system component in the standard. The word

“component” does find mention in FAQs, however, it is recommended to mention it in the main standard. The revised definition should read as follows: Protective System Components including Protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers or other interrupting devices. There is not enough clarity on whether a Distribution Provider (DP) will be able to clearly identify which all protection system components does it own and need to maintain. This is critical since NPCC had proposed a SAR to this effect which was not accepted by NERC citing that this concern will be incorporated in the revised standard. Also, reference should be made to Project 2009-17 in which Y-W Electric Association, Inc. (Y-WEA) and Tri-State Generation and Transmission Association, Inc. (Tri-State) requested an interpretation of the term "transmission Protection System" and specifically whether protection for a radially-connected transformer protection system energized from the BES is considered a transmission Protection System and is subject to these standards.
No
The time provided for the first phase “at least six months” is too open ended and does not give entities a clear timeline. HYDRO ONE suggests 1 year for the first phase. Also, HYDRO ONE suggests phasing out the second phase in stages.
Individual
Kirit Shah
Ameren
Yes
We agree that the definition provides clarity and will enhance the reliability of the Protection Systems to which it is applicable; however, we suggest that a Glossary term for Protective Relay be added in order to clarify in all standards inclusion of relays that measure voltage, current, frequency and/or phase angle to determine anomalies, as stated in PRC-005-2 R1. We believe there should be a direct linkage of the definition’s effective date to the approval and implementation schedule of PRC-005-2. Since this new definition is directly linked to the proposed revised standard, it would be premature to make this definition effective prior to the effective date of the new standard. We agree that the voltage and current inputs at the protective relays correctly identifies that component, that this excludes the instrument transformer itself. We suggest replacing "to" with "at", and omitting "and associated circuitry from the voltage and current sensing devices."
No
As noted above, the implementation plan should be linked to the approval of PRC-005-2. Since this new definition is directly linked to the proposed revised standard, it would be premature to make this definition effective prior to the effective date of the new standard. Otherwise, entities must address equipment, documentation, work management process, and employee training changes needed for compliance twice within an unreasonably short timeframe. If PRC-005-2 receives regulatory approval in 1st quarter 2011, PSMP implementation along with this revised definition should be effective at the beginning of 2012 to coincide with the calendar year. These nine months will be needed to fully assess and address the necessary maintenance program documentation changes, maintenance system tool revisions, and personnel training needed to incorporate this new definition into our program.

No
The second part of the implementation effective date does not make sense and might be wrong. The second part talks about implementing any addtional maintenance and testing (required in R2 of PRC-005-1- Transmission and Generation Protection system Maitenance and Testing); this is refering to version 1 of the standard and there should be no additional maintenance and testing added from version 1 of the standard, just version 2 which is the new version. Overall, the wording on this implementation plan needs to be made more clear about how the implementation plan will work.

NERC Staff
Mallory Huggins
NERC
Yes
Still, to make sure the reference to dc supply is more generic than just “station dc supply,” NERC staff suggests the following modified definition of Protection System: "Protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices, and any dc supply or control circuitry associated with the preceding devices."
Yes
Individual
Terry Habour
MidAmerican Energy Company
No
The definition is expanded and clarified in the language of PRC-005-2. These changes should be incorporated in the definition to insure it is used consistently in PRC-005 and any other standards where it appears. The following is a suggested revised definition: “Protection System” is defined as: A system that uses measurements of voltage, current, frequency and/or phase angle to determine anomalies and to trip a portion of the BES to provide protection for the BES and consists of 1) Protective relays for BES elements and, 2) Communications systems necessary for correct BES protection system operations and, 3) Current and voltage sensing devices supplying BES protective relay input and, 4) Station DC supply to BES protection systems excluding battery chargers, and 5) DC control trip paths to the trip coil(s) of the circuit breakers or other interrupting devices for BES elements.
No
The protection system definition implementation plan should be consistent with the implementation plan of PRC-005-2 R1. Actual maintenance requirements implementation should be as required by the PRC-005-2 implementation plan and should not be included in the implementation plan for the protection system definition.

The Time Horizons are too narrow for the implementation of the standard as written. The SDT appears to have not accounted for the data analysis associated with performance based systems. The data collection, analysis, and subsequent decisions associated development of a maintenance program and its justification do not occur overnight especially with larger utilities. In addition, this new standard will require complete rewrite of an entities internal maintenance programs. The internal processes associated with these vary based on the size of the entity and its organizational structure. Since this standard is so invasive into the internal decisions

concerning maintenance, the standard should allow at least 18 months for entities to rewrite their internal maintenance programs to meet the program development requirements and 18 months to train the staff in the new program, incorporate the program into the entities compliance processes, and to implement the new program.

Consideration of Comments on Initial Ballot of PRC-005-2 – Protection System Maintenance

The Protection System Maintenance Standard Drafting Team (PSM SDT) thanks all those who participated in the initial ballot for the proposed revisions to PRC-005 - Protection System Maintenance.

- 87.85% quorum
- 39.35 % weighted segment approval

All comments received with affirmative and negative ballots are included in this report.

All balloters are advised to review the comments and responses in this report as an aid in determining how to participate in the recirculation ballot.

Both a clean and a redline version of the standard that shows the conforming revisions are posted at the following site:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Many commenters objected to the establishment of maximum allowable intervals and offered comments on virtually every individual activity and interval within the Tables. The SDT responded that "FERC Order 693 and the approved SAR assigned the SDT to develop a Standard with maximum allowable intervals and minimum maintenance activities." In an effort to provide more clarity, the SDT also completely revised the Tables of maximum maintenance intervals/minimum maintenance activities, and made numerous other changes throughout the draft Standard. Many commenters also indicated a preference for much of the information that is currently contained within the reference documents to be included within the Standard itself. The SDT responded by including the definitions of terms exclusively used within this standard, specifically "component type", "component", "segment", "maintenance correctable issue", and "countable event", , within the body of the standard. Numerous comments were also offered, proposing that the VSLs allow for some amount of non-compliance with the Standard before incurring a violation. The SDT responded by stating that: "The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation."

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herbert Schrayshuen, at 609-452-8060 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

Comment:	While voting affirmative due to the improvements over the existing standards, we do have the following comments. We hope the Standards Team can take these comments and suggested improvements into account although we did not get our comments in during the official comment period due to confusion over the overlapping comment/ballot period. The following are ITC Holdings comments corresponding the questions on the comment form: Regarding Question #1: ITC Holdings does not agree with the 6 year time interval for functional testing of the control and trip circuits. It has been our experience that trip failures are rare and that our present 10 year control, trip tests, and other related testing are sufficient in verifying the integrity of the scheme. A scheme that is 100% microprocessor relays except for 1 electromechanical AR or SG relay would be forced to a 6 year interval instead of a 12 year interval. This seems unreasonable for schemes that are otherwise identical. Comments on Question #4: ITC Holdings agrees with the measure and data retention requirements assuming that the requirements only apply to test data after the effective date of the approved standard. Comments on Question #7: It should clearly state in the definition or elsewhere in the standard that automatic ground switches intended to protect the BES are to be considered interrupting devices. This is stated in the Supplemental Reference but the Supplemental Reference is not part of the standard. Please consider splitting the first row in Table 1a (Protective Relays) into 2 separate rows, one for relays other than microprocessor and the other for microprocessor relays. • Include the sentence “Verify that settings are as specified.” In both rows to be clear that this applies to both categories. (The following is intended to be helpful information only not to be included in the comments) The following provides a clue as to what Time Horizon means: From: http://www.nerc.com/docs/pc/ris/Order_890-A_pro_forma_Attachment_C.doc (1) A detailed description of the specific mathematical algorithm used to calculate firm and non-firm ATC (and AFC, if applicable) for its

	scheduling horizon (same day and real-time), operating horizon (day ahead and pre-schedule) and planning horizon (beyond the operating horizon); See Definition at: http://www.nerc.com/files/Time_Horizons.pdf Copy below: Time Horizons Time Horizons are used as a factor in determining the size of a sanction. If an entity violates a requirement and there is no time to mitigate the violation because the requirement takes place in real-time, then the sanction associated with the violation is higher than it would be for violation of a requirement that could be mitigated over a longer period of time. When establishing a time horizon for each requirement, the following criteria should be used: 1. Long-term Planning — a planning horizon of one year or longer. 2. Operations Planning — operating and resource plans from day-ahead up to and including seasonal. 3. Same-day Operations — routine actions required within the timeframe of a day, but not real-time. 4. Real-time Operations — actions required within one hour or less to preserve the reliability of the bulk electric system. 5. Operations Assessment — follow-up evaluations and reporting of real time operations.
Response:	Thank you for your comment. Question #1 - The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. The SDT believes that mechanical solenoid-operated devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-based maintenance is an option to increase the intervals if the performance of these devices supports those intervals. Question #4 – The SDT believes that entities cannot be expected to initially have data for requirements that did not previously exist. Question #7 – From a mandatory perspective, this is dependent on the regional BES definitions and on what those definitions may describe to be “transmission Protection Systems.” • The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1. Time Horizon – Thank you for your input.

Comment:	1. There is no reliability based justification to alter the standards to require practices of a subset of entities as allowable intervals. It is incredible that the standard would suppose that requiring the use of weighted average practice of some subset of all entities could reasonable. The purpose of a reliability standard is to ensure the reliability of the BES. There is no indication that the existing standard has posed a threat to the reliability of the BES. There is no data which indicates that the BES reliability is impacted because of certain maintenance practices. The SDT has chosen an approach which has statistical merit and is good information for entities to consider in reviewing their maintenance program. To force an entity to enhance its maintenance program because some subsets of entities have a different program is contrary to the purpose authorized by the Energy Policy Act of 2005. The variables of each entity faces when developing their maintenance practice intervals cannot be calculated through statistical analysis. To presume that the end result (the interval itself) can be applied to other entities ignores the sound decisions made internally to each entity that results in final interval. The standard should return to addressing real reliability impacts as required by law. The desire to improve maintenance programs offers a unique problem to the FERC and regulatory world. The knee jerk reaction is to define a "universal" interval based on some statistical method. What happens if the solution is bad, who will accept the consequences that narrow prescription was wrong and the interval caused a reliability impact. It would no longer be the Entity. The standard does not make such an allowance. History is replete with examples of this type of micro managing. Rather than fall into the same trap, and suffer the consequences of the unknown, it is suggested to allow Entities to optimize their programs to ensure reliability of the BES. If the NERC wants to create a reliability based standard that addresses reliability impacts, the SDT is encouraged to create a standard of "disallowed" practices. These would be practices which have a demonstrated impact on reliability. The SDT should spend to analyzing maintenance practices which have a known impact on reliability (as evidenced by disturbance reports) and develop requirements which disallow such practices or range of practices. In addition, if it is shown that an event in which BES reliability was impacted by the utilities PSMP (as evidenced by disturbance reports), the utility would be required to submit to the RRO a corrective action plan which addresses how the PSMP will be revised and when compliance with that PSMP is to be achieved. 2. The intervals prescription for performance based PSMP virtually eliminates the capability of smaller utilities that do not have a large equipment database to justify a performance based system that may be sound based on their experience. This overly prescriptive approach should be eliminated and return to allowing utilities to justify their programs. 3. The Time Horizons are too narrow for the implementation of the standard as written. The SDT appears to

	have not accounted for the data analysis associated with performance based systems. The data collection, analysis, and subsequent decisions associated development of a maintenance program and its justification do not occur overnight especially with larger utilities. In addition, this new standard will require complete rewrite of an entities internal maintenance programs. The internal processes associated with these vary based on the size of the entity and its organizational structure. 4. Since this standard is so invasive into the internal decisions concerning maintenance, the standard should allow at least 18 months for entities to rewrite their internal maintenance programs to meet the program development requirements and 18 months to train the staff in the new program, incorporate the program into the entities compliance processes, and to implement the new program.
Response:	Thank you for your comment. 1. FERC directed the SDT to establish maximum time intervals between maintenance activities. The SDT recognized that different types of equipment, different generations of equipment, different failure modes of equipment, and different versions of time-based maintenance had to be considered. The SDT agrees with the commenter that the Standard allows statistical analysis, and performance-based maintenance allows an entity to create time intervals that could exceed any "weighted-averages" time-based intervals. The Supplementary Reference adds a Section 9 to show how an entity can create a performance-based maintenance interval. 2. FERC directed the SDT to establish maximum time intervals between maintenance activities. Smaller entities may aggregate their component populations with other entities having similar programs – see Section 9 of the Supplementary Reference document and FAQ IV.3.A. Entities are not required to use performance-based PSMPs; this option is made available to entities who wish to use it. 3. Your comment appears to address the Implementation Plan, not Time Horizons. The Implementation Plan for Requirement R1 has been extended from three months to twelve months. For performance-based programs, Attachment A specifies that there must first be acceptable results, and that a time-based program (per the Tables) must be used until then. See FAQ IV.3.B. 4. The Implementation Plan for Requirement R1 has been extended from three months to twelve months.

Comment:	The proposed Standard is overly prescriptive and too complex to be practically implemented. An entity

	making a good faith effort to comply will have to navigate through the complexities and nuances, as illustrated by the extensive set of documents the SDT has provided in an attempt to explain all the requirements and nuances. The need for an extensive “Supplementary Reference Document” and an extensive “Frequently Asked Questions Document”, in addition to 13 pages of tables and an attachment in the standard itself, illustrate that the proposal is too prescriptive and complex for most entities to practically implement. 1. The descriptions for the "type of protection system components" do not appear to be consistent between Tables, 1a, 1b and 1c. 2. The maximum maintenance interval for a lead-acid vented battery is listed at 6 calendar years for performing a capacity test. This type of test has been proven to reduce battery life and an interval of 10 to 12 years would be better. 3. The maximum maintenance interval for "Station DC supply" was set at 3 months. This is too short of a period and 6 months would be better. 4. The control and trip circuits associated with UVLS and UFLS do not require tripping of the breakers but all other protection systems require tripping of the breakers, this appears to be inconsistent? 5. Digital relays have electromagnetic output relays. Do they fall into the electromechanical trip or solid state trip? 6. Need for clarification: The standard indicates that only voltage and current signals need to be verified. Does this mean that voltage and current transformers do not need to be tested by applying a primary signal and verifying the secondary output? 7. With regard to DPs who own transmission Protection Systems, the standard is still very unclear on when a DP owns a transmission Protection System. Many DPs own equipment that is included within the definition of a Protection System; however, ownership of such equipment does not necessarily translate directly into a transmission Protection System under the compliance obligations of this standard. DPs need to know if this standard applies to them and right now, there is no certain way of determining that from within this language or previous versions of this standard.

	8. The phrase "Verify Battery cell-to-cell connection resistance" has entered the table where it did not exist before. On some types of stationary battery units, this internal connection is inaccessible. On other types the connections are accessible, but there is no way to repair them based on a bad reading. And bad cell-to-cell connections within units will be detected by the other required tests. This requirement will cause entities to scrap perfectly good batteries just so this test can be performed, with no corresponding increase in bulk electric system reliability while taking an unnecessary risk to personnel and the environment. And because buying battery units composed of multiple cells allows space saving designs, entities may be forced to buy smaller capacity batteries to fit existing spaces. This may end up having a negative effect on reliability. Suggest substituting "unit-to-unit" wherever "cell-to-cell" is used in the table now. 9. The level 2 table regarding Protection Station dc supply states that level 1 maintenance activities are to be used, but then goes on to give a list of Maintenance Activities that don't match those in level 1. Which activities shall we use? 10. Same situation for Station DC Supply (battery is not used) where the 18 month interval is missing. IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months due to storms and outages must set a target interval of two months thereby increasing the number of inspections each year by half again. This is unnecessarily frequent.
Response:	Thank you for your comments. FERC Order 693 and the approved SAR assign the SDT to develop a Standard with maximum allowable intervals and minimum maintenance activities. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 through 1-5. 2. The SDT disagrees. 3. The SDT disagrees. 4. Your observation is correct. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. This is an intentional difference between UFLS/UVLS and the remainder of the Protection Systems addressed within the Standard, because of the distributed nature of UFLS/UVLS and because these devices are usually tripping distribution system elements 5. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1. 6. Your observation is correct. 7. Your concern seems to be primarily related to the applicable regional BES definition.

	8. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. “Cell” has been replaced with “cell/unit” to address this concern. 9. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. 10. The SDT disagrees. You should complete the activities within the intervals specified.

Organization:	RRI Energy
Member:	Thomas J. Bradish
Comment:	For PRC-005-2, while there is nothing inherently wrong with the requirements, RRI voted affirmative with concern. Our concern is we believe that rather than fixing the issues that caused the 2003 blackout, there is a continual drift to extensive micro-management to take control of every aspect of the entire industry through regulation in the name of reliability. I believe the documentation required to demonstrate 100% compliance to this standard will be a serious challenge to achieve uniformly for so many components across a widely dispersed fleet, especially in the punitive, zero-tolerance compliance world that presently exists. It only takes the things we are in short supply: time, money, and people. It will drive industry to better systems and performance, but there will be a painful price, especially on the development side. An example of the impact of this standard: station power plant batteries are sized to carry large DC loads with the protection system as only a small fraction of the load profile. Rather than performing a risk assessment for station with low capacity factors (for example RRI has a two unit station that had an average capacity factor in 2009 of 1.72%) after the battery slightly crosses over its degradation threshold, there will be no choice but an immediate and expensive replacement. This type of requirement will push many units into pre-mature retirement or mothballing.
Response:	Thank you for your comment.

Organization:	Tampa Electric Co.
Member:	Ronald L Donahey
Comment:	The level of DC circuit testing required every time the relay is tested represents potentially a negative impact to reliability given the complicated control circuitry in an energized station. Even though you take out an element out of service, the DC control circuits are often interconnected for functions such as breaker failure,

	bus and transformer lockouts, etc. This level of testing needs to be done when initial construction but this increase in testing is not justifiable given the reliability risk and cost. TEC's record for misoperations do to circuitry failure does not support this need.
Response:	Thank you for your comment. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. The SDT believes that mechanical solenoid-operated devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-based maintenance is an option to increase the intervals if the performance of these devices supports those intervals.
Segment:	5
Organization:	Salt River Project
Member:	Glen Reeves
Comment:	SRP believes the requirements of the Standard are confusing and may be problematic in determining compliance. We also believe the required functional testing of the breaker trip coil may potentially increase maintenance outages of circuit breakers. In most cases, circuit breaker maintenance outages can be coordinated such that Protection System maintenance and testing can be done simultaneously. However, in some cases this may not be possible. Outages of any BES facility whether planned or unplanned can impact system reliability. SRP suggests that trip coil monitoring devices be included as an acceptable means of ensuring the trip coil is functioning properly. This will help to avoid unnecessary outages.
Response:	Thank you for your comment. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. The SDT believes that mechanical solenoid-operated devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-based maintenance is an option to increase the intervals if the performance of these devices supports those intervals.

Comment:	Functional testing is impractical.

Response:	Thank you for your comment. Functional testing is not the only means of completing the required maintenance, although it may be the most practical.
Segment:	3
Organization:	JEA
Member:	Garry Baker
Comment:	JEA does not believe the standard adequately addresses issues like component, FAQ, etc as identified below: 1. R1.1 Identify all Protections System components. What is meant by Protection System component? Is a component a wire, contact, device, etc. A list of components as intended by the SDT would be illustrative in understanding the SDT's intent of what a component includes. 2. Are the FAQ and Supplemental Reference going to be adopted as part of this standard? These documents contain information that is critical to the proper understanding and interpretation of the standard, thus either the standard needs to be rewritten to include this information, or the FAQ and Supplemental Reference need to be adopted as part of this standard. Any inconsistencies between the FAQ and the standard, as written, would need to be corrected. 3. The maximum maintenance interval for a lead-acid vented battery is listed as 6 calendar years for performing a capacity test. This type of test has been proven to reduce battery life and a longer capacity test interval of 10 to 12 years would be better, allowing for longer battery life. 4. The implementation period for R1.1 of 3 months is too short and should be extended to one calendar year; of course this is dependent on the complexity of items listed as part of the definition of "Protection System component."
Response:	Thank you for your comment. 1. A definition of "Component" has been added to the draft Standard. The SDT's intent is that this definition will be used only in PRC-005-2, and thus will remain with the Standard when approved, rather than being relocated to the Glossary of Terms. 2. These documents provide supporting discussion, but are not part of the Standard. The SDT intends that these be posted as Reference Documents, accompanying the Standard.

	3. The SDT disagrees. 4. The Implementation Plan for Requirement R1 has been modified from three months to twelve months.
Segment:	5
Organization:	Public Utility District No. 1 of Lewis County
Member:	Steven Grega
Comment:	1. As written PRC-005-2 does not recognize or accommodate the many type of batteries in use at substations. To accommodate many of the prescribed tests, the batteries would have to be disassembled to conduct the test with little valuable information gained. Suggest wording only saying the batteries should be periodically test to assure that they perform as designed. Let the entities' engineers decide on what is most appropriate for their batteries. 2. Having a standard that requires 100% compliance on 1000's of components is a good way of assuring many violations. Most protective system can function with half the protection in service. Typically most engineers over design and have backup upon backup on critical elements. Suggest standard require a lesser compliance rate; say 90% to 95% during an audit. The elements not in compliance could be followed by a 12 month plan to bring other elements into compliance but the entity at 90% to 95% would still be found compliant. In summary, this proposed standard has gone beyond the reasonably level of regulation by NERC. Therefore, I am voting not to affirm the revision to this standard.
Response:	Thank you for your comment. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. 2. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation.
Segment:	3
Organization:	City of Farmington
Member:	Linda R. Jacobson
Comment:	As written, is opens up the PRC-005 standard to Technical Feasibility Exceptions because some batteries are not able to accommodate all of the tests proscribed in the draft standard as explained by Steve Alexanderson in a prior e-mail to the ballot pool. The draft standard would cause NERC to regulate through the standards

	battery testing, DC circuit testing, etc. on distribution elements with no significant improvement to BES reliability, which is beyond the statutory scope of the standards
Response:	Thank you for your comment. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. “Cell” has been replaced with “cell/unit” to address this concern. The Standard only addresses distribution-located devices to the degree that they address BES issues. UFLS and UVLS per the relevant NERC Standards are frequently implemented on the distribution system.

Organization:	Pacific Gas and Electric Company
Member:	Chifong L. Thomas
Comment:	The requirements in the latest draft are confusing and at times seem to be in conflict with other requirements. From a compliance and enforcement perspective, this confusion would make the standard difficult to audit. 1. We are concerned over R1.1, where all components must be identified, without a definition for the word component or the granularity specified. While the FAQ gives a definition, and allows for entity latitude in determining the granularity, the FAQ is not part of the standard. We are concerned whether identification is required for every individual component, such as each auxiliary relay, or is it sufficient that the auxiliary relays are included within the scheme that is being tested and documented. Do the auxiliary relays need to be documented within the maintenance database and/or on the actual test reports of schemes being tested? We suggest that the FAQ definitions be included within the standard. 2. We agree with most of the changes from the last draft in Table 1a, 1b and 1c. However, the phrase “Verify Battery cell-to-cell connection resistance” has entered the table where it did not exist before. On some types of stationary battery units, this internal connection is inaccessible. On other types the connections are accessible, but there is no way to repair them based on a bad reading. And bad cell-to-cell connections within units will be detected by the other required tests. This requirement will cause entities to scrap perfectly good batteries just so this test can be performed, with no corresponding increase in bulk electric system reliability while taking an unnecessary risk to personnel and the environment. And because buying battery units composed of multiple cells allows space saving designs, entities may be forced to buy smaller capacity batteries to fit existing spaces. This may end up having a negative effect on reliability. Suggest substituting “unit-to-unit” wherever “cell-to-cell” is used in the table now.

	3. The level 1 table regarding Control and trip circuits with electromechanical trip or auxiliary contacts now includes exception for microprocessor relays, but there is no listing for the requirements for microprocessor relays. 4. The level 2 table regarding Protection Station dc supply states that level 1 maintenance activities are to be used, but then goes on to give a list of Maintenance Activities that don't match those in level 1. Which activities shall we use? 5. Same situation for Station DC Supply (battery is not used) where the 18 month interval is missing.
Response:	Thank you for your comment. 1. Requirement R1, part 1.1, has been revised to state, "Address all Protection System component types" in consideration of your comment. 2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. "Cell" has been replaced with "cell/unit" to address this concern. 3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 and 1-5. 4. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. 5. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4.
Segment:	5
Organization:	Pacific Gas and Electric Company
Member:	Richard J. Padilla
Comment:	The level of detail of this standard is over the top and currently conflicts with other standards and is open for future conflicts. We recommend that the standard DT evaluate the basic rational for the standard and limit its scope. Some examples are: 1. As written, is opens up the PRC-005 standard to Technical Feasibility Exceptions because some batteries are not able to accommodate all of the tests proscribed in the draft standard as explained by Steve Alexanderson in a prior e-mail to the ballot pool. The draft standard would cause NERC to regulate through the standards battery testing, DC circuit testing, etc. on distribution elements with no significant

	improvement to BES reliability, which is beyond the statutory scope of the standards 2. The standard unreasonably retains the "100% compliance" paradigm for thousands, if not millions of protection system components as written, the standard requires testing of batteries, DC control circuits, etc., of distribution level protection components associated with UFLS and UVLS. UFLS and UVLS are different than protection systems used to clear a fault from the BES. An uncleared fault on the BES can have an Adverse Reliability Impact and hence; the focus on making sure the fault is cleared is important and appropriate. However, a UFLs or UVLS event happens after the fault is cleared and is an inexact science of trying to automatically restore supply and demand balance (UFLS) or restore voltages (UVLS) to acceptable levels. If a few UFLS or UVLS relays fail to operate out of potentially thousands of relays with the same function, there is no significant impact to the function of UFLS or UVLS. Hence, there is no corresponding need to focus on every little aspect of the UFLS or UVLS systems. Therefore, the only component of UFLS or UVLS that ought to be focused on in the new PRF-005 standard is the UFLS or UVLS relay itself and not distribution class equipment such as batteries, DC control circuitry, etc., and these latter ought to be removed from the standard. 3. In addition, most distribution circuit are radial without substation arrangements that would allow functional testing without putting customers out of service while the testing was underway, or at least without momentary outages while customers were switched from one circuit to another. Therefore, as written, we would be sacrificing customer service for a negligible impact on BES reliability
Response:	Thank you for your comment. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. “Cell” has been replaced with “cell/unit” to address this concern. The Standard only addresses distribution-located devices to the degree that they address BES issues. UFLS and UVLS per the relevant NERC Standards are frequently implemented on the distribution system. 2. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. 3. Functional testing is not the only means of completing the required maintenance, although it may be the most practical.

Comment:	As discussed at the FERC Technical Conference on Standards Development, the goal of the standards

	program is to avoid or prevent cascading outages--specifically not loss of load. The expansion of this standard deviates significantly from its purpose of maintaining protective systems that affect BES reliability. It doesn't recognize that not all relays affect reliability. If reliability is measured by a Reportable Disturbance, then the threshold varies by control area--largest contingency. The standard should include a process, not unlike the risk based assessment in CIP-002-2 R1, to include as "identified components" only those affecting reliability. All of the various reliability criteria should be considered.
Response:	Thank you for your comment. "BES reliability" is more than simply avoiding "cascading outages" – as illustrated by the approved definition of "Adequate Level of Reliability" as promulgated by the NERC Planning and Operating Committees in response to a directive from FERC, and as described in Section 215 of the Federal Power Act.

Comment:	1. Draft is confusing & seems to conflict with other requirements. Table 1b Maint. Activities needs to define whether all protection logic or conditions would initiate a relay trip output are required to be simulated & tested to the relay tripping output contact. 2. The Attachment A definition of "common factors" is way too broad to be utilized in defining a grouping of protection system devices.
Response:	Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 2. The SDT is not clear whether your concern is about "common factors" as used in the definition of "Segment." See Section 9 of the Supplementary Reference document for a discussion of performance-based maintenance.

Comment:	1. Table 1a, Protective Relays: Change 1st line to: "Test and calibrate if necessary the relays…"

	Table 1a & 1b, Protective Relays: 3rd line: Change “check the relay inputs…” to “verify the relay inputs…” The term “check” is not defined, whereas “verify” is. Tables 1a & 1b We agree that six / twelve years is an acceptable interval for relay maintenance. Table 1a & 1b, Control & Trip Circuits: The proposed addition to require tripping circuit breakers during Protection System maintenance will require outages and is therefore detrimental to BES reliability and should be removed. – Generating unit protection system maintenance is done during scheduled outages. The high voltage breaker on a generating unit often remains energized to back feed and supply station auxiliaries when the generator is offline. The proposed requirement will increase the amount of equipment requiring an outage for maintenance, and possibly the length of the outage, resulting in significantly more equipment out of service as well as increased costs. This requirement also results in greater maintenance efforts and costs when there are redundant protection system equipment (breaker trip coils, lockout relays, etc), which is contrary to good practice and reliability. – Many of the breakers that We Energies, as the Distribution Provider, trips from its BES protection systems are not owned by We Energies and are owned by a separate transmission company. The trip testing and maintenance of the transmission company may not coincide with our relay maintenance testing program. The standard shall have allowances for the entity to ONLY test or maintain equipment that it OWNS! Table 1a, Station dc supply: – The activity to verify the state of charge of battery cells is too vague, and requires more specific action. We assume that the drafting committee is recommending specific gravity measurements. Specific gravity measurements have not been shown to be an accurate indicator of state of charge. In addition, as shown in the nuclear power industry, there is no established corrective action that is taken based on specific gravity results (eg. Don’t require a test where there is no acceptable corrective action). – The activities to “verify battery continuity” and “check station dc supply voltage” are also vague and need to be more clearly specified what is intended. – The 3 month time interval for battery impedance testing is too frequent. 18 month or annual testing is more appropriate.

	– The 3 calendar year performance or service test is too frequent and will actually remove life from a battery and reduce reliability. Recommend capacity testing no more that every 5 years and more frequent test if the capacity is within 10% of the end of life or design. This is consistent with the nuclear power industry. Table 1b, Station dc supply: – Recommend a change or addition to Table 1b - Recommend a level 2 monitoring (not just a default to the level 1 maintenance activities) which allows for the removal of quarterly "check" of electrolyte levels, DC supply voltage, and DC grounds - if station DC supply (charger) voltage is continuously monitored (eg. one should not have detrimental gassing of a battery if the float voltage of the battery is properly set and monitored). Table 1a, Associated communications systems: The requirement to verify functionality every three months is excessive; verifying this every twelve months is adequate. Tables 1a & 1b – Although the latest standard provided some additional clarification, more clarification is required on what maintenance / testing is ONLY required for UFLS/UVLS protection systems vs. BES protection systems (eg. UFLS / UVLS systems – Is a verification of proper voltage of the DC supply the only battery or DC supply test required (e.g. no state of charge, float voltage, terminal resistance, electrolyte level, grounds, impedance or performance test, etc.) – The requirement to retain data for the two most recent maintenance cycles is excessive. The required data should be limited to the complete data for the most recent cycle, and only the test date for the previous cycle. 2. We Energies does not agree to the implementation plan proposed. While it makes common sense to proceed with R1 prior to proceeding with implementing R2, R3, and R4, the timeline to be compliant for R1 is too short. It will take a considerable amount of resources to migrate the maintenance plan from today's standard to the new standard in phase one. ATC recommends that time to develop and update the revised program be increased to at least one year followed by a transition time for the entity to collect all the necessary field data for the protection system within its first full cycle of testing. (In ATC's case would be 6 years) To address phase two, We Energies believes human and technological resources will be

	overburdened to implement this revised standard as written. The transition to implementing the new program will take another full testing cycle once the program has been updated. Increased documentation and obtaining additional resources to accomplish this will be challenging. Implementation of PRC-005-2 will impact We Energies in the following manner: a. Increase costs: double existing maintenance costs. b. Since there will be a doubling of human interaction (or more), it is expected that failures due to human error will increase, possibly proportionately. c. Breaker maintenance may need to be aligned with protection scheme testing, which will always contain elements that are include in the non-monitored table for 6 yr testing. d. We Energies is developing standards for redundant bus and transformer protection schemes. This would allow We Energies to test the protection packages without taking the equipment out of service. Further if one system fails, there is full redundancy available. With the current version of PRC-005-2, We Energies would need to take an outage to test the protection schemes for a transformer or a bus; there is not an incentive to install redundant schemes. We Energies is working with a condition based breaker maintenance program. This program's value would be greatly diminished under PRC-005-2 as currently written. 3. Consideration also needs to be given for other NERC standards expected to be passed and in the implementation stage at the same time, such as the CIP standards.
Response:	Thank you for your comment. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 2. The Implementation Plan for Requirement R1 has been changed from three months to twelve months. 3. This issue should be presented to the NERC Standards Committee.

Comment:	1. In Table 1a section-Station DC Supply – 18 calendar months, under Maintenance Activities column, suggest changing under Verify: Battery terminal connection resistance To: Entire battery bank terminal connection resistance (This could have been interpreted as individual batteries) And change: Battery cell-to-cell connection resistance To: Battery cell-to-cell connection resistance, where an external mechanical connection is available. 2. In Table 1a-Station dc supply (that has a component Valve Regulated Lead-Acid batteries) suggest changing Max Maintenance Interval=3 Calendar Years or 3 Calendar Months to 4 Calendar Years or 12 Calendar Months. Our concern is that the insurance companies may push NERC maintenance intervals on all battery banks not associated with the BES. 3. Table 1a-Station dc supply (that has as a component Lead-Acid batteries) Max Maintenance Interval=6 Calendar Years suggest changing to 10 Calendar Years. Reason: performance tests may degrade the battery. 4. Table 1a-Station dc supply (that has as a component Nickel-Cadmium batteries) Max Maintenance Interval=6 Calendar Years suggest changing to 10 Calendar Years. Reason: performance tests may degrade the battery. 5. Table 1b -Level 2 Monitoring Attributes for Component in the row labeled (Control and trip circuitry) we suggest the following change: If a trip circuit comprises multiple paths, at least one of those paths is monitored. Alarming for loss of continuity or dc supply for trip circuits is reported to a location where action can be taken. 6. While all tripping circuits are not completely monitored, the trip coils and the outdoor cable runs are completely monitored. The only portion that would not be monitored is a portion of inter and intra-panel wiring having no moving parts located in a control house. Our company has extremely low failure rate of panel wiring and terminal lugging. I don’t think that there is provision for moving control and trip circuitry to performance based maintenance? This control circuitry should be maintained less frequent than un-monitored trip circuits (6 years).

Response:	Thank you for your comment. 1.The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. This element of the table has been modified to state, “Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)” to address this comment. 2. NERC Standards are limited to facilities and equipment related to the BES. How the Standard may be otherwise used is outside the scope of NERC Standards. 3. The SDT disagrees, and believes that a performance test at 6-year intervals is appropiate for Vented Lead Acid and Ni-Cad batteries. A properly maintained battery, according to various credible references (from IEEE, EEI, EPRI, various manufacturers, etc.), can easily handle multiple deep discharges over its expected life. 4. The SDT disagrees, and believes that a performance test at 6-year intervals is appropiate for Ni-Cad batteries. A properly maintained battery, according to various credible references (from IEEE, EEI, EPRI, various manufacturers, etc.), can easily handle multiple deep discharges over its expected life. 5. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-56. The Tables have been rearranged and considerably revised to improve clarity. Comment:	1. There is not enough clarity to clearly identify which protection system components are necessary to protect the BES. We suggest that 4.2.1 be revised to read “protection systems that are designed to provide protection for the BES.” 2. The Standard does not provide a grace period if an entity is unable to meet the maintenance requirement for extenuating circumstances. For example if an entity has to divert maintenance resources to storm restoration. We do not believe the reliability of the Bulk Electric System will be compromised if an entities' maintenance program slips by a few months due to extreme events, especially if it is brought back on track within a short time frame. 3. We are opposed to the six calendar year maximum maintenance interval for microprocessor relays that have auxiliaries.

Response:	Thank you for your comment. 1. The SDT disagrees and believes that the Applicability is correct as stated. 2. “Grace periods” within the Standard are not measurable, and would probably lead to persistently increasing intervals. However, an entity may establish an internal program with grace-period allowance, as long as the entire program (including grace periods) does not exceed the intervals within the Standard. 3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1.

Comment:	The draft standard expects 100% compliance for millions of protection system components at all times. The standard should consider a statistically based performance metric instead of a performance target that expects 100% compliance.
Response:	Thank you for your comment. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation.
Segment:	1
Organization:	Public Service Company of New Mexico
Member:	Laurie Williams
Comment:	Overall, the inclusion of several types of protective relay systems into one standard is reasonable and should include those associated with UVLS and UFLS. Even so, the standard is unmanageably cumbersome with far too many details. Although it has been said that protection systems include the instrument transformers, DC system and sometimes the breaker trip coils it is equally as true to say that the protective relay systems depend on those to effectively respond to the anomaly, typically a short circuit fault. With that said it is those item’s maintenance that should potentially be moved to different standards to improve clarity. Their inclusion into this standard by size and complexity overwhelms this standard. This standard should include only those items that utilize similar equipment and techniques to maintain. In this case and at this time that means computer-controlled test sets that also generate the records necessary to prove compliance. Even after distilling the standard to only protective relay systems the complexities and details used to explain

	the non-time-based methodologies contribute to the confusion. But the availability of those methodologies is important and probably cannot be in a different standard. It therefore seems imperative with the inclusion of those methodologies that the DC support system maintenance and instrument transformer maintenance have different standards. The inclusion of so much explanation inside the standard is distracting and perhaps contributes to the confusion. PNM also offers the following specific feedback on the proposed standard: 1. -R1.1: Uniquely identifying 'Protection System components' as asked for in R1.1 may be problematic given protective systems may be logged in maintenance databases as packages rather than individual elements. Because the elements within each package are tested as a group, the requirement to individually list the components of the package and track them as such would provide no additional benefit to system reliability. 2. -The activities outlined in Tables which begin on Page 9 of the proposed Standard are difficult to align with the VSLs given in the standard. 3. -The Tables suggest that test trips of equipment are required as part of the scheduled program, but test trips of equipment may pose a hazard to the BES if the equipment fails due to multiple test trips or mis-operates to remove additional BES facilities from service (ex., breaker failure mis-operation during line relay trip testing), which may pose a potential risk to the BES. An example would be 8 test trips of a generator breaker in order to make it through the testing of all of the system components that have the ability to trip the generator lockout and therefore the breaker. Suggest wording to be added that would include some sort of breaker tripping simulation (test box, lockout simulator, etc.) that could be built into the circuit? 4. -It is still unclear how the audit of an entity's compliance which occurs during the transition time will be viewed if it chooses to immediately transition all of its components to the intervals defined in the standard, but were out of the interval defined by the entity under PRC-005-1? 5. -From the Table 1a – "Verify proper function of the current and voltage signals" is not defined. Is the verification visual? How is this easily measured on circuits with EM relays still in service? 6. -If exposure to BES is evident during a testing interval, how does the TO or GO coordinate with its

	Reliability Coordinator to delay or push out testing that may compromise the testing due date? Example – critical transmission circuit is removed from service under forced outage, testing due on adjacent or other critical circuit where test tripping could compromise BES. What is the documentation procedure to get an exception or coordinate with RC to mitigate? This has been a big hole in any testing program; there is no way to file an exception due to unforeseen circumstances like this one. 7. -Is it recommended that there be on PSMP per Company no matter how many Entities they may have or should there be one PSMP for each entity? Standard is unclear on this issue.
Response:	Thank you for your comment. 1. Requirement R1, part 1.1, has been revised to state, "Address all Protection System component types" in consideration of your comment. 2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. The VSLs have been modified to correspond. 3. The Standard allows functional testing, if used, to be done in overlapping segments to avoid specifically the situations you cite. 4. This is a concern that should be submitted to the compliance monitor. 5. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3. Also please see Section 15.2 of the Supplementary Reference and FAQ II.3.A, II.3.B, II.3.C, and II.3.D. 6. It would seem prudent to schedule your maintenance to allow for such contingencies. "Grace periods" within the Standard are not measurable, and would probably lead to persistently increasing intervals. However, an entity may establish an internal program with grace-period allowance, as long as the entire program (including grace periods) does not exceed the intervals within the Standard. 7. This is up to the entity. For example, you may choose to have one PSMP for a transmission function and a separate one for a generation function.

Organization:	PPL Electric Utilities Corp.
Member:	Brenda L Truhe
Comment:	PPL EU is voting negative because the definition of Protective Relays is not limited to only those devices that use electrical quantities as inputs (exclude pressure, temperature, gas, etc).
Response:	Thank you for your comment. The Standard does not preclude entities from maintaining such devices or

	including them in their PSMP.
Segment:	1, 3
Organization:	Platte River Power Authority
Member:	John C. Collins, Terry L Baker
Comment:	The standard is very difficult to interpret even with all of the supplemental documentation and we believe this will lead to more non-compliance of the standard without any increase to system reliability and in some cases the required testing will actually reduce system reliability by putting the system at unnecessary risk to complete the testing.
Response:	Thank you for your comment. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5.
Segment:	1
Organization:	Nebraska Public Power District
Member:	Richard L. Koch
Comment:	The negative vote is based upon functional trip checking and the affect that it will have on the BES.
Response:	Thank you for your comment. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5, which no longer includes any specific requirements for functional testing. Performance-based maintenance can also be applied to these functions.
Segment:	1
Organization:	National Grid
Member:	Saurabh Saksena
Comment:	1. National Grid does not agree with the proposed implementation plan. The time provided for the first phase “at least six months” is too open ended and does not give entities a clear timeline. National Grid suggests 1 year for the first phase. National Grid also suggests phasing out the second phase in stages. 2. National Grid does not support the VSL criteria based on "total number of components". Calculating total number of components will be hugely costly and does not enhance any reliability. It will also take away the much needed resources required for maintenance.
Response:	Thank you for your comment.

	1. This comment appears to be related to the Implementation Plan for the definition (which was independent to the Standard), not to the Standard. 2. The SDT believes that the only alternative to these criteria is to provide a binary VSL, which would mean that any non-compliance would be "Severe".
Segment:	3
Organization:	Niagara Mohawk (National Grid Company)

Segment:	1, 3
Organization:	MidAmerican Energy Co.
Member:	Terry Harbour, Thomas C. Mielnik
Comment:	For control and trip circuit maintenance the requirement includes "a complete functional trip test". In order to accomplish this type of testing given current design of lock-out relay and interrupting device trip circuitry multiple breakers and line terminal outages would be required simultaneously. In addition this type of testing has the potential to result in unintentional tripping of equipment that could cause equipment damage and customer outages. Segmentation of trip circuits by lifting wires has the potential for incorrect restoration following testing. This type of testing has the potential to degrade system reliability as multiple entities schedule this work. An alternate to complete functional testing that does not potentially degrade system reliability should be substituted.
Response:	Thank you for your comment. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5, which no longer includes any specific requirements for functional testing. Performance-based maintenance can also be applied to these functions. Electromechanical devices such as aux or lockout relays remains at 6 years, as these devices contain "moving parts" which must be periodically exercised to remain reliable.

Segment:	1
Organization:	Idaho Power Company
Member:	Ronald D. Schellberg
Comment:	Monitoring the state of charge using current measurement methods would increase the workload and staffing requirements beyond what we feel is necessary with little additional value to reliability beyond specific gravity measurements.
Response:	Thank you for your comment. The Standard is requiring that state-of-charge be determined, but does not specify how. Specific gravity testing (no longer required within the Tables) would be one method.
Segment:	1
Organization:	Commonwealth Edison Co.
Member:	Daniel Brotzman
Comment:	1. Nuclear generators are licensed to operate and regulated by the Nuclear Regulatory Commission (NRC). Each licensee operates in accordance with plant specific Technical Specifications (TS) issued by the NRC which are part of the stations' Operating License. TS allow for a 25% grace period that may be applied to TS Surveillance Requirements. Referencing NRC issued NUREGs for Standard Issued Technical Specifications (NUREG-143 through NUREG-1434) Section 3.0, "Surveillance Requirement (SR) Applicability," SR 3.02 states the following: "The specified Frequency for each SR is met if the Surveillance is performed within 1.25 times the interval specified in the Frequency, as measured from the previous performance or as measured from the time a specified condition of the Frequency is met." The NRC Maintenance Rule (10 CFR 50.65) requires monitoring the effectiveness of maintenance to ensure reliable operation of equipment within the scope of the Rule. Adjustments are made to the PM (preventative maintenance) program based on equipment performance. The Maintenance Rule program should provide an acceptable level of reliability and availability for equipment within its scope. The NRC has provided grace periods for certain maintenance and surveillance activities. Exelon strongly believes that SDT should consider providing this grace period to be in agreement and be consistent with the NRC methodology. Not providing this grace period will directly affect the existing nuclear station practices (i.e., how stations schedule and perform the maintenance activities) and may lead to confusion as implementing dual requirements is not the normal station process. Nuclear generating stations have refueling outage schedule windows of approximately 18 months or 24 months (based on reactor type). If for some reason the schedule

	window shifts by even a few days, an issue of potential non-compliance could occur for scheduled outage-required tasks. The possibility exists that a nuclear generator may be faced with a potential forced maintenance outage in order to maintain compliance with the proposed standard. For the requirements with a maximum allowable interval that vary from months to years (including 18 Months surveillance activities), the SDT should consider an allowance for NRC-licensed generating units to default to existing Operating License Technical Specification Surveillance Requirements if there is a maintenance interval that would force shutting down a unit prematurely or face non-compliance with a PRC-005 required interval. Therefore, at a minimum, maintenance intervals should include an allowance for any equipment specifically controlled within each licensee's plant specific Technical Specifications to implement existing Operating License requirements if such a conflict were to occur. 2. Additionally we are requesting to have the first phase of implementation extended from 6 months to 1 year. This will provide adequate time for development of documentation, training for all personnel, and testing the implementation of the new process (es).
Response:	Thank you for your comments. 1. The SDT understands that nuclear power plants are licensed and regulated by the NRC, has a general understanding of the role that plant Technical Specifications (TS) and associated Surveillance Requirements (SR) play in the facilities' operating licenses, and has tried to be sensitive to potential conflicts between PRC-005-2 and NRC requirements. The SDT believes that the majority of components making up the Protection Systems for in-scope generating facilities as discussed in Section 4.2.5 of the Standard would be considered balance of plant equipment and, therefore, not subject to NRC issued TS and associated SR requirements. While availability of plant auxiliary sources to the plant's safety related equipment is addressed by TS and associated SR requirements, these documents are focused on the effects that the availability of these transformers have on reactor safety rather than specifying maintenance and testing requirements for the Protection Systems for these transformers. The SDT recognizes that some battery systems may serve as a source of DC power to both reactor

	safety systems and to protection systems discussed in Section 4.2.5. The SDT acknowledges that there might be plant TS and SR applicable to these batteries. However, the SDT believes that the 3-month and 18-month inspection requirements called for in PRC-005-2 would be no more onerous than plant TS requirements for routine online safety system battery inspections and, furthermore, would not necessitate a plant outage. The SDT recognizes that the PRC-005-2 requirement for validating battery design capability via battery capacity testing would require a plant outage. However, it is the opinion of the SDT that the maximum allowed battery capacity testing intervals of not to exceed 6 calendar years for vented lead acid or NiCad batteries (not to exceed 3 calendar years for VRLA batteries) could easily be integrated within the plant's routine 18 month to 2 year interval refueling outage schedule. The SDT believes that PRC-005-2 is complimentary to the NRC Maintenance Rule in that PRC-005-2 requirements allow for the leveraging of the entire electrical power industry experience in establishing minimum maintenance activities and maximum allowed maintenance intervals necessary to ensure reliable protection system performance. Please see Supplemental Reference Section 8.4 for further discussion for the SDT's rationale for exclusion of grace periods. Please see FAQ IV.2.C for further discussion of impact of PRC-005-2 testing requirements on power plant outage schedules. The challenge of integrating PRC-005-2 testing requirements with a plant's outage schedule is not unique to nuclear plants. Finally, the SDT notes that an entity may build grace periods into its own PSMP as long as the maximum allowed time intervals of PRC-005-2 are not exceeded. If an entity wishes to build a 25% grace period into its program, it may do so by setting its program maintenance and testing intervals at <80% of the PRC-005-2 maximum allowable time interval. 2. The Implementation Plan for R1 has been modified to 12 months.
Segment:	1, 3, 6

Comment:	1. The revised definition to Protection System should include the following exception. "Devices that sense non electrical conditions, such as thermal or transformer sudden pressure relays are not included." The Drafting Team has included this note in the standard, but not in the definition. For consistence across the standards, see PRC-004, which references System Protection, the same definition should be used. 2. See Table 1a, Station dc supply. One of the checks is to verify battery cell-to-cell connection resistance. This is not possible in all battery sets. 3. As written, the standard requires testing of batteries, DC control circuits, etc., of distribution level protection components associated with UFLS and UVLS. This is beyond the scope of the Reliability Standards which should focus on the BES. Only include the UFLS or UVLS relays in the program. 4. Revise M1 to reference Protection System definition.
Response:	Thank you for your comment. 1. The definition of "Protection System" has been modified essentially as you suggest. 2. "Cell" has been replaced with "cell/unit." 3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-4 and 1-5.
Segment:	1
Organization:	BC Transmission Corporation
Member:	Gordon Rawlings
Comment:	1. - Purpose unclear "affecting the reliability of the BES" is open to interpretation should read "applied on or designed to provide protection of the BES" 2. - Monitoring levels (1, 2 and 3) are not clear 3. - Maintenance activities are not well defined 4. - Some utilities base their maintenance program on a fiscal year where all scheduled maintenance for the fiscal year must be completed by the end of the fiscal year. It would take considerable effort to switch to end of calendar year with zero improvement in overall reliability.

	5. - For maintenance scheduled in terms of a number of months, requiring that maintenance be completed by the end of scheduled month does not leave much margin if maintenance is delayed for a legitimate reason.
Response:	Thank you for your comment. 1. The purpose can be general; Requirement R1 is worded as you suggest. 2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 through 1-5. 3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 through 1-5. Various sections of the FAQ have provided suggestions about how to conduct the activities in the tables. 4. With the vast array of entities subject to compliance monitoring, it would be very difficult for the ERO to assess compliance for varying "years." Additionally, the SDT understands that most compliance monitors currently request data on a calendar year basis when assessing compliance. 5. The entity is encouraged to schedule the maintenance activities to allow for contingencies.

Organization:	Associated Electric Cooperative, Inc.
Member:	John Bussman
Comment:	There needs to be grace periods for the battery testing of 3 months. Testing a complete transmission system over 3 states in every 3 months and not be one day past due will b a challenge.
Response:	Thank you for your comment. The 3-month maintenance for station dc supply is comprised of inspections that don't require testing.
Segment:	1, 3, 5
Organization:	Arizona Public Service Co., APS
Member:	Robert D Smith, Thomas R. Glock, Mel Jensen
Comment:	1. The generator Facilities subsections 4.2.5.1 through 5 are too prescriptive and inconsistent with sections 4.2.1 through 4. Recommend this section be limited to description of the function as in the preceding sections. 2. In addition, the associated maintenance activities in Table 1 are too prescriptive.

	3. The activities needed to ensure the reliable service of the relay or device should be left up to the discretion of the utility. One example, due to the change to the Protection System definition and establishing a new PSMP with prescriptive maintenance activities relative to the voltage and current sensing devices has created a situation where data from original or prior verification is not available or not at the interval to meet the data retention requirement. Although, methods of determining the integrity of the voltage and current inputs into the relays were used to ensure reliability of the devices met the utilities performance requirements, they may not meet the interval requirement and would then be considered a violation due to changes in the standard. 4. For data requirements, an initial exemption is recommended for the two recent most recent performances of maintenance activities in the first maintenance interval for this component due to the long maintenance interval, the changes in the standard definitions and the prescriptive maintenance activities. 5. Clarification is needed on “Note 1” in Table 1a, which appears to be used to define a calibration failure. How would it be used in Time Based Maintenance? In PRC-005-2 Attachment A: Criteria for a Performance-Based Protection System Maintenance Program, a calibration failure would be considered an event to be used in determining the effectiveness of Performance Based Maintenance. It is unclear in how it will be used in time based maintenance.
Response:	Thank you for your comment. 1. The SDT believes that transmission lines, UFLS, UVLS, and SPS are clear without additional granularity, but that the additional granularity regarding generation plants is necessary. This is illustrated by numerous questions regarding “what is included for generation facilities” relative to PRC-005-1. 2. FERC Order 693 and the approved SAR assigned the SDT to develop a Standard with maximum allowable intervals and minimum maintenance activities. 3. FERC Order 693 and the approved SAR assigned the SDT to develop a Standard with maximum allowable intervals and minimum maintenance activities. It seems reasonable that you cannot be held accountable for a requirement before it becomes effective. 4. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one, as well as data to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted Standard to establish this level of documentation. The Tables have been rearranged and considerably revised to improve clarity, and the cited note removed. Please see new

	Tables 1-5.

Member:	Jason Shaver
Comment:	ATC does not support the existing 2nd Draft of PRC-005-2 Standard because it is our opinion that: • There is a high probability that system reliability will be reduced with this revised standard. • The number of unplanned outages due to human error will increase considerably. • Availability of the BES will be reduced due to an increased need to schedule planned outages for test purposes (to avoid unplanned outages due to human error). • To implement this standard, an entity will need to hire additional skilled resources that are not readily available. (May require adjustments to the implementation timeline.) • The cost of implementing the revised standard will approximately double our existing cost to perform this work. ATC requests that relevant reliability performance data (based on actual data and/or lessons learned from past operating incidents, Criteria for Approving Reliability Standards per FERC Order 672) be provided to justify the additional cost and reliability risks associated with functional testing.
Response:	Thank you for your comment. The SDT believes that performing these maintenance activities will benefit the reliability of the BES.
Segment:	1, 5, 6
Organization:	American Electric Power, AEP Service Corp, AEP Marketing
Member:	Paul B. Johnson, Brock Ondayko, Edward P. Cox
Comment:	AEP supports the progress of this draft standard, largely supports much of the elements within. However, we provide the following summary of the comments provided in response to the most recent (2nd) draft, which we suggest the SDT consider. 1. In Table 1a for the component “Station dc Supply (used only for UVLS and UFLS)”, the interval

	prescribed is "(when the associated UVLS or UFLS system is maintained)" and the activity is to "verify the proper voltage of the dc supply". The description of the interval "(when the associated UVLS or UFLS system is maintained)" needs to be changed. Relay personnel do not generally take battery readings. The interval should read "according to the maximum maintenance interval in table 1a for the various types of UFLS or UVLS relays". The testing does not need to be in conjunction with the relay testing, it is only the test interval that is important, although relay operation during relay testing is a good indicator of sufficient voltage of the battery. 2. The monitoring and/or maintenance activities listed for batteries are not appropriate in Tables 1b and 1c. There are no commercial battery monitors that monitor and alarm for electrolyte level of all cells. Why not move the electrolyte level to the 18 month inspection and actually open the possibility of condition monitoring to commercially available devices? Or give an option to do the electrolyte check at other time intervals (perhaps 12 months) by visual electrolyte inspection and still allow the monitoring of other functions on the listed 6 year schedule using condition monitoring. It makes no sense to prescribe an unattainable condition monitoring solution. The way that the tables are written, there is no advantage to use the charger alarms since battery maintenance requirements are not reduced in any way. 3. In regards to "Measures and Data Retention", the measure includes the entire definition of "Protection System". Remove the definition from the measure and let the definition stand alone in the NERC glossary. 4. In regards to Data Retention, this calls for past 2 distinct maintenance records to be kept. Since UFLS interval can be 12 years, this would mean that we would need to keep records for 24 years. This is not realistic and consideration should be given to choosing a reasonable retention threshold. 5. The "Supplementary Reference" and the "Frequently-Asked Questions" document should be combined into a single document. This document needs to be issued as a controlled NERC approved document. AEP suggests that the document be appended to the standard so it is clear that following directions provided by NERC via the document are acceptable, and to avoid an entity being penalized during an audit if the auditor disagrees with the document's contents. 6. NiCAD batteries should not be treated differently from Lead-Acid batteries. NiCAD battery condition can be detected by trending cell voltage values. Ohmic testing will also trend battery conditions and locate failed cells (although will usually lag behind cell voltages). A required load test is detrimental to the NiCAD

	manufacturer's business, and will definitely hurt the NiCAD business for T&D applications. Historically NiCADs may have been put into service because of greater reliability, smaller space constraints, and wider temperature operation range. "Individual cell state of charge" is a bad term because it implies specific gravity testing. Specific gravity cannot be measured automatically (without voiding battery warranty or using an experimental system), and when it is measured, it is unreliable due to stratification of the electrolyte and differing depths of electrolyte taken for samples. "Battery state of charge" can be verified by measuring float current. Once the charging cycle is over the battery current drops dramatically, and the battery is on float, signaling that the battery has returned to full state of charge. This is an appropriate measure for Level 3 monitoring as float current monitoring is a commercially viable option and electrolyte level monitoring is not. 7. In Table 2b, why is Ohmic testing required if the battery terminal resistance is monitored? Cell to cell and battery terminal resistance should not be monitored because they will be taken in 18 month intervals. This further supports the argument that the battery charger alarms would be sufficient for level 2 monitoring, while keeping an 18 month requirement for Ohmic testing, electrolyte level verification, and battery continuity (state of charge). Automatic monitoring of the float current should be sufficient for level 3 monitoring as it gives state of charge of the string, and battery continuity (detect open cells). Shorted cells will still be found during the Ohmic testing and a greater interval is sufficient to locate these problems.
Response:	Thank you for your comment. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 3. The SDT modified the Measure as you suggested. 4. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one, as well as data to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted Standard to establish this level of documentation. The SDT disagrees that the documents should be combined. The Supplementary Reference is a holistic presentation of rationale and basis for the various elements of the Standard – discussing mostly the "what" behind the requirements. The FAQ, on the other hand, presents responses to specific frequently asked questions, and, as such, offers more-focused advice on specific subjects, and is more of an example/how-to discussion. The FAQ is primarily a means of capturing some of the most prevalent comments offered

	on the Standard by various entities, with the SDT's response. The SDT believes that the format of the FAQ is a more effective means of presenting the included information than it would be to include this information within the text of the Supplementary Reference document. 5. The SDT believes that since the IEEE Stationary Battery Committee has determined that VRLA batteries and Ni-Cad batteries are different enough to require separate IEEE Standards (IEEE 1188 and IEEE 1106, respectively), these battery technologies are different enough to be treated separately within PRC-005-2. The SDT has drawn upon these IEEE Standards, as well as other sources (EPRI, etc) to develop the requirements of PRC-005-2. The trending activity cited has not been shown to be effective for Ni-Cad batteries (see FAQ II.5.G), and thus a performance test must be performed; the performance test may take many forms. The Tables have been rearranged and considerably revised to improve clarity, and all references to specific gravity have been removed. Please see new Table 1-4. Determining the "state of charge" by monitoring the float voltage may be relevant to the overall station battery, but does not provide an indication of the condition of individual cells as required within the new Table 1-4. 6. Battery terminal resistance shows the condition of the external connections, but reveals nothing regarding the internal condition of the individual cells. Measuring the internal cell/unit resistance provides an opportunity to trend the cell condition over time by verifying the electrical path through the electrolyte within the battery. The ohmic testing is not intended to look for open cells/units, but instead at the ability of the individual cell/unit to perform properly. The new Table 1-4 clarifies that, if the electrolyte level is monitored, the internal ohmic testing need only be performed every six years. Please see FAQ II.5.B, II.5,C and II.5.D for a discussion about continuity.

Member:	Kirit S. Shah
Comment:	We commend the SDT for developing a generally clear and well documented second draft. The SDT considered and adopted many industry comments on the first draft. It generally provides a well reasoned and balanced view of Protection System Maintenance, and good justification for its maximum intervals. Ameren generally agrees that this second draft will be beneficial to BES reliability, but several inconsistencies, unclear items, and a couple issues need to be addressed before we will be able to support it. (a)The tables still contain several inconsistencies and items needing clarification

	(b)Implementation of the PSMP must align with the start of a calendar year (c) The expectation of perfection in maintaining the extremely high volume of Protection System parts is inconsistent with accepted engineering practice (a fundamental tenet is that tolerances must be allowed for) (d)The Project 2009-17 interpretation that clarifies the transmission Protection System border must be incorporated. (e)Generating Plant system-connected Station Service transformers should not be included as a Facility because they are serving load.
Response:	Thank you for your comment. a. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. b. The SDT Guidelines, which were endorsed by the NERC Standards Committee in April 2009, establishes that proposed effective dates “must be the first day of the first calendar quarter after entities are expected to be compliant.” The Implementation Plan is in accordance with these guidelines. c. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. d. When the interpretation (Project 2009-17) is approved, the SDT for PRC-005-2 will consider if the interpretation is appropriate for PRC-005-2 and make associated changes. e. The “load” being served by the Station Service Transformer may be essential to operation of the generating plant, and therefore is not the same as general distribution system load. Therefore, the SDT believes that these system components must remain within the Applicability section of the Standard.

Organization:	Florida Power Corporation
Member:	Lee Schuster
Comment:	Progress Energy does not believe that the definition should be implemented separately from and prior to the implementation of PRC-005-2. We believe there should be a direct linkage between the definition’s effective date to the approval and implementation schedule of PRC-005-2. Since this new definition should be directly

	linked to the proposed revised standard, it would be premature to make this new definition effective prior to the effective date of the new standard. We believe that changes to the maintenance program should be driven by the revision of the PRC standard, not by the revision of a definition.
Response:	Thank you for your comment. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "Protection System" and directed that work to close this reliability gap should be given priority. To close this reliability gap the revised definition must be applied to PRC-005-1 as soon as practical - not years from now. The Implementation Plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.

Comment:	1. It appears that some batteries are not able to accommodate all of the tests required in this standard. 2. The standard also unreasonably requires 100% compliance for millions of protection system components.
Response:	Thank you for your comment. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. 2. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation.

Segment:	6
Organization:	Lakeland Electric
Member:	Paul Shipps
Comment:	As written, is opens the standard to Technical Feasibility Exceptions due to some batteries not being able to accommodate all of the tests proscribed in the draft standard
Response:	Thank you for your comment. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. "Cell" has been replaced with "cell/unit" to address this concern. The Standard only addresses distribution-located devices to the degree that they address BES issues. UFLS and UVLS per the relevant NERC Standards are frequently implemented on the distribution system.
Segment:	4
Organization:	Fort Pierce Utilities Authority
Member:	Thomas W. Richards
Comment:	1. The battery test procedure that calls for intra-cell resistance cannot be performed on batteries that have internal cell-to-cell straps. A brief rewording of the requirement would take care of this. We recommend the minimum requirement be changed to measure the internal resistance at the battery terminal. The reading of individual cells is of little use anyway since a bad reading will result in having to replace the entire jar. 2. The draft standard would cause NERC to regulate through the standards battery testing, DC circuit testing, etc. on distribution elements with no significant improvement to BES reliability, which is beyond the statutory scope of the standards. 3. The standard unreasonably retains the "100% compliance" paradigm for thousands, if not millions of protection system components. The audit becomes an investigation at this point and is not feasible even for mid-sized entities that have hundreds of components subject to this standard.
Response:	Thank you for your comment. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. "Cell" has been replaced with "cell/unit" to address this concern. 2. The Standard only addresses distribution-located devices to the degree that they address BES issues. UFLS and UVLS per the relevant NERC Standards are frequently implemented on the distribution system.

	3. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation.

Comment:	The maintenance and testing requirements are too prescriptive and leave little room for an entity to make decisions regarding what type maintenance and testing they deem appropriate. Some of the maintenance and testing methods and intervals as defined in the standard, e.g. the standard calls for a maximum 3 month testing interval for sealed station batteries if performing impedance testing, do not seem to improve reliability at all. The migration from compliance with the present standard to version 2 as prescribed would be a monumental administrative task
Response:	Thank you for your comment. FERC Order 693 and the approved SAR assigned the SDT to develop a Standard with maximum allowable intervals and minimum maintenance activities.

Segment:	5
Organization:	ExxonMobil Research and Engineering
Member:	Martin Kaufman
Comment:	In the past, NERC has taken care to avoid instructing an entity on how to create its compliance program. The draft standard PRC-005-2 departs from this tradition and partially defines a maintenance and testing program that all entities will be required to follow until such a time that the entity has collected enough data to

	implement the performance based method defined in Attachment A. Additionally, some of the maintenance and testing intervals defined in the tables (e.g. station battery testing) mimic industry recommended test intervals instead of defining maximum acceptable testing intervals.
Response:	Thank you for your comment. FERC Order 693 and the approved SAR assigned the SDT to develop a Standard with maximum allowable intervals and minimum maintenance activities.
Segment:	4
Organization:	Y-W Electric Association, Inc.
Member:	James A Ziebarth
Comment:	From Question 1 on the comment form: Many of the changes to the proposed standard are reasonable and improve the clarity of the standard and its requirements. However, Y-WEA concurs with others on their comments regarding the testing of battery cell-to-cell connection resistance. Many types of stationary batteries are actually blocks of two or more cells that are internally connected. This requirement would necessitate either some sort of feasibility exception process (which, as shown by the TFE process with the CIP standards can be very difficult, cumbersome, and time-consuming to develop and administer) or replacement of the batteries in question, which would pose enormous burdens on small entities that must comply with this standard. The language in this requirement should be changed from “cell-to-cell” to “unit-to-unit” in order to avoid these issues. From Question 7 on the comment form: 1. Y-WEA concurs with others regarding the timing of required battery tests. The IEEE standards referenced indicate target maintenance intervals. In order to remain reasonable, then, this compliance standard needs to allow some buffer between a targeted maintenance and inspection interval and a maximum enforceable maintenance and inspection interval. The suggestion of a four-month maximum window is reasonable and should be incorporated into the standard. 2. Y-WEA is also concerned with R1.1’s language indicating that all components must be identified with no defined “floor” for the significance of a component to the Protection System. The SDT cannot possibly expect that a parts list containing every terminal block, wire and jumper, screw, and lug is going to be maintained with every single part having all the compliance data assigned to it, but without clearly stating this, that is exactly the degree of record-keeping that some overzealous auditor could attempt to hold the registered entity to. The FAQ is much clearer as to what is and is not a component and should be considered

	for the standard. 3. Y-WEA also concurs with others' comments regarding the testing of batteries and DC control circuits associated with UFLS relaying. Many UFLS relays are installed on distribution equipment. Furthermore, many distribution equipment vendors are including UFLS functions in their distribution equipment. For example, many recloser controls incorporate a UFLS function in them. These controls and the reclosers they are attached to, however, are strictly distribution equipment. 16 USC 824o (a)(1) limits the definition of the Bulk-Power System to "not include facilities used in the local distribution of electric energy." A distribution recloser and its control clearly fall into this exclusion. 16 USC 824o (i) (1) prohibits the ERO from developing standards that cover more than the Bulk-Power System. As such, the DC control circuitry and batteries associated with many UFLS relaying installations are precluded from regulation under NERC's reliability standards and may not be included in this standard because they are distribution equipment and therefore not part of the Bulk-Power System. The proposed standard needs to be rewritten to allow for this exclusion and to allow for the testing of only the UFLS function of any distribution class controls or relays.
Response:	Thank you for your comment. From Question 1 - The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. This element of the table has been modified to state, "Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)" to address this comment. From Question 7 – 1. The SDT disagrees. You should complete the activities within the intervals specified. 2. Requirement R1, part 1.1, has been revised to state, "Address all Protection System component types" in consideration of your comment. 3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-4 and 1-5.

Organization:	Old Dominion Electric Coop.
Member:	Mark Ringhausen
Comment:	While the SDT has made progress, there are still some areas that need additional work:

	1. Battery testing of the cell to cell should be unit to unit or some other words for battery system locations that do not allow cell to cell testing. 2. Battery checks on a three months period seems to aggressive and should be moved to six months. 3. Clarify your intent to test the CTs and PTs as some commenters have read it that one does not have to test these pieces of equipment per this standard. 4. Require UFLS and UVLS testing to trip the breaker/recloser when this can be done without tripping of load (by-pass is available).
Response:	Thank you for your comment. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. This element of the table has been modified to state, "Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)" to address this comment. 2. The SDT disagrees. You should complete the activities within the intervals specified. 3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3. 4. Segment:	3
Organization:	Public Utility District No. 2 of Grant County
Member:	Greg Lange
Comment:	Although this version is a significant improvement in several areas from the past version there are still several things that need clarification or overhaul. 1. We find an inconsistency between the component based approach to version 2 and the way protective systems are maintained. The description of components still needs work as well. 2. It appears that in the new version battery chargers and cables could be professionally judged to be a part of the circuitry. We don't believe this is the intent, but again leaves too much to the imagination of an overzealous auditor. Truly most of our issues are with the definition, but until that is corrected we cannot vote for either.
Response:	Thank you for your comment. 1. A definition of “Component” has been added to the Standard and the Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 through 1-5. 2. The dc supply component specifically includes battery chargers within the new Table 1-4.
Segment:	3
Organization:	Public Utility District No. 1 of Chelan County

Comment:	Comments: 1. It is still unclear whether relays that respond to mechanical inputs, such as sudden pressure relays, are included in the proposed definition as protective relays. While PRC-005-2 R1 limits the scope of that particular standard to protection systems that sense electrical quantities, it is remains unclear in other standards that use the defined term whether mechanical input protections are included. 2. We suggest that “Protective Relay” also be defined, and that the definition clearly exclude devices that respond to mechanical inputs in line with the NERC interpretation of PRC-005-1 in response to the CMPWG request.
Response:	Thank you for your comment. 1. The definition of Protection System has been modified to specifically limit it to protective relays that

	respond to electrical quantities. 2. IEEE has provided a definition of protective relay, and the SDT sees no need to repeat or change that definition within this Standard.

Comment:	1. Station DC supply testing was set at three months. A six month time based testing interval is reasonable. 2. Maximum maintenance interval for a lead-acid vented battery is listed at six calendar years. This type of test reduces battery life. A 10 to 12 year interval is reasonable. As written this rule would require a TFE that should be administratively unnecessary. 3. Additional clarification is needed in: Control and trip circuits associated with UVLS and UFLS do not require tripping of the breakers but all other protection systems require tripping. Please clarify. 4. Digital relays have electromagnetic output relays - are they categorized as electromechanical or solid state? 5. There needs to be reasonable flexibility based on industry experience in allowing less than 100% perfection in the testing of relays, etc.
Response:	Thank you for your comment. 1. The SDT disagrees. 2. The SDT disagrees. 3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 4. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1. 5. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation.

Comment:	Cowlitz agrees with most of the changes; however there are many issues from the last comment round that needs to be addressed with a response from the SDT. In particular, Cowlitz is concerned with the following: 1. Verify Battery cell-to-cell connection resistance" has entered the table where it did not exist before. On some types of stationary battery units, this internal connection is inaccessible. On other types the connections are accessible, but there is no way to repair them based on a bad reading. And bad cell-to-cell connections within units will be detected by the other required tests. This requirement will cause entities to scrap perfectly good batteries just so this test can be performed, with no corresponding increase in bulk electric system reliability while taking an unnecessary risk to personnel and the environment. And because buying battery units composed of multiple cells allows space saving designs, entities may be forced to buy smaller capacity batteries to fit existing spaces. This may end up having a negative effect on reliability. Suggest substituting "unit-to-unit" wherever "cell-to-cell" is used in the table now. 2. The level two table regarding Protection Station dc supply states that level one maintenance activities are to be used, but then goes on to give a list of Maintenance Activities that don't match those in level one; which activities shall Cowlitz use? Same situation for Station DC Supply (battery is not used) where the 18 month interval is missing. 3. IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months due to storms and outages must set a target interval of two months thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. Cowlitz suggests changing the maximum interval for battery inspections to six calendar months. For consistency, Cowlitz also suggests that all intervals expressed as three calendar months be changed to six calendar months. 4. Cowlitz is concerned over R1.1, where all components must be identified, without a definition for the word component or the granularity specified. While the FAQ gives a definition, and allows for entity latitude in determining the granularity, the FAQ is not part of the standard. Cowlitz believes this will allow REs to claim non-compliance for every three inch long terminal jumper wire not identified in a trip circuit path. Cowlitz suggests that the FAQ definitions be included within the standard. 5. Many Distribution Providers do not own Protection Systems on the transmission side that are active devices, but rather are passive in nature, i.e., fuses. This Standard verbiage will make it necessary for all DPs

	to have a PSMP even if they do not own active Protective Systems that at least states that they have a null listing of components. This is useless paperwork.
Response:	Thank you for your comment. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. This element of the table has been modified to state, "Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)" to address this comment. 2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. 3. The SDT disagrees. You should complete the activities within the intervals specified. 4. Requirement R1, part 1.1, has been revised to state, "Address all Protection System component types" in consideration of your comment. 5. Fuses are not a Protection System component. The SDT is not addressing what an entity that owns no relevant components must do to demonstrate that for compliance.

Comment:	1. If multiple redundant Protection System components, with associated parallel tripping paths, are provided, Table 1a, 1b, and 1c require that each parallel path be maintained, and that the maintenance be documented. Often, these multiple schemes are provided not to meet specific reliability-related requirements, but instead to provide operating flexibility. Testing these likely will require outages, and those outages may result in decreased reliability. Further, the documentation related to maintenance of all paths will be very cumbersome, and will lead to increased compliance exposure simply by its volume. This may perversely lead to entities NOT installing the redundant schemes, resulting in decreased reliability. 2. Many of the activities described in the Tables are not, by themselves, clear. The standard should include sufficient detail such that entities are clear as to what must be done for compliance, rather that relying on supplementary documents for this information. For example, it's not clear, in Table 1a (Station DC Supply), what is meant by, "Verify that the dc supply can perform as designed when the ac power from the grid is not present." Similarly, it isn't clear from the general description within the Tables that components possessing different monitoring attributes within a single scheme may be distinguished such that differing relevant tables

	can be used for the separate components. 3. In Table 1a, Station DC Supply, one of two optional activities is to “Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. Battery assemblies supplied by some manufacturers have the connections made internally, making this option unavailable. Experience with ASME standards show that NERC and SDT members may be jointly and separately liable for litigation by specifying methods that either prefer or prohibit use of certain technologies. 4. Two of the four Maintenance Activities that begin with “Perform a complete functional trip …“ conclude with “… does not require actual tripping of circuit breakers or other interrupting devices. Do the other two such activities therefore require tripping of circuit breakers or other interrupting devices? 5. Performance of the minimum activities specified within Table 1a for legacy systems, particularly regarding control circuits, will require considerable disconnection and reconnection of portions of the circuits. Such activities will likely cause far more problems on restoration-to-service than they will locate and correct. We suggest that the SDT reconsider these activities with regard for this concern. 6. We do not agree that Footnotes within the Standard are an appropriate method of providing information that is important to the application of the Standard. Important information should be provided within the standard text.
Response:	Thank you for your comment. 1. The SDT believes that it is important that all parallel paths be maintained within the indicated interval, and the prescribed interval already considers the reliability benefits of parallel tripping paths. 2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 through 1-5. 3. The use of the term “cell/unit” acknowledges that individual cells may not be accessible, but that assemblies of several cells (into units) may be available instead, and may be used to address this requirement. An acceptable baseline value and follow-on tests may be acceptable for the entire station battery as a single unit. 4. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5.

	5. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. To the degree that performance history for the components within these systems is available, a performance-based program per R3 and Attachment A may be useful in these cases. 6. The SDT removed all footnotes from the Standard.

Comment:	There in insufficient clarity on the Protection System components that are considered Transmission Protection System equipment which require a Distribution Provider (DP) to perform the required maintenance and testing to ensure compliance with the Standard. In certain distribution substations, components of the high voltage source that supply the distribution substation may be considered components of the Electric Bulk System and their associated protection and control systems must be specified, installed, maintained and tested in accordance with the Standard. Clear delineation of Transmission Protection Systems is therefore critical to ensure the reliability of the EPS.

Response:	Thank you for your comment. This is properly a concern regarding your regional BES definition, and the SDT is unable to respond to these concerns.
Segment:	10
Organization:	Northeast Power Coordinating Council, Inc.
Member:	Guy V. Zito
Comment:	1. There is not enough clarity on whether a Distribution Provider (DP) will be able to clearly identify which protection system components it does own and needs to maintain. Many DPs own and/or operate equipment identified in the existing or proposed definition. However, not all such equipment translates into a transmission Protection System. The definition needs clarification on when such equipment is a part of the transmission protection system. 2. Also, the time provided for the first phase "at least six months" is too open ended and does not provide entities with a clear timeline. It is suggested that one year is appropriate for the first phase phasing out the second year in stages. 3. Regarding battery visuals, the suggestion for consideration is it should be changed from 3 months to 6 months. Electrolyte levels of today's lead-calcium batteries are relatively stable for a 6 month period compared to lead-antimony batteries used in the past. 4. The Implementation plan is too short - In many instances it will be impossible to meet, especially if entities have to create, purchase and adopt new databases to track maintenance activities. Often new procedures will have to be written and additional resources justified and hired. It would be more acceptable if a staged approached was taken similar to the DME Standard. 5. Accounting for every component of a protection system will be an enormous overhead and will take away resources from actually doing maintenance. Emphasis should be on systems and not individual components. 6. The Standard does not provide a grace period if an entity is unable to meet the maintenance requirement for extenuating circumstances. For example if an entity has to divert maintenance resources to storm restoration following a major event, slack built into a maintenance program can be eaten up and put the maintenance over the prescribed period. Provision should be made for a mitigation plan to get back on track. We do not believe the reliability of the Bulk Electric System will be compromised if an entities' maintenance

	program slips by a few months due to extreme contingencies, especially if it is brought back on track within a short time frame.
Response:	Thank you for your comment. 1. This is an issue related to the regional BES definition, and the DP needs to consider their equipment in the context of this definition. 2. This comment appears to be related to the Implementation Plan for the definition (which was independent to the Standard), not to the Standard. 3. The SDT disagrees; these activities should be completed as prescribed in the Standard. 4. A staged Implementation Plan is provided for all activities that have prescribed maximum allowable intervals over one year. However, the SDT believes that a staged Implementation Plan for developing the PSMP is impractical, in that an entity cannot reasonably implement a plan until they have developed it. 5. The SDT believes that the only alternative to these criteria is to provide a binary VSL, which would mean that any non-compliance would be Severe. A definition of Component and Component Types have been added to the Standard, and Requirement R1, part 1.1, has been revised to state, "Address all Protection System component types" to assist in this task. 6. "Grace periods" within the Standard are not measurable, and would probably lead to persistently increasing intervals. However, an entity may establish an internal program with grace-period allowance, as long as the entire program (including grace periods) does not exceed the intervals within the Standard.

Comment:	Hydro One is casting a negative vote for the following reasons: 1. There is not enough clarity on whether a Distribution Provider (DP) will be able to clearly identify which protection system components it does own and needs to maintain. Many DPs own and/or operate equipment identified in the existing or proposed definition. However, not all such equipment translates into a transmission Protection System. 2. The proposed definition of Protection System needs clarification on when such equipment is a part of

	the transmission protection system. Emphasis should be on systems and not individual components. 3. The time provided for the first phase "at least six months" is too open ended and does not provide entities with a clear timeline. It would be more acceptable if a staged approach was taken. 4. The Standard does not provide a grace period if an entity is unable to meet the maintenance requirement for extenuating circumstances. For example if an entity has to divert maintenance resources to storm restoration following a major event, slack built into a maintenance program can be eaten up and put the maintenance over the prescribed period. Provision should be made for a mitigation plan to get back on track. We do not believe the reliability of the Bulk Electric System will be compromised if an entities' maintenance program slips by a few months due to extreme contingencies, especially if it is brought back on track within a short time frame. 5. Table 1a: UFLS/UVLS DC control and trip circuits – Due to the distributed nature of this program, random failures to trip are not impactive to the overall operation of the UFLS protection. There should be no requirement to check the DC portion of these protections any more often than the DC circuit checks associated with that LV breaker. 6. Table 1c: some of the proposed maintenance intervals for station DC supply are too stringent and they would not produce significant increase in reliability to justify associated incremental expenditure.
Response:	Thank you for your comment. 1. This is an issue related to the regional BES definition, and the DP needs to consider their equipment in the context of this definition. 2. This is an issue related to the regional BES definition, and the DP needs to consider their equipment in the context of this definition. It seems that Protection Systems logically need to be maintained on a Component level; definitions of Component and Component Type have been added to assist. 3. This comment appears to be related to the Implementation Plan for the definition (which was independent to the Standard), not to the Standard. 4. “Grace periods” within the Standard are not measurable, and would probably lead to persistently increasing intervals. However, an entity may establish an internal program with grace-period allowance, as long as the entire program (including grace periods) does not exceed the intervals within the Standard. 5. Comment:	1. As written, is opens up the PRC-005 standard to Technical Feasibility Exceptions because some batteries are not able to accommodate all of the tests proscribed in the draft standard 2. The draft standard would cause NERC to regulate through the standards battery testing, DC circuit testing, etc. on distribution elements with no significant improvement to BES reliability, which is beyond the statutory scope of the standards 3. The standard unreasonably retains the "100% compliance" paradigm for thousands, if not millions of protection system components. 4. Will the Standard Introduce Technical Feasibility Exceptions to PRC Standards? A large proportion of the batteries (as high as 50% as reported by some SMEs) are not able to accommodate all of the tests prescribed in the draft standard. Will this necessitate the introduction of TFEs into the process unnecessarily? 5. The Standard Reaches beyond the Statutory Scope of the Reliability Standards As written, the

	standard requires testing of batteries, DC control circuits, etc., of distribution level protection components associated with UFLS and UVLS. UFLS and UVLS are different than protection systems used to clear a fault from the BES. An uncleared fault on the BES can have an Adverse Reliability Impact and hence; the focus on making sure the fault is cleared is important and appropriate. However, a UFLs or UVLS event happens after the fault is cleared and is an inexact science of trying to automatically restore supply and demand balance (UFLS) or restore voltages (UVLS) to acceptable levels. If a few UFLS or UVLS relays fail to operate out of potentially thousands of relays with the same function, there is no significant impact to the function of UFLS or UVLS. Hence, there is no corresponding need to focus on every little aspect of the UFLS or UVLS systems. Therefore, the only component of UFLS or UVLS that ought to be focused on in the new PRF-005 standard is the UFLS or UVLS relay itself and not distribution class equipment such as batteries, DC control circuitry, etc., and these latter ought to be removed from the standard. 6. In addition, most distribution circuit are radial without substation arrangements that would allow functional testing without putting customers out of service while the testing was underway, or at least without momentary outages while customers were switched from one circuit to another. Therefore, as written, we would be sacrificing customer service for a negligible impact on BES reliability. 7. Perfection is Not A Realistic Goal The standard allows no mistakes. Even the famous six sigma quality management program allows for defects and failures (i.e., six sigma is six standard deviations, which means that statistically, there are events that fall outside of six standard deviations). PRC-005 has been drafted such that any failure is a violation, e.g., 1 day late on a single relay test of tens of thousands of relays is a violation. That is not in alignment with worldwide accepted quality management practices (and also makes audits very painful because statistical, random sampling should be the mode of audit, not 100% review as is currently being done in many instances). FMPA suggests considering statistically based performance metrics as opposed to an unrealistic performance target that does not allow for any failure ever. Due to the sheer volume of relays, with 100% performance required, if the standards remain this way, PRC-005 will likely be in the top ten most violated standards for the forever. There is a fundamental flaw in thinking about reliability of the BES. We are really not trying to eliminate the risk of a widespread blackout; we are trying to reduce the risk of a widespread blackout. We plan and operate the system to single and credible double contingencies and to finite operating and planning reserves. To eliminate the risk, we would need to plan and operate to an infinite number of contingencies, and have an infinite reserve margin, which is infeasible. Therefore, by definition, there is a finite risk of a widespread blackout that we are trying to reduce, not eliminate, and, by definition, by planning and operating to single and credible double

	contingencies and finite operating and planning reserves, we are actually defining the level of risk from a statistical basis we are willing to take. With that in mind, it does not make sense to require 100% compliance to avoid a smaller risk (relays) when we are planning to a specified level of risk with more major risk factors (single and credible double contingencies and finite planning and operating reserves).
Response:	Thank you for your comment. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. This element of the table has been modified to state, "Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)" to address this comment. 2. The Standard only addresses distribution-located devices to the degree that they address BES issues. UFLS and UVLS per the relevant NERC Standards are frequently implemented on the distribution system. 3. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. 4. Comment:	IMEA is supportive of the intent of PRC-005-2; however, based on monitoring of comments submitted to date, IMEA would like to see concerns addressed before voting to affirm this proposed standard revision. IMEA supports the comments expressed during ballot pool communications that provisions need to be included to avoid the possible necessity of having to use the burdensome TFE process and to avoid the

	unrealistic expectation of perfection in recordkeeping and exactness of maintenance schedule dates.
Response:	Thank you for your comment. Responses have been provided to the various ballot comments.

Comment:	The SDT has made significant changes to the minimum maintenance activities and maximum allowable intervals within Tables 1a, 1b, and 1c, particularly related to station dc supply and dc control circuits. Do you agree with these changes? If not, please provide specific suggestions for improvement. Comments: 1. Do not agree with the 3 calendar months interval and suggest using quarterly. Both terms require a minimum of four inspections per year have proven to be successful, but the term "quarterly" provides a bit more flexibility than the term "3 calendar months". Given a 3 month maximum interval an entity would need to schedule these tasks every 2 months. 2. As the current requirements are written in R1 of PRC-005-2 Draft, we disagree with the terms identify all Protection System components. We recommend a less prescriptive requirement as listed below. R1.1 Identify BES substations or facilities containing Protection Systems. R1.2 Identify whether Protection Systems per substation or facilities are addressed through time-based, condition-based, performance based or a combination based etc. R1.3 For each substation/facility with Protection Systems include all maintenance activities etc. 3. Listing each individual Protection System component as current draft is onerous and impedes any interpretation of application with very little value. 4. The standard as written will require a great deal of effort by the utilities to maintain 100% compliance as listed. The concern is the power system design allows for some contingencies but the standard allows for no errors. Failing to complete 1% of the maintenance by 1 day infers an entity is out of compliance or in violation. The violations should start for more than a level of 5% not identified, or not maintained. 5. We feel the minor changes of wording as described in R1.1 – R1.3 as listed above will go a long way in

	removing the concerns of the standard. We feel the intent of the standard is sound and request minor changes to facilitate an interpretable standard that sensibly mitigates problems with the BES. As the standard written, the interpretation seems to create a stringent environment with undue compliance requirements. 6. Lastly, the SDT should attempt to embrace Gerry Cauley's vision of "results-based standards" and clearly identify the "risk mitigation objectives, reliability result or outcome" of the revised requirements and allow each entity to meet the outcome and mitigate the risk without writing in such a prescriptive manner which is not preferred. The prescriptive details currently proposed in the standard could then be captured in a reference document.
Response:	Thank you for your comment. 1. The SDT disagrees. Once per calendar quarter would allow up to six months between inspections, while three calendar months limits the effective interval to four months (minus 2 days). 2. Modifying Requirement R1 as you suggest would make it so general that it would be difficult to measure for compliance. Additionally, because of the variety of types of component within a substation, it may be difficult to define a substation-wide (or facility-wide) PSMP that addresses all components and intervals. A definition of Component has been added to the Standard, and Requirement R1, part 1.1, has been revised to state, "Address all Protection System component types". 3. A definition of Component has been added to the Standard to assist; also, Requirement R1, part 1.1, has been revised to state, "Address all Protection System component types" in consideration of your comment. 4. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. 5. As noted above, the SDT believes that Requirement R1 would no longer be measurable. 6. The SDT agrees that the SDT may effectively embrace the "results-based" approach within this Standard; however, doing so at this time would delay development of this high-priority Standard. This is reflected on pages 13-14 of the current draft Standards Development Plan that is out for comment at this time.

Comment:	1. Do not agree with the 3 calendar months interval and suggest using quarterly. Both terms require a minimum of four inspections per year have proven to be successful, but the term “quarterly” provides a bit more flexibility than the term “3 calendar months”. Given a 3 month maximum interval an entity would need to schedule these tasks every 2 months. 2. As the current requirements are written in R1 of PRC-005-2 Draft, we disagree with the terms identify all Protection System components. We recommend a less prescriptive requirement as listed below. -R1.1 Identify BES substations or facilities containing Protection Systems. -R1.2 Identify whether Protection Systems per substation or facilities are addressed through time-based, condition-based, performance based or a combination based etc. -R1.3 For each substation/facility with Protection Systems include all maintenance activities etc. 3. The VRF for R1 ranking should be lower or no greater than R2, R3, and R4. The task of identifying Protection System components has very little to do with increasing reliability of the BES. The implementation of the PSMP most likely will cover all the specific functions of Protection System components although the entity failed to identify all PS components. We recommend the above language changes and agree the requirement adds some value but not a high-risk value to the BES. 4. After correcting the language we feel that a requirement of 100% maintenance on 100% of all components as listed on page 6 of the standard for the VSLs leaves no room for error for systems designed with contingences. The violations should start for more than a level of 5% not identified, not maintained, etc. 5. Listing each individual Protection System component as current draft is onerous and impedes any interpretation of application with very little value. The standard as written will require a great deal of effort by the utilities to maintain 100% compliance as listed. The concern is the power system design allows for some contingencies but the standard allows for no errors. Failing to complete 1% of the maintenance by 1 day infers an entity is out of compliance or in violation. The violations should start for more than a level of 5% not identified, or not maintained. 6. Comment:	The following are the reasons associated with our Negative Ballot. 1. Table 1a contains "Type of Protection System Component" entry "Control and trip circuits with electromechanical trip or auxiliary contacts (except for microprocessor relays, UFLS or UVLS)". However, there is no Component entry for the exception (except for microprocessor relays, UFLS or UVLS). Please add a Component entry with associated intervals and activities for: "Control and trip circuits with electromechanical trip or auxiliary contacts" with a microprocessor relay application. 2. The term "check" has replaced "verify" for some maintenance activities. Replace "verify" with "check" in all locations in the Tables. 3. Redefine "verification" to "A means of determining or checking that the component is functioning properly or maintenance correctable issues are identified". 4. We support this project and believe it is a positive step towards BES reliability. However, we believe the draft document needs additional work as per our comments. Also, as indicated by the amount of industry input on the last version draft comments, we believe revisions are still needed to properly address this technically complex standard. 5. If this standard is to deviate from the original project schedule and follow a fast track timeline for approval, then we disagree with the 3 month implementation for Requirement 1 and ask for at least 12 months. The original schedule provided sufficient advance notice to work on an implementation plan and it included the typical time required for NERC Board of Trustees and regulatory approvals. If the project schedule and typical NERC Board of Trustees and regulatory approval times are to be accelerated, the implementation plan should be extended. We reserve the right to include selected reasons submitted by other Negative balloters for their Negative Ballot.
Response:	Thank you for your comment. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table

	1-5. 2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 3. “Check” is not an element of the PSMP definition. This term, throughout the tables, has been replaced with whatever term of the definition is relevant. 4. Thank you. 5. The Implementation Plan for Requirement R1 has been revised from three months to twelve months.
Segment:	1
Organization:	Empire District Electric Co.
Member:	Ralph Frederick Meyer
Comment:	It is still unclear whether relays that respond to mechanical inputs, such as sudden pressure relays, are included in the proposed definition as protective relays. While PRC-005-2 R1 limits the scope of that particular standard to protection systems that sense electrical quantities, it is remains unclear in other standards that use the defined term whether mechanical input protections are included. We suggest that “Protective Relay” also be defined, and that the definition clearly exclude devices that respond to mechanical inputs in line with the NERC interpretation of PRC-005-1 in response to the CMPWG request.
Response:	Thank you for your comment. The Protection System definition has been revised to explicitly include only protective relays that respond to electrical quantities. This definition applies to all uses of this term within NERC Standards. The SDT feels that the IEEE definition of protective relay is adequate and sees no need to either repeat or change that definition.

Comment:	CSU offers the following comments: With BES still not defined it is difficult to determine what the standard applies to. Requirements are confusing at times, making the standard difficult to audit.
Response:	Thank you for your comment. This concern is a BES concern, and the SDT is unable to address or resolve it.
Segment:	1

Organization:	Avista Corp.
Member:	Scott Kinney
Comment:	Avista has the following comments: 1. The modified definition of Protection System now refers to “functions” rather than “devices.” What are the “functions?” This new term adds confusion without being defined in the standard. 2. Considering all the time spent by Regional Entities and utilities discussing what is meant by monthly, quarterly, annual, etc., this standard should clearly define a Calendar Year and Calendar Month to eliminate any confusion. 3. In general, the requirements of the Standard are very prescriptive and granular which seem counter to the newly adopted NERC philosophy of implementing “performance-based” or “results-based” standards. Specifically, the relay testing requirements are very extensive and not entirely practical when it comes to conducting actual breaker tripping for testing. Also, there are now different maintenance and testing requirements for station batteries depending on the type of battery in service. What’s the real added reliability to the BES to add this complexity to the maintenance program? Considering these observations, is there some real historical research that has gone into determining these requirements? In general, how did the drafting team arrive at the maximum allowable maintenance and testing intervals for inclusion in the Standard, i.e., what is the technical basis for their decisions regarding this?
Response:	Thank you for your comment. 1. “Functions” acknowledge that, while protective relays (or protective devices) is the most common implementation, other devices are now used (particularly in SPSs) that provide these functions from other than traditional relays. 2. A “calendar year” is a single number year on the Gregorian calendar; a calendar month is any one of the twelve months within a single calendar year. Please see Section 8.3 of the Supplementary Reference document. 3. Please see Section 8.3 of the Supplemental Reference document for a discussion of the determination of relay and communications system intervals. For the other components, the SDT studied other sources such as IEEE standard, EPRI documents, visited with various industry experts (such as within IEEE), conducted informal surveys of existing practices, and adjusted to conform to concerns such as generator outage intervals.

Comment:	1. The SDT has made significant changes to the minimum maintenance activities and maximum allowable intervals within Tables 1a, 1b, and 1c, particularly related to station dc supply and dc control circuits. Do you agree with these changes? If not, please provide specific suggestions for improvement. 0 Yes X No Comments: We agree with most of the changes from the last draft. However, the phrase "Verify Battery cell-to-cell connection resistance" has entered the table where it did not exist before. On some types of stationary battery units, this internal connection is inaccessible. On other types the connections are accessible, but there is no way to repair them based on a bad reading. And bad cell-to-cell connections within units will be detected by the other required tests. This requirement will cause entities to scrap perfectly good batteries just so this test can be performed, with no corresponding increase in bulk electric system reliability while taking an unnecessary risk to personnel and the environment. And because buying battery units composed of multiple cells allows space saving designs, entities may be forced to buy smaller capacity batteries to fit existing spaces. This may end up having a negative effect on reliability. Suggest substituting "unit-to-unit" wherever "cell-to-cell" is used in the table now. 2. The SDT has included VRFs and Time Horizons with this posting. Do you agree with the assignments that have been made? If not, please provide specific suggestions for improvement. X Yes 0 No Comments: 3. The SDT has included Measures and Data Retention with this posting. Do you agree with the assignments that have been made? If not, please provide specific suggestions for improvement. X Yes 0 No Comments: 4. The SDT has included VSLs with this posting. Do you agree with the assignments that have been made? If not, please provide specific suggestions for change. 0 Yes X No Comments: It is possible that a component that failed to be individually identified per R1.1 was included by entity A's maintenance plan. This documentation issue gets a higher VSL than entity B that identified a component without maintaining it. We suggest the R1 VSL be change to Low, since we believe lack of maintenance to be more severe than documentation issues. 5. The SDT has revised the "Supplementary Reference" document which is supplied to provide supporting discussion for the Requirements within the standard. Do you agree with the changes? If not, please provide

	specific suggestions for change. X Yes 0 No Comments: 6. The SDT has revised the "Frequently-Asked Questions" (FAQ) document which is supplied to address anticipated questions relative to the standard. Do you agree with these changes? If not, please provide specific suggestions for change. X Yes 0 No Comments: 7. If you have any other comments on this Standard that you have not already provided in response to the prior questions, please provide them here. Comments: The level 2 table regarding Protection Station dc supply states that level 1 maintenance activities are to be used, but then goes on to give a list of Maintenance Activities that don't match those in level 1. Which activities shall we use? 8. Same situation for Station DC Supply (battery is not used) where the 18 month interval is missing. IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months due to storms and outages must set a target interval of two months thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, we also suggest that all intervals expressed as 3 calendar months be changed to 4 calendar months. 9. We are concerned over R1.1, where all components must be identified, without a definition for the word component or the granularity specified. While the FAQ gives a definition, and allows for entity latitude in determining the granularity, the FAQ is not part of the standard. We believe this will allow REs to claim non-compliance for every three inch long terminal jumper wire not identified in a trip circuit path. We suggest that the FAQ definitions be included within the standard.
Response:	Thank you for your comment. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. This element of the table has been modified to state, "Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)" to address this comment. 2. Thank you. 3. Thank you. 4. Requirement R1, part 1.1, has been revised to state, "Address all Protection System component types" and the VSL for Requirement R1 modified in consideration of your comment.

	5. Thank you. 6. Thank you. 7. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. 8. The SDT disagrees; the components should be maintained as specified within the new tables. 9. Requirement R1, part 1.1, has been revised to state, “Address all Protection System component types” in consideration of your comment. Definitions were also added to the Standard for Component Type and Component.

Comment:	LES would like to thank the Drafting Team for its time and effort in developing the standard. However, the standard as currently drafted raises concern as it relates to the identification of all Protection System components. LES asks the Drafting Team to further examine the impact of implementing such a rigorous maintenance program that could potentially impose unnecessary burden and reliability risk with an overly prescriptive approach. Redundancy has been implemented in great detail throughout the history of protection systems to ensure they function as intended. In addition to the comments submitted through the MRO NSRS group comment form, LES would like to further emphasize the following points of contention: (1) Consider revising to consider maintenance activities on a communications channel basis in which intermediate device functioning can be verified by sending a signal from one relay to another. (2) R1, the statement “or are designed to provide protection for the BES” re-opens the argument about transformer protection or breaker failure protection for transformer high-side breakers tripping BES breakers being included in transmission protection systems. (3) Table 1b “breaker trip coil, each auxiliary relay, and each lockout relay” should be changed from a 6 to 12 year interval similar to relay input and outputs. Experience has shown that these both have similar reliability. (4) Include a detailed example of an Inventory List for voltage and current sensing input. (5) Remove “proper functioning of” from the maintenance activities for voltage and current sensing inputs.

	One is not verifying the functionality of the signals. (6) Clarify why control circuitry is stated separately such as in “Control and trip circuits”. This implies that close circuit DC paths are not subjects a PSMP when reclosing and closing of breakers have never before been considered part of a Protection System.
Response:	Thank you for your comment. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-2. Functional end-to-end testing would be one method of completing the necessary verification. 2. This is an issue regarding your regional BES definition, and this SDT is unable to resolve such issues. 3. The SDT believes that mechanical solenoid-operated devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals. 4. The SDT does not understand this comment. The Protection System definition has been changed; perhaps this will help. 5. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3. **6.** This component of the definition is stated to apply as “associated with protective functions” and thus excludes close/reclosing circuits. Please see FAQ II.1.A.

Comment:	1. The six implementation plan is too quick for some entities. A 1 year implementation is recommended. 2. With the addition of all UFLS in this standard, it is implied battery testing, DC circuit testing, etc. on distribution elements are part of the BES. This may lead to every wire and component to be classified as being a part of the BES.
Response:	Thank you for your comment. 1. This comment appears to be focused on the Implementation Plan for the definition, not for the Standard.

	2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-4 and 1-5 for simplified maintenance activities relevant to UFLS.
Segment:	8
Organization:	SPS Consulting Group Inc.
Member:	Jim R Stanton
Comment:	1. I share the concerns expressed by FMPA that the overly prescriptive battery testing requirements will require a TFE process that would be tedious to manage. The standard goes far beyond the scope of Reliability Standards to protect the BES. Reliability Standards should state "what" needs to be done, not "how" to do it. Such overly prescriptive requirements blunt the development of superior and more efficient processes by the industry. 2. Table 1a column "Maintenance Activity" should be renamed "Suggested Maintenance Activity". 3. Tables 1a, b, and c should be reference documents and not referred to in the Requirements. This is especially true since we find terms like "where applicable" and "physical condition" in the tables that forces the Registered Entity to make judgment calls that may not align with the judgment of the auditors. This will mean more interpretation requests and will make the standard extremely difficult to audit as the Registered Entities and auditors compare their "judgments."
Response:	Thank you for your comment. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. This element of the table has been modified to state, "Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)" to address this comment. The SDT has prescribed "what," not "how," except for those rare cases where it is necessary to specify both. 2. The "activities" in the Tables are required, not suggested. 3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 through 1-5. These Tables are made requirements by incorporation within Requirement R4, part 4.1, and therefore are not reference documents. They are created in response to FERC Order 693 and the approved SAR which assigned the SDT to develop a Standard with maximum allowable intervals and minimum maintenance activities.

Comment:	“The MRO’s NERC Standards Review Subcommittee believes the proposed implementation plan for R1 is unreasonably short. It proposes that: “Entities shall be 100% compliant on the first day of the first calendar quarter three months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter six months following Board of Trustees adoption.” We believe the implementation periods should be expanded to twice what was proposed in the implementation plan due to the sheer volume of equipment that will need to meet compliance. Thus, we propose an alternate implementation plan for requirement R1, “Entities shall be 100% compliant on the first day of the first calendar quarter six months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twelve months following Board of Trustees adoption.”

Comment:	1. The definition should clarify whether current and voltage transformers themselves are included. 2. This implementation plan and the one for PRC-005-2 should be consistent.
Response:	Thank you for your comment. 1. These devices are included in the modified definition. This component of the Protection System definition is to generally include this functionality as a part of the Protection System. The detailed applicability of this component within PRC-005-2 is addressed within the Standard.

	2. This comment appears to be addressing the Implementation Plan for the Definition, not for the Standard.

Comment:	The current proposal does not require coordination within the interconnection. 1. The standard should require the PCs within an interconnection to coordinate a UFLS Design with all other PCs within the interconnection and that the PCs should be required to develop a coordinated interconnection wide UFLS Design. As proposed the standard could conceivably result in as many different UFLS plans within WECC as there are Planning Coordinators. Additionally, the proposed standard fails to address UFLS relays which are currently part of the existing program which are owned by the customer. Recognition of customer owned relays is critical to have a successful program. To assure areas are covered the LSE needs to be included in the Applicability section. A third concern is the proposed standard attempts to establish continent wide frequency-time curves and eliminate discrete set points. This approach fails to recognize the unique characteristics of the four individual interconnections. Frequency-time curves do not allow for specific and defined measurements and will leave individual entities defaulting to the lowest common denominator. If frequency-time curves are intended to define the boundaries, the determination of discrete set points would fall into the hands of the PCs leading to disagreements among entities. In addition, to determine the frequency-time curves through stability and dynamic modeling, one must establish discrete set points. Frequency-time curves are reverse engineering and require justification and correlation to the reliability of the interconnections – no such justification has been provided.
Response:	Thank you for your comment. Your comments appear to be directed to the NERC Standard addressing development of UFLS programs. The Protection System Maintenance and Testing SDT is unable to address these comments.

Consideration of Comments on Initial Ballot of "Protection System" Definition

The PRC-005 Standard Drafting Team thanks all those who participated in the initial ballot for the proposed revision to the definition of the term, "Protection System."

All balloters are advised to review the comments and responses in this report as an aid in determining how to participate in the recirculation ballot.

Based on stakeholder comments, the drafting team refined its proposed definition of Protection System as shown below:

> Protective relays which respond to electrical quantities, communication systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays, station dc supply, and control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

Several comments questioned the reason for implementing the definition of Protection System in advance of implementing the proposed modifications to PRC-005-1. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now.

Stakeholder comments indicated that applying the expanded scope of the definition of Protection System would to PRC-005-1 would require more than six months and suggested expanding this to 12 months, and the drafting team made this change to the implementation plan. The team adjusted the implementation plan so that entities will have at least twelve months, rather than the six months originally proposed, to apply the new definition of Protection System to PRC-005-1 – Protection System Maintenance and Testing to Requirement R1 of PRC-005-1. The other parts of the implementation plan remain unchanged.

Both clean and redline versions of the definition and the implementation that show the conforming revisions are posted at the following site:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herbert Schrayshuen, at 609-452-8060 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Comment:	It should clearly state in the definition or elsewhere in the standard that automatic ground switches intended to protect the BES are to be considered interrupting devices. This is stated in the Supplemental Reference but the Supplemental Reference is not part of the standard.
Response:	The definition does not identify individual types of interrupting devices. It is left to Regional BES definitions to determine if these devices, the system components "protected" by these devices, and their initiating Protection Systems are BES elements.
Segment:	1, 6
Organization:	Cleco Power LLC

Comment:	The revised definition to Protection System should include the following exception. "Devices that sense non electrical conditions, such as thermal or transformer sudden pressure relays are not included." For consistence across the standards, see PRC-004, which references System Protection, the same definition should be used.
Response:	The definition has been modified to specify, "Protective relays which respond to electrical quantities".

Comment:	1. The term "station" should either be defined or removed from the definition, as it implies transmission and distribution assets while the term "plant" is used to define generation assets. It would suffice to simply refer to the "DC Supply". 2. As written, the implementation plan only specifies a time frame for entities to update their documentation for PRC-005-1 and PRC-005-2 compliance. The implementation plan also needs to give entities a time frame to address any required changes to their documentation for other standards that use the term "Protection System", including but not limited to NUC-001-2, PER-005-1, PRC-001-1, etc.
Response:	1. The term "station" is used in a generic sense to apply to either "substation" or "generation station"

	facilities. 2. An assessment of the changes to the definition (posted with the first comment period), relative to the entire body of other NERC Standards using this defined term, determined that the changes are consistent with the other existing uses of the definition, and that no other implementation plan considerations were necessary. No comments were received relative to this assessment.

Comment:	The modified definition of Protection System now refers to “functions” rather than “devices.” What are the “functions?” This new term adds confusion without being defined in the standard.
Response:	The “functions” are the accumulated performance of the various portions of the Protection System. This term is used to distinguish “protective functions” from annunciation, signaling, or information.
Segment:	1, 3
Organization:	MidAmerican Energy Co.
Member:	Terry Harbour, Thomas C. Mielnik
Comment:	The following changes should be incorporated in the definition to insure it is used consistently in PRC-005 and any other standards where it appears. The following is a suggested revised definition: “Protection System” is defined as: A system that uses measurements of voltage, current, frequency and/or phase angle to determine anomalies and to trip a portion of the BES to provide protection for the BES and consists of 1) Protective relays for BES elements and, 2) Communications systems necessary for correct BES protection system operations and, 3) Current and voltage sensing devices supplying BES protective relay input and, 4) Station DC supply to BES protection systems excluding battery chargers, and 5) DC control trip paths to the trip coil(s) of the circuit breakers or other interrupting devices for BES

	elements.
Response:	The definition of Protection System establishes “what a Protective System is”, not “what it does”. The application-related suggestions in the comment are best left to individual standards. The SDT, however, did modify the “protective relays” to include only those that respond to electrical quantities. Additionally, constraining relays to “on BES elements” would necessarily exclude UFLS relays, and “trip a portion of the BES” would exclude SPS and UVLS which are on the BES, but which trip non-BES elements. The SDT also disagrees with excluding battery chargers.
Segment:	3, 5, 6

Comment:	LES believes the proposed definition of Protection System as written remains open to interpretation. LES offers the following Protection System definition for the SDT’s consideration: “Protection System” is defined as: A system that uses measurements of voltage, current, frequency and/or phase angle to determine anomalies and trips a portion of the BES and consists of 1) Protective relays, and associated auxiliary relays, that initiate trip signals to trip coils, 2) associated communications channels, 3) current and voltage transformers supplying protective relay inputs, 4) dc station supply, excluding battery chargers, and 5) dc control trip path circuitry to the trip coils of BES connected breakers, or equivalent interrupting device, and lockout relays.
Response:	The definition of Protection System establishes “what a Protective System is”, not “what it does”. The application-related suggestions in the comment are best left to individual standards. The SDT, however, did modify the “protective relays” to include only those that respond to electrical quantities. Additionally, constraining relays to “on BES elements” would necessarily exclude UFLS relays, and “trip a portion of the BES” would exclude SPS and UVLS which are on the BES, but which trip non-BES elements. The SDT also

	disagrees with excluding battery chargers.

Organization:	National Grid
Member:	Saurabh Saksena
Comment:	1. National Grid suggests adding "Protection System Components including" in the beginning. This is because the word "components" has been used extensively throughout the standard and there is no mention of what constitutes a protection system component in the standard. The word "component" does find mention in FAQs, however, it is recommended to mention it in the main standard.

	2. Also, National Grid proposes a change in the proposed definition (changing "voltage and current sensing inputs" to "voltage and current sensing devices providing inputs"). The revised definition should read as follows: Protective System Components including Protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers or other interrupting devices. 3. The time provided for the first phase “at least six months” is too open ended and does not give entities a clear timeline. National Grid suggests 1 year for the first phase. 4. As a result, National Grid suggests phasing out the second phase in stages.
Response:	1. The SDT believes that the suggested text does not add to the definition, and may actually lead to additional problems, such as an implication that the list within the definition is incomplete. 2. The definition has been modified to reflect the proposed change and the “associated circuitry …” has been removed. 3. The implementation plan has been modified to replace “six months” with “twelve months”. 4. The SDT does not understand this comment.
Segment:	10

Comment:	1. The MRO’s NERC Standards Review Subcommittee believes the proposed protection system definition is unclear specifically as it relates to dc station supply. We would like more clarity as to what is included in the dc station supply. 2. We believe battery chargers should not be included in the definition; if the Standard Drafting Team revises the definition we would ask that Table 1 be adjusted, accordingly
Response:	1. The definition addressing “dc supply” was modified. 2. The SDT believes that battery chargers should be included in the definition. Without proper functioning of battery chargers, the battery will be discharged by normal station dc load, and will be unable to perform its function; also, there are some entities which use a charger to provide the dc supply without use of a battery.

Comment:	1. It is still unclear whether relays that respond to mechanical inputs, such as sudden pressure relays, are included in the proposed definition as protective relays. While PRC-005-2 R1 limits the scope of that particular standard to protection systems that sense electrical quantities, it is remains unclear in other standards that use the defined term whether mechanical input protections are included. 2. We suggest that “Protective Relay” also be defined, and that the definition clearly exclude devices that respond to mechanical inputs in line with the NERC interpretation of PRC-005-1 in response to the CMPWG request.
Response:	1. The definition has been modified to specify, “Protective relays which respond to electrical quantities”. 2. “Protective relay” is defined by IEEE and does not have a unique meaning when used in a NERC standard, thus the SDT sees no need to either modify or duplicate that definition.
Segment:	3
Organization:	Central Lincoln PUD
Member:	Steve Alexanderson
Comment:	1. Do you believe the proposed definition of Protection System is ready for ballot? If not, please explain why.

	0 Yes X No Comments: It is still unclear whether relays that respond to mechanical inputs, such as sudden pressure relays, are included in the proposed definition as protective relays. While PRC-005-2 R1 limits the scope of that particular standard to protection systems that sense electrical quantities, it is remains unclear in other standards that use the defined term whether mechanical input protections are included. We suggest that “Protective Relay” also be defined, and that the definition clearly exclude devices that respond to mechanical inputs in line with the NERC interpretation of PRC-005-1 in response to the CMPWG request. 2. Do you agree with the implementation plan for the revised definition of Protection System? The implementation plan has two phases – the first phase gives entities at least six months to update their protection system maintenance and testing program; the second phase starts when the protection system maintenance and testing program has been updated and requires implementation of any additional maintenance and testing associated with the program changes by the end of the first complete maintenance and testing cycle described in the entity’s revised program. If you disagree with this implementation plan, please explain why. X Yes 0 No Comments:
Response:	1. The definition has been modified to specify, “Protective relays which respond to electrical quantities”. 2. Thank you.
Segment:	3
Organization:	Consumers Energy
Member:	David A. Lapinski
Comment:	1. It is unclear whether “voltage and current sensing inputs” include the instrument transformer itself, or does it pertain to only the circuitry and input to the protective relays. 2. It is not clear what is included in the component, “station dc supply” without referring to other documents (the posted Supplementary Reference and/or FAQ) for clarification. The definition should be sufficiently detailed to be clear. 3. If Protection Systems trip via AC methods, are those systems, and the associated control circuitry included in the definition and within the requirements of the Standard as expressed within the Tables?
Response:	1. The definition has been changed for clarity; the SDT intends that the output of these devices, measured at the relay should properly represent the primary quantities.

	2. There are many possible variations to "station dc supply". The definition must be sufficiently general such that variations can be included. 3. The definition has been generalized such that ac tripping is included.
Segment:	1, 3, 5
Organization:	Arizona Public Service Co., APS
Member:	Robert D Smith, Thomas R. Glock, Mel Jensen
Comment:	The change to the definition relative to the voltage and current sensing devices is too prescriptive. Methods of determining the integrity of the voltage and current inputs into the relays to ensure reliability of the devices should be up to the discretion of the utility.
Response:	The definition has been changed for clarity; the SDT intends that the output of these devices, measured at the relay should properly represent the primary quantities.
Segment:	4
Organization:	Consumers Energy

Comment:	From Question 1 on the comment form: The application of this definition to Reliability Standards NUC-001-2, PER-005-1, PRC-001-1, and PRC-004-1 results in confusion as to whether relays with mechanical inputs are included or excluded from this definition. PRC-005-2_R1 contains language limiting its applicability to relays operating on electrical inputs only, but the remaining standards that rely on this definition are not so specific. This being the case, it would make much more sense to clearly define what devices are actually meant in the glossary definition rather than leaving it up to each individual standard to do so.
Response:	The definition has been modified to specify, “Protective relays which respond to electrical quantities”.
Segment:	1, 3
Organization:	Platte River Power Authority
Member:	John C. Collins, Terry L Baker
Comment:	1. Although the applicable relays to which protective relays are outlined in the NERC PRC-005-2 Protection system Maintenance Draft Supplementary Reference dated May 27, 2010, they are not defined in the NERC Glossary of terms. Until it is clearly defined which relays are included inconsistencies will exists from region to region in their audit approaches and which relays they will be looking at. 2. Also, there is still debate why the protective relays would extend to mechanical devices such as the lock-out relay and tripping for trip-free relays. In our system configuration we risk reliability to customer load by testing the lock-out relays which we feel out weights the benefit of testing devices that we see little to no evidence of failure in.
Response:	1. This is properly an issue for the various Regional BES definitions. 2. The definition does not explicitly include these devices, although they are implicitly part of “control circuitry”.
Segment:	3
Organization:	Public Utility District No. 2 of Grant County

Member:	Greg Lange
Comment:	These systems are not always maintained at the component level, i.e. meggering from the relay input test switch through the cable and the CT. This has not closed all the issues around professional judgment (interpretations) that make us nervous when faced with the human element of an audit. We need more specificity to close that gap.
Response:	This issue is properly addressed within the Standard, not within the definition.

Segment:	5
Organization:	Southern Company Generation
Member:	William D Shultz
Comment:	We agree that the definition provides clarity and will enhance the reliability of the Protection Systems to which it is applicable. The negative vote is a result of a belief that the definition's effective date must be coincident with the approval and implementation schedule of PRC-005-2. Since this new definition is directly linked to the proposed revised standard, it would be premature to make this definition effective prior to the effective date of the new standard. If balloted and approved, there is no obligation to or guarantee of any additional maintenance to be performed. PRC-005-2 includes this definition, the maintenance activities, and the intervals that will ensure execution of the maintenance and testing.
Response:	Thank you. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new

	definition to PRC-005-1.

Comment:	The following are the reasons associated with our Negative Ballot. 1. We agree with the definition, however we do not agree with the implementation plan. We believe implementation of the definition needs to coincide with the implementation of Standard PRC-005-2. To do otherwise, will cause entities to address equipment, documentation, work management process, and employee training changes needed for compliance twice within an unreasonably short timeframe. 2. A 12 month minimum timeframe is need to implement this definition 3. We also reserve the right to include selected reasons submitted by other Negative balloters for their Negative Ballot.
Response:	1. Thank you. 2. The Implementation Plan has been modified to allow a 12-month schedule as suggested. However, to agree with the SDT Guidelines established by NERC, "end of the first calendar quarter" was modified to "first day of the first calendar quarter". When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1. 3. Thank you.

Comment:	1. We agree with the definition, however we do not agree with the implementation plan. We believe implementation of the definition needs to coincide with the implementation of Standard PRC-005-2. To do otherwise, will cause entities to address equipment, documentation, work management process, and employee training changes needed for compliance twice within an unreasonably short timeframe. 2. A 12 month minimum timeframe is need to implement this definition
Response:	1. Thank you. 2. The Implementation Plan has been modified to allow a 12-month schedule as suggested. However, to agree with the SDT Guidelines established by NERC, “end of the first calendar quarter” was modified to “first day of the first calendar quarter”. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. Comment:	1. It is unfortunate that the definition did not retain consistency in the terms. As an example, the definition indicates it includes protective relays and communication systems for the correct operation of protective functions. It would have been better to use the term relays instead of the term functions. Now it is unclear what the communication systems are for. 2. The Time Horizons are too narrow for the implementation of the standard as written. The SDT appears to have not accounted for the data analysis associated with performance based systems. The data collection, analysis, and subsequent decisions associated development of a maintenance program and its justification do not occur overnight especially with larger utilities. In addition, this new standard will require complete rewrite of an entities internal maintenance programs. The internal processes associated with these vary based on the

	size of the entity and its organizational structure. Since this standard is so invasive into the internal decisions concerning maintenance, the standard should allow at least 18 months for entities to rewrite their internal maintenance programs to meet the program development requirements and 18 months to train the staff in the new program, incorporate the program into the entities compliance processes, and to implement the new program.
Response:	1. "Functions" was used, as some applications (SPS, for example) may have communications systems that operate other than via protective relays. 2. This comment appears to be focused on the revised Standard, not on the definition.

Comment:	1. As written, is opens up the PRC-005 standard to Technical Feasibility Exceptions because some batteries are not able to accommodate all of the tests proscribed in the draft standard 2. The draft standard would cause NERC to regulate through the standards battery testing, DC circuit testing, etc. on distribution elements with no significant improvement to BES reliability, which is beyond the statutory scope of the standards 3. The standard unreasonably retains the "100% compliance" paradigm for thousands, if not millions of protection

	system components. Will the Standard Introduce Technical Feasibility Exceptions to PRC Standards? a large proportion of the batteries (as high as 50% as reported by some SMEs) are not able to accommodate all of the tests prescribed in the draft standard. Will this necessitate the introduction of TFEs into the process unnecessarily? The Standard Reaches Beyond the Statutory Scope of the Reliability Standards As written, the standard requires testing of batteries, DC control circuits, etc., of distribution level protection components associated with UFLS and UVLS. UFLS and UVLS are different than protection systems used to clear a fault from the BES. An uncleared fault on the BES can have an Adverse Reliability Impact and hence; the focus on making sure the fault is cleared is important and appropriate. However, a UFLs or UVLS event happens after the fault is cleared and is an inexact science of trying to automatically restore supply and demand balance (UFLS) or restore voltages (UVLS) to acceptable levels. If a few UFLS or UVLS relays fail to operate out of potentially thousands of relays with the same function, there is no significant impact to the function of UFLS or UVLS. Hence, there is no corresponding need to focus on every little aspect of the UFLS or UVLS systems. Therefore, the only component of UFLS or UVLS that ought to be focused on in the new PRF-005 standard is the UFLS or UVLS relay itself and not distribution class equipment such as batteries, DC control circuitry, etc., and these latter ought to be removed from the standard. In addition, most distribution circuit are radial without substation arrangements that would allow functional testing without putting customers out of service while the testing was underway, or at least without momentary outages while customers were switched from one circuit to another. Therefore, as written, we would be sacrificing customer service for a negligible impact on BES reliability. Perfection is Not A Realistic Goal The standard allows no mistakes. Even the famous six sigma quality management program allows for defects and failures (i.e., six sigma is six standard deviations, which means that statistically, there are events that fall outside of six standard deviations). PRC-005 has been drafted such that any failure is a violation, e.g., 1 day late on a single relay test of tens of thousands of relays is a violation. That is not in alignment with worldwide accepted quality management practices (and also makes audits very painful because statistical, random sampling should be the mode of audit, not 100% review as is currently being done in many instances). FMPA suggests considering statistically based performance metrics as opposed to an unrealistic performance target that does not allow for any failure ever. Due to the shear volume of relays, with 100% performance required, if the standards remain this way, PRC-005 will likely be in the top ten most violated standards for the forever. There is a fundamental flaw in thinking about reliability of the BES. We are really not trying to eliminate the risk of a widespread blackout, we are trying to reduce the risk of a widespread blackout. We plan and operate the system to single and credible double contingencies and to finite operating and planning reserves. To eliminate the risk, we would need to plan and operate to an infinite number of contingencies, and have an infinite reserve margin, which is infeasible. Therefore, by definition, there is a finite risk of a widespread blackout that we are trying to reduce,

	not eliminate, and, by definition, by planning and operating to single and credible double contingencies and finite operating and planning reserves, we are actually defining the level of risk from a statistical basis we are willing to take. With that in mind, it does not make sense to require 100% compliance to avoid a smaller risk (relays) when we are planning to a specified level of risk with more major risk factors (single and credible double contingencies and finite planning and operating reserves).

Comment:	We Energies does not agree to the implementation plan proposed. While it makes common sense to proceed with R1 prior to proceeding with implementing R2, R3, and R4, the timeline to be compliant for R1 is too short. It will take a considerable amount of resources to migrate the maintenance plan from today's standard to the new standard in phase one. ATC recommends that time to develop and update the revised program be increased to at least one year followed by a transition time for the entity to collect all the necessary field data for the protection system within its first full cycle of testing. (In ATC's case would be 6 years) To address phase two, We Energies believes human and technological resources will be overburdened to implement this revised standard as written. The transition to implementing the new program will take another full testing cycle once the program has been updated. Increased documentation and obtaining additional resources to accomplish this will be challenging. Implementation of PRC-005-2 will impact We Energies in the following manner: a. Increase costs: double existing maintenance costs. b. Since there will be a doubling of human interaction (or more), it is expected that failures due to human error will increase, possibly proportionately. c. Breaker maintenance may need to be aligned with protection scheme testing, which will always contain elements that are include in the non-monitored table for 6 yr testing. d. We Energies is developing standards for redundant bus and transformer protection schemes. This would allow We Energies to test the protection packages without taking the equipment out of service. Further if one system fails, there is full redundancy available. With the current version of PRC-005-2, We Energies would need to take an outage to test the protection schemes for a transformer or a bus, there is not an incentive to install redundant schemes. We Energies is working with a condition based breaker maintenance program. This program's value would be greatly diminished under PRC-005-2 as currently written. Consideration also needs to be given for other NERC standards expected to be passed and in the implementation stage at the same time, such as the CIP standards.

Comment:	Station DC supply testing was set at three months. A six month time based testing interval is reasonable. Maximum maintenance interval for a lead-acid vented battery is liste at six calendar years. This type of test

	reduces battery life. A 10 to 12 year interval is reasonable. As written this rule would require a TFE that should be administratively unnecessary. Additional clarification is needed in: Control and trip circuits associated with UVLS and UFLS do not require tripping of the breakers but all other protection systems require tripping. Please clarify. Digital relays have electromagnetic output relays - are they categorized as electromechanical or solid state? There needs to be reasonable flexibility based on industry experience in allowing less than 100% perfection in the testing of relays, etc.

Comment:	The requirement for taking intracell readings is not possible for all batteries. Some minor rewording would resolve this issue and make it applicable to those batteries that have internal cell-to-cell straps. I would recommend changing the minimum requirement to take intracell resistance readings from the battery terminals, since identifying the particular cell that is going bad is of little use. I imagine all utilities replace an entire jar, not individual cells. The draft standard would cause NERC to regulate, through the standards battery testing, DC circuit testing, etc. on distribution elements with no significant improvement to BES reliability, which is beyond the statutary scope of the standards The standard unreasonably retains the "100% compliance" paradigm for thousands, if not millions of protection system components. This becomes an investigation, not an audit. There is no way an audit team will have the time to arrive at 100% compliance with a large entity.

Comment:	SRP believes the requirements of the Standard are confusing and may be problematic in determining compliance. We also believe the required functional testing of the breaker trip coil may potentially increase maintenance outages of circuit breakers. In most cases, circuit breaker maintenance outages can be coordinated such that Protection System maintenance and testing can be done simultaneously. However, in some cases this may not be possible. Outages of any BES facility whether planned or unplanned can impact system reliability. SRP suggests that trip coil monitoring devices be included as an acceptable means of ensuring the trip coil is functioning properly. This will help to avoid unnecessary outages.

Organization:	PPL Electric Utilities Corp.
Member:	Brenda L Truhe
Comment:	PPL EU is voting negative because Rqmt 1.1 "Identify all Protection System components" is too broad and must be clarified and the definition of Protective Relays is not limited to only those devices that use electrical quantities as inputs (exclude pressure, temperature, gas, etc).
Segment:	1
Organization:	Pacific Gas and Electric Company
Member:	Chifong L. Thomas
Comment:	We are concerned over R1.1, where all components must be identified, without a definition for the word component or the granularity specified. While the FAQ gives a definition, and allows for entity latitude in determining the granularity, the FAQ is not part of the standard. We are concerned whether identification is required for every individual component, such as each auxiliary relay, or is it sufficient that the auxiliary relays are included within the scheme that is being tested and documented. Do the auxiliary relays need to be documented within the maintenance database and/or on the actual test reports of schemes being tested? We suggest that the FAQ definitions be included within the standard.

Consideration of Comments on Non-binding Poll of VRFs and VSLs associated with PRC-005-2 – Protection System Maintenance

The PRC-005 Standard Drafting Team thanks all those who participated in non-binding poll for the VRFs and VSLs associated with PRC-005-2. The initial non-binding poll was conducted from July 8 through July 17, 2010 and achieved a quorum with 85.96 % of the ballot pool members returning an opinion, and with 32.29 % of those indicating support for the proposed VRFs and VSLs.

Many commenters proposed that the VSLs allow for some amount of non-compliance with the Standard before incurring a violation. NERC's guidelines for VSLs do not allow some level of non-performance without being in violation. The SDT did, however, modify the VSLs for Requirements R1 and R4 to provide gradated VSLs.

Some commenters suggested the SDT re-evaluate the VRF assignments. The SDT reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and modified the Standard to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High. Some commenters made comments that appeared to be related to the technical content of the Standard, not to the VRFs or VSLs and these comments were addressed in the report containing responses to comments on the standard. All comments submitted have been publicly posted on the following web page:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herbert Schrayshuen, at 609-452-8060 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

Segment:	3, 4, 5
Organization:	Cowlitz County PUD
Member:	Russell A Noble, Rick Syring, Bob Essex
Comment:	Cowlitz does not understand a High VRF designation for requirement R1; this should be a Low or Medium designation. R1 is merely covering a maintenance program, not the actual maintenance. Actual missed maintenance of components (requirement R4) should have the Medium or High VRF. This Standard is very descriptive of minimum maintenance intervals on each "component;" thus, it is possible to have maintenance documentation that is in full compliance once the Program is built around it. It should never be a case where an entity can receive a higher VRF over missing documentation of a process, and then a lower VRF over missing documentation of the implementation of the process.
Response:	The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High.
Segment:	1
Organization:	United Illuminating Co.
Member:	Jonathan Appelbaum
Comment:	The VRF for R1 should be Low. It is administrative to create an inventory list. If R1 failed to be executed but the other requirements wee executed fully then the BES would be properly secured. Compare this against the scenario of performing R1 but failing to perform the other tasks; in which case the BES is at risk. UI recognizes that the SDT considers the inventory as the foundation of the PSMP but it is not the element of the PSMP that provides for the level of reliability sought. R1 should be VRF Low and R2 thru R4 VRF is Medium. UI agrees with the Time Horizon.
Response:	The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High.

Segment:	1, 3, 4, 5, 6
Organization:	FirstEnergy Energy Delivery, FirstEnergy Solutions, Ohio Edison Company, FirstEnergy Solutions, FirstEnergy Solutions
Member:	Robert Martinko, Kevin Querry, Douglas Hohlbaugh, Kenneth Dresner, Mark S Travaglianti
Comment:	FirstEnergy appreciates the hard work of the drafting team, but unfortunately we must cast a Negative vote for the VRF for Requirement R1. Although we agree that Requirement 1 is important because it establishes a sound PSMP, a HIGH VRF assignment is not appropriate and it should be changed to LOWER. By definition, a requirement with a LOWER VRF is administrative in nature, and documentation of a program is administrative. Assigning a LOWER VRF to R1 is more logical since R4, which is the requirement to implement the PSMP, is assigned a MEDIUM VRF because, if violated, it could directly affect the electrical state or the capability of the bulk electric system.
Response:	The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High.
Segment:	1
Organization:	Ameren Services
Member:	Kirit S. Shah
Comment:	The Lower VSL for all Requirements should begin above 1% of the components.
Response:	The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation.
Segment:	5
Organization:	Constellation Power Source Generation, Inc.
Member:	Amir Y Hammad
Comment:	In general, the VSLs are completely biased against small generating facilities that may have only 20 or 30 components to their protective system. If a facility with only 30 components were to fail to identify 2 components, then that would automatically fall under a moderate VSL. This is true for R1 and R4. A suggestion would be to eliminate the percentage of components and instead focus on what the violation is. For example, for R1, a lower VSL could state “the entity’s PSMP includes all of the ‘types’ of components included in the definition of ‘Protection System’, but failed to specify whether a component is being addressed

	by time-based, condition-based, or performance-based maintenance.
Response:	The SDT believes the stepped VSLs are not biased against small entities.
Segment:	5
Organization:	Liberty Electric Power LLC
Member:	Daniel Duff
Comment:	Voting no due to a no vote on the standard, as well as a disagreement with the percentage concept. Smaller entities will have a higher violation level for the same offense due to fewer chances for a violation.
Response:	The SDT believes the stepped VSLs are not biased against small entities.
Segment:	5, 6
Organization:	Tennessee Valley Authority
Member:	George T. Ballew, Marjorie S. Parsons
Comment:	The reason for the no vote on the Non-Binding Poll for VRFs and VSLs is the Violation Severity Level Table listing for Requirement R4 lists the following under "Severe VSL". "Entity has failed to initiate resolution of maintenance-correctable issues" The threshold for a Severe Violation in this case is too broad and too subjective. The threshold needs to be clearly defined with low, medium, and high criteria. This feedback has been added to the NERC Standards Under Development Comment webpage.
Response:	The VSL for Requirement R4 has been modified to provide a stepped VSL for initiation of resolution of maintenance correctable issues.
Segment:	1
Organization:	Duke Energy Carolina
Member:	Douglas E. Hils
Comment:	We appreciate the work of the team however we do not agree with some of the text proposed. The VSLs for PRC-005-2 requirements R1, R2 and R4 have significantly tighter percentages than the corresponding requirements in PRC-005-1. We believe that the Lower VSL should be up to 10%, the Moderate VSL should be 10%-15%, the High VSL should be 15% to 20%, and the Severe VSL should be greater than 20%, which is still a lower percentage than

	the 25% Lower VSL currently in PRC-005-1.
Response:	The percentages for the stepped VSLs were established in accordance with the NERC VSL Guidelines which were in turn established pursuant to the FERC VSL Order. The current approved PRC-005-1 preceded these guidelines, and therefore is not in accordance with them.

Comment:	The intervals in the standard are based on the weighted average practice of entities surveyed. The weighted average practice was the result of a requirement to have a documented program. The intervals did not have demonstrated relationship to reliability of the BES. This nullifies the requirements and subsequent VSL's. 1. The VSL's use terms that are not tied back to a requirement and appear to be based on the concept that every component will cause an impact on the BES. The VSL's use the term "countable event" to score the VSL; however, there is no requirement associated with the number of "countable events". 2. The VSL's should allow for minor gaps in maintenance documentation where there is no impact to the BES if the component failed.
Response:	1. The SDT disagrees that the VSLs are not tied back to a requirement. R3 refers to Attachment A for the criteria for a performance based program, which establishes criteria for the percentage of countable events allowed for the components in any specific designated segment. 2. “Minor gaps in maintenance documentation” would seem to be within the description of a Lower VSL; the NERC criteria for VSLs do not currently permit them to allow some “gaps” without being in violation. The VSL for Requirement R4 has been modified to provide a stepped VSL for initiation of resolution of maintenance correctable issues.

Comment:	1. As the current requirements are written in R1 of PRC-005-2 Draft, we disagree with the terms identify all Protection System components. We recommend a less prescriptive requirement as listed below. R1.1 Identify BES substations or facilities containing Protection Systems.

	R1.2 Identify whether Protection Systems per substation or facilities are addressed through time-based, condition-based, performance based or a combination based etc. R1.3 For each substation/facility with Protection Systems, include all maintenance activities etc. 2. The VRF for R1 ranking should be lower or no greater than R2, R3, and R4. The task of identifying Protection System components has very little to do with increasing reliability of the BES. The implementation of the PSMP most likely will cover all the specific functions of Protection System components although the entity failed to identify all PS components. 3. We recommend the above language changes and agree the requirement adds some value but not a high-risk value to the BES. After correcting the language we feel that a requirement of 100% maintenance on 100% of all components as listed on page 6 of the standard for the VSLs leaves no room for error for systems designed with contingences. The violations should start for more than a level of 5% not identified, not maintained, etc.
Response:	1. This appears to be a comment related to the standard content, not the VRFs and VSLs. 2. The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High. 3. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation.

Comment:	National Grid does not support the VSL criteria based on "total number of components". Calculating total number of components will be hugely costly and does not enhance any reliability. It will also take away the much needed resources required for maintenance.
Response:	The SDT believes establishing multiple levels within the VSL is preferable to assigning only a Severe VSL; consequently, a method of measuring relative performance must exist, and determining the quantity of components is a necessity.

Member:	R Scott S. Barfield-McGinnis, Guy Andrews

Comment:	1. Do not agree with the 3 calendar months interval and suggest using quarterly. Both terms require a minimum of four inspections per year have proven to be successful, but the term “quarterly” provides a bit more flexibility than the term “3 calendar months”. Given a 3 month maximum interval an entity would need to schedule these tasks every 2 months. As the current requirements are written in R1 of PRC-005-2 Draft, we disagree with the terms identify all Protection System components. We recommend a less prescriptive requirement as listed below. -R1.1 Identify BES substations or facilities containing Protection Systems. -R1.2 Identify whether Protection Systems per substation or facilities are addressed through time-based, condition-based, performance based or a combination based etc. -R1.3 For each substation/facility with Protection Systems include all maintenance activities etc. 2. The VRF for R1 ranking should be lower or no greater than R2, R3, and R4. The task of identifying Protection System components has very little to do with increasing reliability of the BES. The implementation of the PSMP most likely will cover all the specific functions of Protection System components although the entity failed to identify all PS components. We recommend the above language changes and agree the requirement adds some value but not a high-risk value to the BES. 2. After correcting the language we feel that a requirement of 100% maintenance on 100% of all components as listed on page 6 of the standard for the VSLs leaves no room for error for systems designed with contingences. 3. The violations should start for more than a level of 5% not identified, not maintained, etc. Listing each individual Protection System component as current draft is onerous and impedes any interpretation of application with very little value. 4. The standard as written will require a great deal of effort by the utilities to maintain 100% compliance as listed. The concern is the power system design allows for some contingencies but the standard allows for no errors. Failing to complete 1% of the maintenance by 1 day infers an entity is out of compliance or in violation. 5. The violations should start for more than a level of 5% not identified, or not maintained. We feel the minor changes of wording as described in R1.1 – R1.3 as listed above will go a long way in removing the concerns of the standard. We feel the intent of the standard is sound and request minor changes to facilitate an interpretable standard that sensibly mitigates problems with the BES. As the standard written, the

	interpretation seems to create a stringent environment with undue compliance requirements. 6. Lastly, the SDT should attempt to embrace Gerry Cauley's vision of "results-based standards" and clearly identify the "risk mitigation objectives, reliability result or outcome" of the revised requirements and allow each entity to meet the outcome and mitigate the risk without writing in such a prescriptive manner which is not preferred. The prescriptive details currently proposed in the standard could then be captured in a reference document.
Response:	1. This comment appears be related to the technical content of the standard and not on the VRFs or VSLs. 2. The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High. 3. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. 4. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. 5. The SDT believes establishing multiple levels within the VSL is preferable to assigning only a Severe VSL; consequently, a method of measuring relative performance must exist, and determining the quantity of components is a necessity. 6. This comment appears to be related to the standard itself, not to the VRFs or VSLs.

Comment:	Entergy provides the following reasons for our Negative Ballot. Entergy reserves the right, after review of all the submitted ballots, to join with other balloters, whether positive or negative ballots, where any reasons included in their ballot that may be applicable to or otherwise impact Entergy as related to this ballot. 1. The VSLs for R1 is “Failure to specify whether a component is being addressed by time-based, condition-based, or performance-based maintenance” by itself is a documentation issue and not an equipment maintenance issue. We recommend this warrants only a Lower VSL, especially when one of the required components can only be time based. 2. We also recommend the VSLs for R4 be revised to be stepped from Lower to Severe for “Entity has failed to initiate resolution of maintenance-correctable issues”. While we understand the importance of addressing a correctable issue, it seems like there should be some allowance for an isolated unintentional failure to address a correctable issue. If possible, consider the potential impact to the system. For example, a failure to address a pilot scheme correctable issue for an entity that only employs pilot schemes for system stability applications should not necessarily have the same VSL consequence as an entity which employs pilot schemes everywhere on their system as a standard practice.
Response:	1. This portion of the VSL for Requirement R1 has been modified to provide a stepped VSL relating to the number of Component Types that are not addressed by time-based, condition-based, or performance-based maintenance. 2. The VSL for Requirement R4 has been modified to provide a stepped VSL for initiation of resolution of maintenance correctable issues.

Comment:	There is not enough clarity on whether a Distribution Provider (DP) will be able to clearly identify which protection system components it does own and needs to maintain. Many DPs own and/or operate equipment identified in the existing or proposed definition. However, not all such equipment translates into a transmission Protection System. The definition needs clarification on when such equipment is a part of the transmission protection system. Also, the time provided for the first phase "at least six months" is too open ended and does not provide entities with a clear timeline. It is suggested that one year is appropriate for the first phase phasing out the second year in stages.
Response:	This appears to be a comment on the technical content of the standard, definition, and Implementation Plan,

	not on the VRFs or VSLs.

The definition needs clarification on when such equipment is a part of the transmission protection system. Also, the time provided for the first phase "at least six months" is too open ended and does not provide entities with a clear timeline. It is suggested that one year is appropriate for the first phase phasing out the second year in stages. Regarding battery visuals, the suggestion for consideration is it should be changed from 3 months to 6 months. Electrolyte levels of today's lead-calcium batteries are relatively stable for a 6 month period compared to lead-antimony batteries used in the past. The Implementation plan is too short - In many instances it will be impossible to meet, especially if entities have to create, purchase and adopt new databases to track maintenance activities. Often new procedures will have to be written and additional resources justified and hired. It would be more acceptable if a staged approached was taken similar to the DME Standard. Accounting for every component of a protection system will be an enormous overhead and will take away resources from actually doing maintenance. Emphasis should be on systems and not individual components.The Standard does not provide a grace period if an entity is unable to meet the maintenance requirement for extenuating circumstances. For example if an entity has to divert maintenance resources to storm restoration following a major event, slack built into a maintenance program can be eaten up and put the maintenance over the prescribed period. Provision should be made for a mitigation plan to get back on track. We do not believe the reliability of the Bulk Electric System will be compromised if an entities' maintenance program slips by a few months due to extreme contingencies, especially if it is brought back on track within a short time frame.

Comment:	FMPA recommends a negative vote on PRC-005-2, Project 2007-17, for three significant reasons 1. As written, it opens up the PRC-005 standard to Technical Feasibility Exceptions because some batteries are not able to accommodate all of the tests proscribed in the draft standard as explained by Steve Alexanderson in a prior e-mail to the ballot pool. The draft standard would cause NERC to regulate through the standards battery testing, DC circuit testing, etc. on distribution elements with no significant improvement to BES reliability, which is beyond the statutory scope of the standards 2. The standard unreasonably retains the "100% compliance" paradigm for thousands, if not millions of protection system components. Will the Standard Introduce Technical Feasibility Exceptions to PRC Standards? As described by Steve Alexanderson in a prior e-mail to the ballot pool, a large proportion of the batteries (as high as 50% as reported by some SMEs) are not able to accommodate all of the tests prescribed in the draft standard. Will this necessitate the introduction of TFEs into the process unnecessarily? The Standard Reaches Beyond the Statutory Scope of the Reliability Standards As written, the standard requires testing of batteries, DC control circuits, etc., of distribution level protection components associated with UFLS and UVLS. UFLS and UVLS are different than protection systems used to clear a fault from the BES. An uncleared fault on the BES can have an Adverse Reliability Impact and hence; the focus on making sure the fault is cleared is important and appropriate. However, a UFLs or UVLS event happens after the fault is cleared and is an inexact science of trying to automatically restore supply and demand balance (UFLS) or restore voltages (UVLS) to acceptable levels. If a few UFLS or UVLS relays fail to operate out of potentially thousands of relays with the same function, there is no significant impact to the function of UFLS or UVLS. Hence, there is no corresponding need to focus on every little aspect of the UFLS or UVLS systems. Therefore, the only component of UFLS or UVLS that ought to be focused on in the new PRF-005 standard is the UFLS or UVLS relay itself and not distribution class equipment such as batteries, DC control circuitry, etc., and these latter ought to be removed from the standard. In addition, most distribution circuit are radial without substation arrangements that would allow functional testing without putting customers out of service while the testing was underway, or at least without momentary outages while customers were switched from one circuit to another. Therefore, as written, we would be sacrificing customer service for a negligible impact on BES reliability. Perfection is Not A Realistic Goal The standard allows no mistakes. Even the famous six sigma quality management program allows for defects and failures (i.e., six sigma is six standard deviations, which means that statistically, there are events that fall outside of six standard deviations). PRC-005 has been drafted such that any failure is a violation, e.g., 1 day late on a single relay test of tens of thousands of relays is a violation. That is not in alignment with worldwide accepted quality management practices (and also makes audits very painful because statistical, random sampling should be the mode of audit, not 100% review as is currently being done in many instances). FMPA suggests

	considering statistically based performance metrics as opposed to an unrealistic performance target that does not allow for any failure ever. Due to the shear volume of relays, with 100% performance required, if the standards remain this way, PRC-005 will likely be in the top ten most violated standards for the forever. There is a fundamental flaw in thinking about reliability of the BES. We are really not trying to eliminate the risk of a widespread blackout, we are trying to reduce the risk of a widespread blackout. We plan and operate the system to single and credible double contingencies and to finite operating and planning reserves. To eliminate the risk, we would need to plan and operate to an infinite number of contingencies, and have an infinite reserve margin, which is infeasible. Therefore, by definition, there is a finite risk of a widespread blackout that we are trying to reduce, not eliminate, and, by definition, by planning and operating to single and credible double contingencies and finite operating and planning reserves, we are actually defining the level of risk from a statistical basis we are willing to take. With that in mind, it does not make sense to require 100% compliance to avoid a smaller risk (relays) when we are planning to a specified level of risk with more major risk factors (single and credible double contingencies and finite planning and operating reserves).
Response:	1. This comment appears to be related to the technical content of the Standard, not on the VRFs or VSLs. 2. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. Much of this comment appears to be related to the technical content of the standard, not on the VRFs or VSLs.

Comment:	1. If multiple redundant Protection System components, with associated parallel tripping paths, are provided, Table 1a, 1b, and 1c require that each parallel path be maintained, and that the maintenance be documented. Often, these multiple schemes are provided not to meet specific reliability-related requirements, but instead to provide operating flexibility. Testing these likely will require outages, and those outages may result in decreased reliability. Further, the documentation related to maintenance of all paths will be very cumbersome, and will lead to increased compliance exposure simply by its volume. This may perversely lead to entities NOT installing the redundant schemes, resulting in decreased reliability. 2. Many of the activities described in the Tables are not, by themselves, clear. The standard should include sufficient detail such that entities are clear as to what must be done for compliance, rather that relying on supplementary documents for this information. For example, it's not clear, in Table 1a (Station DC Supply), what is meant by, "Verify that the dc supply can perform as designed when the ac power from the grid is not present." Similarly, it isn't clear from the general description within the Tables that components possessing different monitoring attributes within a single scheme, may be distinguished such that differing relevant tables can be used for the separate components. 3. In Table 1a, Station DC Supply, one of two optional activities is to "Verify that the station battery can

	perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. Battery assemblies supplied by some manufacturers have the connections made internally, making this option unavailable. Experience with ASME standards show that NERC and SDT members may be jointly and separately liable for litigation by specifying methods that either prefer or prohibit use of certain technologies. 4. Two of the four Maintenance Activities that begin with “Perform a complete functional trip …“ conclude with “… does not require actual tripping of circuit breakers or other interrupting devices. Do the other two such activities therefore require tripping of circuit breakers or other interrupting devices? 5. Performance of the minimum activities specified within Table 1a for legacy systems, particularly regarding control circuits, will require considerable disconnection and reconnection of portions of the circuits. Such activities will likely cause far more problems on restoration-to-service than they will locate and correct. We suggest that the SDT reconsider these activities with regard for this concern. 5. We do not agree that Footnotes within the Standard are an appropriate method of providing information that is important to the application of the Standard. Important information should be provided within the standard text. 6. As for the definition, it is unclear whether “voltage and current sensing inputs” include the instrument transformer itself, or does it pertain to only the circuitry and input to the protective relays. 7. As for the definition, it is not clear what is included in the component, “station dc supply” without referring to other documents (the posted Supplementary Reference and/or FAQ) for clarification. The definition should be sufficiently detailed to be clear. 8. If Protection Systems trip via AC methods, are those systems, and the associated control circuitry included in the definition and within the requirements of the Standard as expressed within the Tables?

Comment:	SRP believes the requirements of the Standard are confusing and may be problematic in determining compliance. We also believe the required functional testing of the breaker trip coil may potentially increase maintenance outages of circuit breakers. In most cases, circuit breaker maintenance outages can be coordinated such that Protection System maintenance and testing can be done simultaneously. However, in some cases this may not be possible. Outages of any BES facility whether planned or unplanned can impact system reliability. SRP suggests that trip coil monitoring devices be included as an acceptable means of ensuring the trip coil is functioning properly. This will help to avoid unnecessary outages.

Comment:	1. As written, it opens up the PRC-005 standard to Technical Feasibility Exceptions because some batteries are not able to accommodate all of the tests proscribed in the draft standard. The draft standard would cause NERC to regulate through the standards battery testing, DC circuit testing, etc. on distribution elements with no significant improvement to BES reliability, which is beyond the statutory scope of the standards 2. The standard unreasonably retains the "100% compliance" paradigm for thousands, if not millions of protection system components.
Response:	1. This comment appears to be related to the technical content of the Standard, not to the VRFs or VSLs. 2. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. Much of this comment appears to be related to the technical content of the Standard, not on the VRFs or VSLs.

Comment:	PPL EU is voting negative because Requirement 1.1 "Identify all Protection System components" is too broad and must be clarified and the definition of Protective Relays is not limited to only those devices that use electrical quantities as inputs (exclude pressure, temperature, gas, etc).
Response:	This comment appears to be related to the technical content of the Standard, not to the VRFs or VSLs.

Consideration of Comments on Proposed Definition of Protection System for Project 2007-17

The Protection System Maintenance and Testing Standard Drafting Team thanks all commenters who submitted comments on the draft definition of "Protection System." This document was posted for a special 35-day public comment period from June 11, 2010 through July 16, 2010. Stakeholders were asked to provide feedback on the proposed definition through a special Electronic Comment Form. There were 50 sets of comments, including comments from more than 110 different people from over 55 companies representing 8 of the 10 Industry Segments as shown in the table on the following pages.

Based on stakeholder comments, the drafting team refined its proposed definition of Protection System as shown below:

> Protective relays , which respond to electrical quantities, communication systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays, station dc supply, and control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

Several comments questioned the reason for implementing the definition of Protection System in advance of implementing the proposed modifications to PRC-005-1. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now.

Stakeholder comments indicated that applying the expanded scope of the definition of Protection System would to PRC-005-1 would require more than six months and suggested expanding this to 12 months, and the drafting team made this change to the implementation plan. The team adjusted the implementation plan so that entities will have at least twelve months, rather than the six months originally proposed, to apply the new definition of Protection System to PRC-005-1 – Protection System Maintenance and Testing to Requirement R1 of PRC-005-1. The other parts of the implementation plan remain unchanged.

All work of the drafting team has been posted at the following site:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herbert Schrayshuen, at 609-452-8060 or at Herb.Schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

---

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

1. Do you believe the proposed definition of Protection System is ready for ballot? If not, please explain why.

Summary Consideration: Almost half of the commenters felt that the definition itself was not ready for ballot.

Many commenters wanted more clarity regarding the portion of the definition addressing "voltage and current sensing inputs to protective relays ... ". The SDT inserted the words "devices providing" into the phrase to clarify that instrument transformers are included in the definition. This portion of the definition now reads:

- Voltage and current sensing devices providing inputs to protective relays,

Many commenters also suggested that the definition should limit the protective relays "to those using electrical quantities", rather than addressing this subject as a footnote in the standard. The SDT incorporated this suggestion; this portion of the definition now reads:

- "Protective relays which respond to electrical quantities".

The SDT also removed the phrase "from the station dc supply" from the "control circuitry" portion of the definition.

Some commenters suggested that "protective relays" be defined; the SDT chose not to do this as IEEE already defines this term. Many commenters also offered comments on the standard itself. These comments are being addressed in the comment forms for the standard.

The revised definition is:

Protection System:

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply, and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

Several commenters indicated that the definition should not apply to PRC-005-1. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.

Organization	Yes or No	Question 1 Comment
GDS Associates	No	1. The inserted wording "and associated circuitry from the voltage and current sensing devices" implies that the maintenance program will include the verification, monitoring, etc. of the wiring from the voltage/current sensing devices which requirement will be a bit excessive under current presentation of the standard. See comment on the standard as well. 2. SDT's additional wording such as "from the station DC supply through the trip coil(s) of the circuit breakers or other interrupting devices" can be a bit of an issue as the coils could be good at time of verification and testing, but can fail right after or due to the testing. We recommend to change the Protection System definition to read "up to the trip coils(s)" instead the word "through"
Response: Thank you for your comments. **1. The definition has been modified to say, "voltage and current sensing devices providing inputs to protective relays".** **2. The SDT disagrees, and asserts that the trip coil(s) must be included within the Protection System. The observation that the element may be good at the time of verification and testing, but fail immediately thereafter, is true of any device that is not monitored continuously for proper operating function.**		
Grant County PUD	No	1) We note that the definition of a "Protection System" has been expanded to include the trip coils and what used to be confined to batteries has now been expanded to "station DC supply." "Trip coils" is an improvement. Inasmuch as the mark-up changing "DC" to "dc" is intended to communicate a more general term as opposed to a strict definition, it leaves room for differing opinions among auditors as to what all should be included. We

Organization	Yes or No	Question 1 Comment
		support the change to exclude battery chargers since the rationale for their inclusion was never clear. The battery itself will be, without exception, the "first responder" to provide DC power to a Protection System. However, battery chargers have not been excluded under the FAQs. 2) The SPCTF's effort to define applicability in terms of "Facilities" is confusing. Additionally, it is unclear how the terms "component," "element" and "Facility" are intended to relate to one another. An assumption may be that one or more components (which are physical assets) can comprise an "element," one or more of which can be associated with an identifiable function, aligning with the five Protection System Equipment Categories, found in SPCTF's "PROTECTION SYSTEM MAINTENANCE-A Technical Reference, dated Sept. 13, 2007, and that "Facility" is as used in 4.2.1 of the Standard Development Roadmap, dated May 27, 2010. Please provide guidance on the terms relate to one another. 3) The structure of the proposed standard is less clear than the existing standard PRC-005-1 because of the potential for ambiguity between the definition of Protection System and how the term "Facilities" is applied. A suggested resolution would be to revise the definition of Protection System to resolve this ambiguity or to delete reference to 86 lockouts and auxiliary relays in the description of "Facilities." If the 86 lockout relays are to be included, they should be added as part of the DC Control Circuitry "element" (as found in the NERC Glossary) of the circuit that energizes the 86 relay, thus placing it within the definition of a "Protection System."-once-and therefore in a manner that would require only one scheduled maintenance to be performed if the testing schemes are properly set up. We do agree, however, that sudden pressure relays, reclosing relays, and other non fault detecting relays such as loss of cooling relays should not be referenced as part of the "dc control circuitry" Element.

Response: Thank you for your comments.

1. A recent Interpretation request, referring to the currently approved definition specifying "station batteries", excluded

Organization	Yes or No	Question 1 Comment
battery chargers. The change to "station dc supply" is intended to expand the definition to include all essential elements including battery chargers; without proper functioning of battery chargers, the battery will be discharged by normal station dc load, and will be unable to perform its function; also, there are some entities which use a charger to provide the dc supply without use of a battery. Use of "dc" rather than "DC" reflects the IEEE style guide for this term. The FAQ intentionally does not exclude battery chargers as the SDT intend to include them within PRC-005-2. **2. This comment does not appear to apply to the definition, but instead to the draft Standard itself.** **3. The SDT contends that "dc control circuitry" includes elements such as lockout relays and auxiliary relays.**		
Consumers Energy	No	1. It is unclear whether "voltage and current sensing inputs" include the instrument transformer itself, or does it pertain to only the circuitry and input to the protective relays? 2. It is not clear what is included in the component, "station dc supply" without referring to other documents (the posted Supplementary Reference and/or FAQ) for clarification. The definition should be sufficiently detailed to be clear. 3. If Protection Systems trip via AC methods, are those systems, and the associated control circuitry included?
Response: Thank you for your comments. **1. The SDT has modified the definition for clarity; the SDT intends that the output of these devices, measured at the relay, properly represents the primary quantities.** **2. There are many possible variations to "station dc supply"; it seems impossible to reflect all variations in the definition. The definition must be sufficiently general such that variations can be included.** **3. The definition has been generalized such that ac tripping is included.**		
Public Service Enterprise Group ("PSEG Companies")	No	Based on review of ballot pool comments there are still too many questions that should be resolved prior to submittal for ballot. It is suggested that a specific reference to the supplementary reference document figures 1 & 2 and the legend be added. That would

Organization	Yes or No	Question 1 Comment
		further define the protection system components and scope boundary.
Response: Thank you for your comments. The SDT has revised the definition to make it more clear as a stand-alone product.		
CenterPoint Energy	No	CenterPoint Energy believes the proposed definition of “Protection System” is technically incorrect. The present definition does not include trip coils of interrupting devices, such as circuit breakers; and correctly so, as trip coils are components of the interrupting device. A Protection System has correctly performed its function if it provides tripping voltage up to the circuit breaker trip coil. From that point, the circuit breaker can fail to timely interrupt fault current due to several factors, such as a binding mechanism that affects breaker clearing time, a broken pull rod, a bad insulating medium, or bad trip coils. Local breaker failure protection, or remote backup protection, is installed to address the various possible causes of circuit breaker failure. For correctness, the definition of “Protection System” should be “Protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from the station dc supply UP TO THE TERMINALS OF the trip coil(s) of the circuit breakers or other interrupting devices.”
Response: Thank you for your comments. The SDT disagrees, and asserts that the trip coil(s) must be included within the Protection System.		
Constellation Power Generation	No	Constellation believes that this definition is to verbose, which can lead to unintended interpretations. Constellation is concerned with the term sensing inputs, which may infer that testing on instrument transformers must be completed while they are energized. This proves difficult at a generating facility where most testing is completed during planned outages when this equipment is not energized.

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 1 Comment</th></tr>
<tr><td colspan="3">4. Response: Thank you for your comments. The SDT has modified the definition for clarity; the SDT intends that the output of these devices, measured at the relay, properly represents the primary quantities. Testing methods are not a part of the definition.</td></tr>
<tr><td>Hydro One</td><td>No</td><td>1. Hydro One suggests adding “Components including” in the beginning. This is because the word “components” has been used extensively throughout the standard and there is no mention of what constitutes a protection system component in the standard. The word “component” does find mention in FAQs, however, it is recommended to mention it in the main standard.
The revised definition should read as follows: Protective System Components including Protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers or other interrupting devices.
2. There is not enough clarity on whether a Distribution Provider (DP) will be able to clearly identify which all protection system components does it own and need to maintain. This is critical since NPCC had proposed a SAR to this effect which was not accepted by NERC citing that this concern will be incorporated in the revised standard.
3. Also, reference should be made to Project 2009-17 in which Y-W Electric Association, Inc. (Y-WEA) and Tri-State Generation and Transmission Association, Inc. (Tri-State) requested an interpretation of the term "transmission Protection System" and specifically whether protection for a radially-connected transformer protection system energized from the BES is considered a transmission Protection System and is subject to these standards.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.
1. The SDT believes that the suggested text does not add to the definition, and may actually lead to additional problems,</td></tr>
</table>

Organization	Yes or No	Question 1 Comment
such as an implication that the list within the definition is incomplete. **2. This issue is properly addressed within the Standard, not within the definition.** **3. This issue relates to the application of the standard, and is not part of the definition.**		
Pacific Northwest Small Public Power Utility Comment Group	No	1. It is still unclear whether relays that respond to mechanical inputs, such as sudden pressure relays, are included in the proposed definition as protective relays. While PRC-005-2 R1 limits the scope of that particular standard to protection systems that sense electrical quantities, it is remains unclear in other standards that use the defined term whether mechanical input protections are included. 2. We suggest that "Protective Relay" also be defined, and that the definition clearly exclude devices that respond to mechanical inputs in line with the NERC interpretation of PRC-005-1 in response to the CMPWG request.
Response: Thank you for your comments. **1. The definition has been modified to specify, "Protective relays which respond to electrical quantities".** **2. "Protective relay" is defined by IEEE and does not have a unique meaning when used in a NERC standard, thus the SDT sees no need to either modify or duplicate that definition.**		
Pepco Holdings, Inc. - Affiliates	No	It is still unclear whether relays that respond to mechanical inputs, such as sudden pressure relays, are included in the proposed definition as protective relays. While PRC-005-2 R1 limits the scope of that particular standard to protection systems that sense electrical quantities, it remains unclear in other standards that use the term "Protection System" (such as PRC-004) whether devices responding to mechanical inputs

Organization	Yes or No	Question 1 Comment
		are included. As such, we suggest that the term "Protective Relay" also be defined, and that the definition clearly exclude devices that respond to mechanical inputs in line with the NERC interpretation of PRC-005-1 in response to the CMPWG request.
Response: Thank you for your comments. **The definition has been modified to specify, "Protective relays which respond to electrical quantities".** **"Protective relay" is defined by IEEE and does not have a unique meaning when used in a NERC standard, thus the SDT sees no need to either modify or duplicate that definition.**		
PNGC Power	No	It is still unclear whether relays that respond to mechanical inputs, such as sudden pressure relays, are included in the proposed definition as protective relays. While PRC-005-2 R1 limits the scope of that particular standard to protection systems that sense electrical quantities, it is remains unclear in other standards that use the defined term whether mechanical input protections are included. We suggest that "Protective Relay" also be defined, and that the definition clearly exclude devices that respond to mechanical inputs in line with the NERC interpretation of PRC-005-1 in response to the CMPWG request.
Response: Thank you for your comments. **The definition has been modified to specify, "Protective relays which respond to electrical quantities".** **"Protective relay" is defined by IEEE and does not have a unique meaning when used in a NERC standard, thus the SDT sees**		

Organization	Yes or No	Question 1 Comment
no need to either modify or duplicate that definition.		
Duke Energy	No	It is unclear whether the revised definition includes PTs and CTs, but it does include the wiring. We don't see a way to list the wiring in R1.1 and provide supporting compliance evidence. We believe the phrase "and associated circuitry from the voltage and current sensing devices" should be struck from the definition.
Response: Thank you for your comments. The definition has been modified as suggested.		
Indeck Energy Services	No	It presumes that all relays in a plant are Protective Systems that affect BES reliability. As discussed at the FERC Technical Conference on Standards Development, the goal of the standards program is to avoid or prevent cascading outages--specifically not loss of load. The purpose of PRC-005-2 uses the term in its global sense but there is no subset of the Protection Systems that affect reliability. PRC-005 R1 requires identification of all components. With the broad definition proposed and no separate term for only relays and other components that have been identified as affecting reliability, confusion results. If this term has its global meaning, then another term, such as Reliability Protection Systems, should be instituted to avoid confusion.
Response: Thank you for your comments. The SDT believes that this issue is one for application of the definition within various standards, not one of the definition itself.		
Lincoln Electric System	No	LES believes the proposed definition of Protection System as written remains open to interpretation. LES offers the following Protection System definition for the SDT's consideration: "Protection System" is defined as: A system that uses measurements of

Organization	Yes or No	Question 1 Comment
		voltage, current, frequency and/or phase angle to determine anomalies and trips a portion of the BES and consists of 1) Protective relays, and associated auxiliary relays, that initiate trip signals to trip coils, 2) associated communications channels, 3) current and voltage transformers supplying protective relay inputs, 4) dc station supply, excluding battery chargers, and 5) dc control trip path circuitry to the trip coils of BES connected breakers, or equivalent interrupting device, and lockout relays.
Response: Thank your for your comments. The SDT has modified the definition to address some of the suggestions. Other elements of the suggestion do not add to the existing definition, and the SDT disagrees with the suggestions regarding “trip a portion of the BES” since Special Protection Systems and UVLS may actually trip non-BES facilities, and with excluding battery chargers.		
Long Island Power Authority	No	1. LIPA suggests adding “Protection System Components including” in the beginning. This is because the word “components” has been used extensively throughout the standard and there is no mention of what constitutes a protection system component in the standard. The word “component” does find mention in FAQs, however, it is recommended to mention it in the main standard. 2. Also, LIPA proposes a change in the proposed definition (changing "voltage and current sensing inputs" to "voltage and current sensing devices providing inputs").The revised definition should read as follows: Protective System Components including Protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers or other interrupting devices. 3. There is not enough clarity on whether a Distribution Provider (DP) will be able to clearly identify all protection system components it owns and needs to maintain. This is critical since NPCC had proposed a SAR to this effect which was not accepted by NERC citing that this concern will be incorporated in the revised standard.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comments. **1. The SDT believes that the suggested text does not add to the definition, and may actually lead to additional problems, such as an implication that the list within the definition is incomplete.** **2. The SDT has modified the definition as suggested regarding voltage and current sensing inputs.** **3. This issue is properly addressed within the Standard.**		
Progress Energy Carolinas	No	See comment associated with question 2.
Response: Thank you for your comments. Please see our response to your comment associated with question 2.		
Northeast Power Coordinating Council	No	1. Suggest adding “Protection System Components including” in the beginning. This is because the word “components” has been used extensively throughout the standard and there is no mention of what constitutes a protection system component in the standard. The word “component” does find mention in FAQs, however, it is recommended to mention it in the body of the standard. The revised definition should read as follows: Protection System Components including Protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers or other interrupting devices. 2. An alternative definition for Protection System to eliminate the need to capitalize “component”:The collective components comprised of protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit

Organization	Yes or No	Question 1 Comment
		breakers or other interrupting devices. 3. There is not enough clarity on whether a Distribution Provider (DP) will be able to clearly identify which protection system components it does own and needs to maintain. Many DPs own and/or operate equipment identified in the existing or proposed definition. However, not all such equipment translates into a transmission Protection System. The definition needs clarification on when such equipment is a part of the transmission protection system. This is critical since NPCC had proposed a SAR to this effect which was not accepted by NERC citing that this concern will be incorporated in the revised standard. Also, reference should be made to Project 2009-17 in which Y-W Electric Association, Inc. (Y-WEA) and Tri-State Generation and Transmission Association, Inc. (Tri-State) requested an interpretation of the term "transmission Protection System" and specifically whether protection for a radially-connected transformer protection system energized from the BES is considered a transmission Protection System and is subject to these standards.
Response: Thank you for your comments. **1. The SDT believes that the suggested text does not add to the definition, and may actually lead to additional problems, such as an implication that the list within the definition is incomplete.** **2. The SDT believes that the suggested text does not add to the definition, and may actually lead to additional problems, such as an implication that the list within the definition is incomplete.** **3. This issue relates to the application of the standard, and is not part of the definition.**		
Y-W Electric Association, Inc	No	The application of this definition to Reliability Standards NUC-001-2, PER-005-1, PRC-001-1, and PRC-004-1 results in confusion as to whether relays with mechanical inputs are included or excluded from this definition. PRC-005-2_R1 contains language limiting its applicability to relays operating on electrical inputs only, but the remaining standards that rely on this definition are not so specific. This being the case, it would make much more sense to clearly define what devices are actually meant in the glossary definition rather

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 1 Comment</th></tr>
<tr><td></td><td></td><td>than leaving it up to each individual standard to do so.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The definition has been modified to specify, “Protective relays which respond to electrical quantities”.</td></tr>
<tr><td>Arizona Public Service Company</td><td>No</td><td>1. The change to the definition relative to the voltage and current sensing devices is too prescriptive.
2. Methods of determining the integrity of the voltage and current inputs into the relays to ensure reliability of the devices should be up to the discretion of the utility.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.
1. The SDR modified the definition, relating to voltage and current sensing inputs, for clarity.
2. The issue regarding methods, etc, is an issue for the standard itself, not the definition.</td></tr>
<tr><td>MidAmerican Energy Company</td><td>No</td><td>The definition is expanded and clarified in the language of PRC-005-2. These changes should be incorporated in the definition to insure it is used consistently in PRC-005 and any other standards where it appears.

The following is a suggested revised definition:”Protection System” is defined as: A system that uses measurements of voltage, current, frequency and/or phase angle to determine anomalies and to trip a portion of the BES to provide protection for the BES and consists of 1) Protective relays for BES elements and, 2) Communications systems necessary for correct BES protection system operations and, 3) Current and voltage sensing devices supplying BES protective relay input and, 4) Station DC supply to BES protection systems excluding battery chargers, and 5) DC control trip paths to the trip coil(s) of the circuit breakers or other interrupting devices for BES elements.</td></tr>
</table>

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 1 Comment</th></tr>
<tr><td colspan="3">Response: Thank your for your comments.

The SDT modified the definition to address some of the suggestions. Bonneville Power Administration	Yes	
Clark Public Utilities	Yes	
Dynegy Inc.	Yes	
E.ON U.S.	Yes	
Entergy Services	Yes	
Exelon	Yes	
Indiana Municipal Power Agency	Yes	
Manitoba Hydro	Yes	
MEAG Power	Yes	
Northeast Utilities	Yes	
PacifiCorp	Yes	

Organization	Yes or No	Question 1 Comment
Springfield Utility Board	Yes	
US Bureau of Reclamation	Yes	
We Energies	Yes	
WECC	Yes	
Western Area Power Administration	Yes	
Florida Municipal Power Agency	Yes	Because the definition changes the scope of what a protection system covers, increasing that scope, the definition should not be balloted separately from PRC-005-2 so that the industry knows what is being committed to. For instance, the circuitry connecting the voltage and current sensing devices to the relays is a scope expansion. Station DC supply increases the scope to include the charger, etc. This scope increase needs to have an appropriate implementation period.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.		
NERC Staff	Yes	Still, to make sure the reference to dc supply is more generic than just "station dc supply," NERC staff suggests the following modified definition of Protection System:"Protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices, and any dc supply or control circuitry associated with

Organization	Yes or No	Question 1 Comment
		the preceding devices."
Response: Thank you for your comments. The SDT believes that modifying the definition as suggested does not add to the definition.		
FirstEnergy	Yes	1. The definition is ready for ballot with the addition of auxiliary relays to the definition of protective relays. There is a potential for an entity to determine that auxiliary relays do not perform a protection function since they typically do not sense fault current. Furthermore, one could determine that the term "circuitry" only refers to the wiring to connect the various DC devices together. We suggest adding "auxiliary relays necessary for correct operation of protective devices" to improve clarity of the definition. 2. With regard to the change from the current definition phrase "station batteries" to the new definitions phrase "station DC supply", it may not be clear to the reader that this includes battery chargers. To alleviate future interpretation issues, we suggest adding a clarifying statement at the end of the definition, such as "The station DC supply includes the battery, battery charger, and other DC components". 3. The acronym "dc" should be capitalized.
Response: Thank you for your comments. **1. The SDT believes that auxiliary relays are implicitly part of the control circuitry. The Supplementary Reference as posted in June 2010 (Section 15.3, page 22) specifically states that "the dc control circuitry also includes each auxiliary tripping relay …".** **2. Clarifications such as this properly belong in supplementary materials. This is described in the FAQ posted in June 2010 (FAQ II.5.A).** **3. The term, "dc", rather than "DC", reflects the NERC style guide.**		
ReliabilityFirst Corp.	Yes	The definition should probably include interrupting devices as the Protection System is of

Organization	Yes or No	Question 1 Comment
		little value if the fault cannot be interrupted.
Response: Thank you for your comments. Interrupting devices are not within the scope of this project.		
South Carolina Electric and Gas	Yes	The new definition effective date should be directly linked to the approval and implementation schedule of PRC-005-2 to avoid any possible compliance issues under the current PRC-005 standard.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.		
Ameren	Yes	1. We agree that the definition provides clarity and will enhance the reliability of the Protection Systems to which it is applicable; however, we suggest that a Glossary term for Protective Relay be added in order to clarify in all standards inclusion of relays that measure voltage, current, frequency and/or phase angle to determine anomalies, as stated in PRC-005-2 R1. 2. We believe there should be a direct linkage of the definition's effective date to the approval and implementation schedule of PRC-005-2. Since this new definition is directly linked to the proposed revised standard, it would be premature to make this definition effective prior to the effective date of the new standard. 3. We agree that the voltage and current inputs at the protective relays correctly identifies that component, that this excludes the instrument transformer itself. 4. We suggest replacing "to" with "at", and omitting "and associated circuitry from the voltage and current sensing devices."

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comments. **1. Thank you. “Protective relay” is defined by IEEE and does not have a unique meaning when used in a NERC standard, thus the SDT sees no need to either modify or duplicate that definition.** **2. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. Southern Company	Yes	We agree that the definition provides clarity and will enhance the reliability of the Protection Systems to which it is applicable. However, we feel that there needs to be a direct linkage

Organization	Yes or No	Question 1 Comment
Transmission		of the definition's effective date to the approval and implementation schedule of PRC-005-2. Since this new definition is directly linked to the proposed revised standard, it would be premature to make this definition effective prior to the effective date of the new standard.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.		
Santee Cooper	Yes	We agree with the proposed definition. However, the effective date of this definition should be linked to the implementation schedule of PRC-005-2. This definition should not be made effective prior to the new standard.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.		

2. Do you agree with the implementation plan for the revised definition of Protection System? The implementation plan has two phases – the first phase gives entities at least six months to update their protection system maintenance and testing program; the second phase starts when the protection system maintenance and testing program has been updated and requires implementation of any additional maintenance and testing associated with the program changes by the end of the first complete maintenance and testing cycle described in the entity's revised program. If you disagree with this implementation plan, please explain why.

Summary Consideration: Most commenters felt that the definition and its implementation should be linked to the approval and implementation of the revised standard. The retirement date for the existing definition, in the Implementation Plan, was developed upon advice of NERC Compliance staff and is intended to address a reliability gap caused by the existing definition. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now.

Additional commenters indicated that a 6-month implementation schedule for modifying their Protection System maintenance and testing program is insufficient. The SDT revised the first phase of the implementation plan to 12-months. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.

Organization	Yes or No	Question 2 Comment
WECC		Compliance agrees only if the original "Protection System" definition is in place for the interim implementation period, so that only the changes and or additions to the "Protection System" definition are covered under the proposed implementation plan.
Response: Thank you for your comments. The retirement date for the existing definition, in the Implementation Plan, was developed upon advice of NERC Compliance staff and is intended to address a reliability gap caused by the existing		

Organization	Yes or No	Question 2 Comment
definition.		
Public Service Enterprise Group ("PSEG Companies")	No	1. The draft implementation plan general considerations have a requirement to identify all the protection system components addressed under PRC-005-1 and PRC-005-2 for potential audits while modifying the existing programs. The standard revision will require extensive reviews and possibly add significant amounts of components to the program. This is listed as a requirement without a specific deadline other than supplying the information as part of an audit. If an audit is scheduled or announced early in the implementation period the evidence is required. The requirement for identifying all the components in the implementation process should have a time specified with bases for the starting point. 2. Where additional definition of a protection system scope boundary is determined as a result of the standard revisions, the implementation plan completion requirement should be at the end of next maintenance interval of that added protection system component. There may be situations where additional scope as determined by the additions or revisions to the standard and/or supporting reference material (e.g., an auxiliary contact input in a tripping scheme) would require going back and taking equipment out of service to perform that one check. To keep the maintenance and outage schedules coordinated the new requirements should be at the end of current cycles, not beginning.
Response: Thank you for your comments. **1. The posted implementation plan for the definition specifies that the program be updated by the end of the first calendar quarter six months following regulatory approvals. This establishes the requested schedule for the definition alone. Implementation of PRC-005-2 is discussed in the implementation plan for the standard.** **2. The posted implementation plan for the definition provides for the requested implementation by specifying, "and implement any additional maintenance and testing (required in Requirement R2 of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing) by the end of the first complete maintenance and testing cycle described in the entity's program description and basis document(s) following establishment of the program changes**		

Organization	Yes or No	Question 2 Comment
resulting from the revised definition".		
Ameren	No	As noted above, the implementation plan should be linked to the approval of PRC-005-2. Since this new definition is directly linked to the proposed revised standard, it would be premature to make this definition effective prior to the effective date of the new standard. Otherwise, entities must address equipment, documentation, work management process, and employee training changes needed for compliance twice within an unreasonably short timeframe. If PRC-005-2 receives regulatory approval in 1st quarter 2011, PSMP implementation along with this revised definition should be effective at the beginning of 2012 to coincide with the calendar year. These nine months will be needed to fully assess and address the necessary maintenance program documentation changes, maintenance system tool revisions, and personnel training needed to incorporate this new definition into our program.
Response: Thank you for your comments. The retirement date for the existing definition, in the Implementation Plan, was developed upon advice of NERC Compliance staff and is intended to address a reliability gap caused by the existing definition. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.		
SERC Protection and Control Sub-committee (PCS)	No	As noted above, the implementation plan should be linked to the approval of PRC-005-2. Since this new definition is directly linked to the proposed revised standard, it would be premature to make this definition effective prior to the effective date of the new standard.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this		

Organization	Yes or No	Question 2 Comment
reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.		
Florida Municipal Power Agency	No	As stated in response to Question 1, it is inappropriate to change the definition of Protection System for PRC-005-1 and the new definition should wait for the new standard. In all honesty, the new PRC-005-2 lays out the program anyway, so, any change to the definition needs to be accompanied by the commitment associated with that change.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.		
American Electric Power	No	As written, the implementation plan only specifies a time frame for entities to update their documentation for PRC-005-1 and PRC-005-2 compliance. The implementation plan also needs to give entities a time frame to address any required changes to their documentation for other standards that use the term "Protection System", including but not limited to NUC-001-2, PER-005-1, PRC-001-1, etc.
Response: Thank you for your comments. An assessment of the changes to the definition (posted with the first comment period), relative to the entire body of other NERC Standards using this defined term, determined that the changes are consistent with the other existing uses of the definition, and that no other implementation plan considerations were necessary. No comments were received relative to this assessment.		
American Transmission Company	No	1. ATC does not agree to the implementation plan proposed. While it makes common sense to proceed with R1 prior to proceeding with implementing R2, R3, and R4, the timeline to be compliant for R1 is too short. It will take a considerable amount of

Organization	Yes or No	Question 2 Comment
		resources to migrate the maintenance plan from today's standard to the new standard in phase one. ATC recommends that time to develop and update the revised program be increased to at least one year followed by a transition time for the entity to collect all the necessary field data for the protection system within its first full cycle of testing. (In ATC's case would be 6 years) To address phase two, ATC believes human and technological resources will be overburdened to implement this revised standard as written. The transition to implementing the new program will take another full testing cycle once the program has been updated. Increased documentation and obtaining additional resources to accomplish this will be challenging. 2. Implementation of PRC-005-2 will impact ATC in the following manner: a. Increase costs: double existing maintenance costs. b. Since there will be a doubling of human interaction (or more), it is expected that failures due to human error will increase, possibly proportionately. c. Breaker maintenance may need to be aligned with protection scheme testing, which will always contain elements that are include in the non-monitored table for 6 yr testing. d. ATC is developing standards for redundant bus and transformer protection schemes. This would allow ATC to test the protection packages without taking the equipment out of service. Further if one system fails, there is full redundancy available. With the current version of PRC-005-2, ATC would need to take an outage to test the protection schemes for a transformer or a bus, there is not an incentive to install redundant schemes. ATC is working with a condition based breaker maintenance program. This program's value would be greatly diminished under PRC-005-2 as currently written. 3. Consideration also needs to be given for other NERC standards expected to be passed and in the implementation stage at the same time, such as the CIP standards.
Response: Thank you for your comments. **1. This comment appears to address implementation of the draft Standard, not the definition.** **2. This comment appears to address implementation of the draft Standard, not the definition.**		

Organization	Yes or No	Question 2 Comment
3. Thank you.		
Duke Energy	No	Definition should be implemented concurrently with PRC-005-2.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.		
Consumers Energy Company	No	For entities that may not have included all elements reflected in the modified definition within their PRC-005-1 program, 6-months following regulatory approvals may not be sufficient to identify all relevant additional components, develop maintenance procedures, develop maintenance and testing intervals, develop a defendable technical basis for both the procedures and intervals, and train personnel on the newly implemented items. We propose that a 12-month schedule following regulatory approvals may be more practical.
Response: Thank you for your comments. The Implementation Plan has been modified to allow a 12-month schedule as suggested. However, to agree with the SDT Guidelines established by NERC, "end of the first calendar quarter" was modified to "first day of the first calendar quarter".		
Exelon	No	PECO would like to have the implementation plan provide at least 1 year for full implementation of the new standard. This will provide adequate time for development of documentation, training for all personnel, and testing then implementation of the new process(es).
Response: Thank you for your comments. The Implementation Plan has been modified to allow a 12-month schedule as suggested. However, to agree with the SDT Guidelines established by NERC, "end of the first calendar quarter" was modified to "first day of the first calendar quarter".		

Organization	Yes or No	Question 2 Comment
Progress Energy Carolinas	No	Progress Energy does not believe that the definition should be implemented separately from and prior to the implementation of PRC-005-2. We believe there should be a direct linkage between the definition's effective date to the approval and implementation schedule of PRC-005-2. Since this new definition should be directly linked to the proposed revised standard, it would be premature to make this new definition effective prior to the effective date of the new standard. We believe that changes to the maintenance program should be driven by the revision of the PRC standard, not by the revision of a definition.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.		
Pepco Holdings, Inc. - Affiliates	No	The 6 month time frame to update the revised maintenance and testing program is too short. Specifically identifying and documenting each component not presently individually identified in our maintenance databases, auxiliary relays, lock-out relays, etc. will require a major effort. We recommend at least one year.
Response: Thank you for your comments. The Implementation Plan has been modified to allow a 12-month schedule as suggested. However, to agree with the SDT Guidelines established by NERC, "end of the first calendar quarter" was modified to "first day of the first calendar quarter".		
Indeck Energy Services	No	The definition should not be implemented separate from PRC-002-2. The PRC-002-2 implementation plan would be adequate.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this		

Organization	Yes or No	Question 2 Comment
reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.		
E.ON U.S.	No	The first phase is only 3 months (per Implementation Plan) to update the program, not the 6 months as listed in this question. E.ON U.S. recommends that it should be a minimum of 6 months, regardless.
Response: Thank you for your comments. The Implementation Plan for the definition specifically indicated a 6-month (increased to 12-months in response to comments) implementation schedule to update the program. However, to agree with the SDT Guidelines established by NERC, "end of the first calendar quarter" was modified to "first day of the first calendar quarter".		
Santee Cooper	No	The implementation plan should be linked to the approval of PRC-005-2. The definition should not be made effective prior to the new standard.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.		
Xcel Energy	No	1. The implementation plans for both the definition and standard are confusing. Does this imply a "clean slate" approach can be used? i.e. do entities have up to the first interval window to complete the maintenance or must they have it complete on day 1 of the standard and again by the first interval? 2. It also appears that the implementation plans are conflicting whereby one requires full compliance and the other allows 6 months...the definition implementation plan also refer

Organization	Yes or No	Question 2 Comment
		to a basis document though the standard does not require one.
Response: Thank you for your comments. **1. The implementation plan for the definition specifically states that the entity has until the end of the first full interval established per their program and basis documents to implement the updated program (i.e. complete the maintenance).** **2. The Implementation Plan for the definition specifically indicated a 6-month (increased to 12-months in response to comments) implementation schedule to update the program. However, to agree with the SDT Guidelines established by NERC, "end of the first calendar quarter" was modified to "first day of the first calendar quarter". PRC-005-1 requires basis documents, where PRC-005-2 (draft) does not, as maximum intervals and minimum activities are prescribed within the standard.**		
Manitoba Hydro	No	The proposed implementation stage of 6 months is much too stringent and an 18 month window is suggested.
Response: Thank you for your comments. The Implementation Plan has been modified to allow a 12-month schedule. However, to agree with the SDT Guidelines established by NERC, "end of the first calendar quarter" was modified to "first day of the first calendar quarter".		
MidAmerican Energy Company	No	The protection system definition implementation plan should be consistent with the implementation plan of PRC-005-2 R1. Actual maintenance requirements implementation should be as required by the PRC-005-2 implementation plan and should not be included in the implementation plan for the protection system definition.
Response: Thank you for your comments.		
Southern Company Transmission	No	The revised definition should not be made effective until the revised PRC-005-2 is in effect. There is no definite reliability benefit to balloting this definition prior to the revised standard. If balloted and approved, entities would definitely have to modify their Protection System Maintenance and Testing Program methodology, but there is no obligation to or guarantee

Organization	Yes or No	Question 2 Comment
		of any additional maintenance being performed. PRC-005-2 includes this definition, the maintenance activities, and the intervals that will ensure execution of the maintenance and testing.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.		
Indiana Municipal Power Agency	No	The second part of the implementation effective date does not make sense and might be wrong. The second part talks about implementing any additional maintenance and testing (required in R2 of PRC-005-1- Transmission and Generation Protection system Maintenance and Testing); this is referring to version 1 of the standard and there should be no additional maintenance and testing added from version 1 of the standard, just version 2 which is the new version. Overall, the wording on this implementation plan needs to be made more clear about how the implementation plan will work.
Response: Thank you for your comments. The second part of the implementation plan for the definition allows the entity to implement any program changes that result from the modified definition systematically via the intervals establised to address those changes. The SDT believes that this portion of the implementation plan is clear.		
US Bureau of Reclamation	No	The Time Horizons are too narrow for the implementation of the standard as written. The SDT appears to have not accounted for the data analysis associated with performance based systems. The data collection, analysis, and subsequent decisions associated development of a maintenance program and its justification do not occur overnight especially with larger utilities. In addition, this new standard will require complete rewrite of an entities internal maintenance programs. The internal processes associated with these vary based on the size of the entity and its organizational structure. Since this standard is

Organization	Yes or No	Question 2 Comment
		so invasive into the internal decisions concerning maintenance, the standard should allow at least 18 months for entities to rewrite their internal maintenance programs to meet the program development requirements and 18 months to train the staff in the new program, incorporate the program into the entities compliance processes, and to implement the new program.
Response: Thank you for your comments. The Implementation Plan has been modified to allow a 12-month schedule to update the entities' program in accoradnce with the modified definition.		
Hydro One	No	1. The time provided for the first phase "at least six months" is too open ended and does not give entities a clear timeline. HYDRO ONE suggests 1 year for the first phase. 2. Also, HYDRO ONE suggests phasing out the second phase in stages.
Response: Thank you for your comments. **1. The Implementation Plan has been modified to allow a 12-month schedule as suggested. However, to agree with the SDT Guidelines established by NERC, "end of the first calendar quarter" was modified to "first day of the first calendar quarter".** **2. The SDT does not understand this comment.**		
Long Island Power Authority	No	1. The time provided for the first phase "at least six months" is too open ended and does not give entities a clear timeline. LIPA suggests 1 year for the first phase. 2. It is also suggested phasing out the second phase in stages.
Response: Thank you for your comments. **1. The Implementation Plan has been modified to allow a 12-month schedule as suggested. However, to agree with the SDT Guidelines established by NERC, "end of the first calendar quarter" was modified to "first day of the first calendar quarter".**		

Organization	Yes or No	Question 2 Comment
2. The SDT does not understand this comment.		
Northeast Power Coordinating Council	No	1. The time provided for the first phase "at least six months" is too open ended and does not give entities a clear timeline. Suggest 1 year for the first phase. 2. Suggest phasing out the second phase in stages.
Response: Thank you for your comments. **1. The Implementation Plan has been modified to allow a 12-month schedule as suggested. However, to agree with the SDT Guidelines established by NERC, "end of the first calendar quarter" was modified to "first day of the first calendar quarter".** **2. The SDT does not understand this comment.**		
Northeast Utilities	No	The time provided for the first phase "at least six months" is too open ended and does not give entities a clear timeline. Northeast Utilities suggests 1 year for the first phase.
Response: Thank you for your comments. The Implementation Plan has been modified to allow a 12-month schedule as suggested. However, to agree with the SDT Guidelines established by NERC, "end of the first calendar quarter" was modified to "first day of the first calendar quarter".		
Grant County PUD	No	There needs to be more clarity concerning the role of the 3 year audit during the implementation phase. Do the audit tests consist of varying proportions of -1 criteria and -2 criteria?
Response: Thank you for your comments. This comment appears to address implementation of the revised standard, not the revised definition.		
Constellation Power Generation	No	This does not match the implementation proposed for PRC-005-2. The implementation plan for revising the program is 6 months based on the "definition implementation" but R1 in

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 2 Comment</th></tr>
<tr><td></td><td></td><td>PRC-005-2 has a 3 month implementation plan.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The intent is to implement the definition and apply it to PRC-005-1 before PRC-005-2 becomes effective. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. Organization	Yes or No	Question 2 Comment
		program.
Response: Thank you for your comments. **1. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.** **2. The Implementation Plan for the definition has been modified to allow a 12-month schedule as suggested. However, to agree with the SDT Guidelines established by NERC, "end of the first calendar quarter" was modified to "first day of the first calendar quarter".**		
Clark Public Utilities	No	1. While the drafting team has done a great job of simplifying the implementation plan from the original draft 1 language, the current language has some ambiguities. I do not understand what the term "the end of the first calendar quarter six months following regulatory approvals" means. What is wrong with just saying "within nine months (or six months or twelve months) following regulatory approvals? Using the current language I would be inclined to assume it is six months so I can avoid a dispute (and quite possibly a notice of alleged violation) over a date. 2. Also, I am not sure what the term "the end of the first complete maintenance and testing cycle described in the entity's program description" means. It is quite likely that a registered entity will make the required definition change to its maintenance program (at approximately six months) and wind up with devices that need to be tested. Is the implementation plan attempting to provide some allowed time delay so the registered entity will not be out of compliance even though it has devices that are now beyond the maximum testing interval due to the definition change? The existing language implies that within approximately six months of regulatory approval, the maintenance program needs to be changed to incorporate the revised definition for Protection System.

Organization	Yes or No	Question 2 Comment
		However, the effective date for the revised maintenance program is going to be some date that corresponds with the end of the first complete maintenance and testing cycle in that program. I really don't understand what that time period is and I believe the drafting team needs to put in something that clears up this confusion. By testing cycle do you mean "maximum interval" as shown in the PRC-005 table? Do you mean the "maximum interval" that a registered entity includes in their maintenance program? If so, do you intend the implementation to be a different date for protection devices depending on the maximum testing interval? Or do you envision some date beyond the six months where the entire maintenance program (with the definition change) becomes effective and any registered entities with out-of-compliance issues would need to file mitigation plans?
Response: Thank you for your comments. **1. Within the US, NERC Standards are not mandatory and enforceable until approval by FERC. As established within the NERC Drafting Team Guidelines, the effective dates must be "the first day of the first calendar quarter after entities are expected to be compliant". The effective dates are always on the first day of a calendar quarter to make it easier for entities to track the effective dates of requirements. To agree with the SDT Guidelines established by NERC, "end of the first calendar quarter" was modified to "first day of the first calendar quarter".** **2. Continuing on the example above, if an entity then establishes a 3-calendar-year schedule for additional components as addressed by the definition, the entity must be fully compliant by the end of 2014.**		
We Energies	No	Wisconsin Electric does not agree with the six-month implementation requirement in the first phase. It is our position that a longer adjustment time is needed for entities to update their maintenance programs to implement the new definition. The new definition results in a significant increase in the scope of affected equipment and the documentation required to implement the program, and requires additional resources beyond present levels, including hiring and training. We estimate that this effort will require three years to fully implement.
Response: Thank you for your comments. The Implementation Plan for the definition has been modified to allow a 12-month		

Organization	Yes or No	Question 2 Comment
schedule to update the program. The entity then has the full interval as established within their program to implement the program for added components.

Consideration of Comments on 2nd Draft of the Standard for Protection System Maintenance and Testing Project 2007-17

The Protection System Maintenance and Testing Standard Drafting Team thanks all commenters who submitted comments on the 2nd draft of the PRC-005-2 standard for Protection System Maintenance and Testing. This standard was posted for a 45-day public comment period from June 11, 2010 through July 16, 2010. The stakeholders were asked to provide feedback on the standards through a special Electronic Comment Form. There were 58 sets of comments, including comments from more than 130 different people from over 70 companies representing 8 of the 10 Industry Segments as shown in the table on the following pages.

Many commenters objected to the establishment of maximum allowable intervals and offered comments on most of the individual activities and intervals within the Tables.

- The SDT responded that "FERC Order 693 and the approved SAR assigned the SDT to develop a Standard with maximum allowable intervals and minimum maintenance activities."

To provide more clarity, the SDT completely rearranged and revised the Tables.

- The Tables now consist of one table for each of the five Protection System component types, as well as a sixth table to address monitoring and alarming requirements to support extended intervals for monitored Protection System components.

Many commenters disagreed with some of the VRF and VSL assignments.

- The SDT made several modifications to the VRFs and VSLs that are in-keeping with the guidance provided by NERC and FERC.

Other comments were offered regarding Time Horizons, resulting in modification of the Time Horizons for both R3 and R4 from Long-Term Planning to Operations Planning.

In response to suggestions relative to the Measures, the SDT made changes to all four Measures.

Commenters were appreciative for the information contained in the two reference documents, but indicated a preference for some of the information to be included within the body of the Standard.

- In response, the SDT included the definitions of those terms exclusive to this standard, specifically "component type", "component", "segment", "maintenance correctable issue", and "countable event", within the Standard.

In this report, comments have been organized by question number. Comments can be viewed in their original format on the following web page:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herbert Schrayshuen, at 609-452-8060 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

1. **The SDT has made significant changes to the minimum maintenance activities and maximum allowable intervals within Tables 1a, 1b, and 1c, particularly related to station dc supply and dc control circuits. Do you agree with these changes? If not, please provide specific suggestions for improvement.**

Summary Consideration: Commenters expressed concerns with virtually all elements of posted Tables 1a, 1b, and 1c. In response to these comments, the Tables have been completely rearranged and extensively revised. The Tables now consist of one table for each of the five Protection System component types, as well as a sixth table to address monitoring and alarming requirements to support extended intervals for monitored Protection System components.

Several entities proposed extending the 3 month interval for unmonitored communication systems, and the drafting team did not adopt this suggestion because the SDT believes that three-months is necessary for these inspection-related activities related to communications systems

Organization	Yes or No	Question 1 Comment
Santee Cooper		No comment.
Xcel Energy		1. The current language is not aligned with the FAQ concerning the level of maintenance required for Dc Systems, in particular the FAQ states that with only 1 element of the Table 1b attributes in place the DC Supply can be maintained using the Table 1b activities, the table itself is clear that ALL of the elements must be present to classify the DC Supply as applicable to Table 1b. The FAQ needs to be aligned with the tables. 2. The FAQ also contains a duplicate decision tree chart for DC Supply. The FAQ contains a note on the Decision tree that reads, "Note: Physical inspection of the battery is required regardless of level of monitoring used", this statement should be placed on the table itself, and should include the word quarterly to define the inspection period.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. The FAQ has been modified. **2.** The FAQ has been modified.		
Pepco Holdings, Inc. - Affiliates		1. There were numerous comments submitted for Draft 1 indicating that the 3 month interval for verifying unmonitored communication systems was much too short. The SDT declined to change the interval and in their response stated: The 3 month intervals are for unmonitored equipment and are based on experience of the relaying industry represented by the SDT, the SPCTF and review of IEEE PSRC work. Relay communications using power line carrier or leased audio tone circuits are prone to channel failures and are proven to be less reliable than protective relays. Statistics on the causes of BES protective system misoperations, however, do not support this assertion. The PJM Relay Subcommittee has been tracking 230kV and above protective system misoperations on the PJM system for many years. For the six year period from 2002 to 2007, the number of protective system misoperations due to communication system problems were lower (and in many cases significantly lower) than those caused by defective relays, in every year but one. Similarly, RFC has conducted an analysis of BES protection system misoperations for 2008 and 2009, and found the number of misoperations caused by communication system problems to be in line with the number attributed to relay related problems. If unmonitored protective relays have a 6 year maximum maintenance/inspection interval, it does not seem reasonable to require the associated communication system to be inspected 24 times more frequently, particularly when relay failures are statistically more likely to cause protective system misoperations. As such, a 12 or 18 calendar month interval for inspection of unmonitored communication systems would seem to be more appropriate. FAQ II 6 B states that the concept should be that the entity verify that the communication equipment...is operable through a cursory inspection and site visit. However, unlike FSK schemes where channel integrity can easily be verified by the

Organization	Yes or No	Question 1 Comment
		presence of a guard signal, ON-OFF carrier schemes would require a check-back or loop-back test be initiated to verify channel integrity. If the carrier set was not equipped with this feature, verification would require personnel to be dispatched to each terminal to perform these manual checks. 2. The phrase “Verify Battery cell-to-cell connection resistance” has entered the table where it did not exist before. On some types of stationary battery units, this internal connection is inaccessible. On other types the connections are accessible, but there is no way to repair them based on a bad reading. And bad cell-to-cell connections within units will be detected by the other required tests. This requirement will cause entities to scrap perfectly good batteries just so this test can be performed, with no corresponding increase in bulk electric system reliability while taking an unnecessary risk to personnel and the environment.
Response: Thank you for your comments. 1. The SDT believes that the 3-month interval is proper for unmonitored communications systems. **2.** This element of the table has been modified to state, “Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)” to address this comment.		
Indeck Energy Services	No	
GDS Associates	No	Table 1a. Protective relays 1. For microprocessor relays need guidance in how all the inputs/outputs will be checked and how is determined which one are “essential to proper functioning of the Protection System” 2. For microprocessor relays need guidance in how the acceptable measurement is physically determined.

Organization	Yes or No	Question 1 Comment
Response: Thank you for comments. 1. The Standard is proscribed from describing “how.” Section 15.3 of the Supplementary Reference provides some guidance, but it is left to the entity to determine what methods best address their program. **2.** The Standard is proscribed from describing “how.” Section 15.3 of the Supplementary Reference provides some guidance, but it is left to the entity to determine what methods best address their program.		
Western Area Power Administration	No	1) Standard, Table 1a, “Control and trip circuits with electromechanical trip or aux contacts (except for microprocessor relays, UFLS or UVLS)”: Where would un-monitored control and trip circuits connected to a microprocessor relay fall, and what is the associated interval and maintenance activity? 2) Standard, Table 1a, “Control and trip circuits with electromechanical trip or aux contacts (except for microprocessor relays, UFLS or UVLS)”: Please confirm that the defined Maintenance Activity requires actual tripping of circuit breakers or interrupting devices. 3) Standard, Table 1a, “Control and trip circuits with unmonitored solid state trip or auxiliary contacts (except UFLS or UVLS)”: Please confirm that the defined Maintenance Activity requires actual tripping of circuit breakers or interrupting devices. 4) Standard, Table 1b. On page 13, for Protective Relays, please clarify the intent of “Conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming.” 5) Standard, Table 1b. On page 13, for Protective Relays, please clarify the intent of “Verify correct operation of output actions that used for tripping.” Does this require functional testing of a microprocessor relay, i.e., using a relay test set to simulate a fault condition? 6) Standard, Tables 1a and 1b: Would it be possible to provide an interval credit for full parallel redundancy from relay to trip coil? 7) Table 1a (page 9) Voltage and Current Sensing Inputs to Protective Relays and

Organization	Yes or No	Question 1 Comment
		associated circuitry – This maintenance activity statement implies that signal tests to prove the voltage and current are present is all that is required. Can this be accomplished by adding a step to the Relay Maintenance Job Plan to take a snapshot of the currents and potentials (In-Service Read) with piece of test equipment? 8) Table 1b (Page 14) Control and Trip Circuitry - Level 2 Monitoring Attributes for Component is too wordy and hard to understand the meaning. Does this whole paragraph mean that the dc circuits need to be monitored and alarmed? At what level does the dc control circuits need the alarming? Can this be at the control panel dc breaker output? 9) Table 1b (Page 15) Station Dc Supply - Should this be in Table 1c because the attributes indicate that the station dc supply cells and electrolyte levels are monitored remotely. To do a fully monitored battery system would be cost prohibitive and require a tremendous amount of engineering. 10) Voltage and Current Sensing Inputs to Protective Relays and associated circuitry - This maintenance activity statement implies that signal tests to prove the voltage and current are present is all that is required. Can this be accomplished by adding a step to the Relay Maintenance Job Plan to take a snapshot of the currents and potentials (In-Service Read) with piece of test equipment? 11) Table 1a and 1b (Page 11 and 16) Associated communications system - Western has monitoring capability on all Microwave Radio and Fiber Optics communications systems with the Communications Alarm System that monitors and annunciates trouble with all communications equipment in the communications network. The protective relays that use a communications channel on these systems have alarm capability to the remote terminal units in the substation. Since these are digital channels how does an entity prove channel performance on a digital system?

Response: Thank you for your comments.

1. The Tables have been rearranged and considerably revised to improve clarity. Please see the new Table 1-5.

Organization	Yes or No	Question 1 Comment
2. The Standard requires that breakers (except for those for UFLS/UVLS) be tripped at least once during each 6 calendar year interval. See new Table 1-5. 3. The Standard requires that breakers (except for those for UFLS/UVLS) be tripped at least once during each 6 calendar year interval. See new Table 1-5. 4. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1. 5. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1. 6. No. The SDT believes that it is important that all parallel paths be maintained within the indicated interval, and the prescribed interval already considers the reliability benefits of parallel tripping paths. 7. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3. It may be possible to do as suggested in some cases; a snapshot may be able to determine that voltage and current is present at the relay. However, the snapshot may not be sufficient to determine that the values are acceptable. 8. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 9. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. 10. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3. It may be possible to do as suggested in some cases; a snapshot may be able to determine that voltage and current is present at the relay. However, the snapshot may not be sufficient to determine that the values are acceptable. **11.** Many digital communications systems or digital relays themselves use bit-error-rate or other methods to monitor and alarm on channel performance – check the design of the equipment used.		
Southern Company Transmission	No	1) Comment on Control Circuitry - Below in Figure 1 is a previous version of Table 1. It clearly shows 3 levels of monitoring for Control Circuitry. For Unmonitored schemes such as EM, SS, unmonitored MP relays, you must do a complete functional trip test every 6 years. For partially monitored schemes such as MP relays with continuous trip coil/circuit monitoring, you must do a complete functional trip test every 12 years. For fully monitored schemes where all trip paths are monitored, you do not have to trip test the scheme but you still have to operate the breaker trip coils, EM aux/lockout relays every 6

Organization	Yes or No	Question 1 Comment
		years. This is very clear and reasonable. The latest version of Table 1 is not very clear or reasonable. The previous Partially Monitored control circuit monitoring requirements were deleted and the Fully Monitored control circuit monitoring requirements were moved to Partially Monitored requirements. We are not sure why this major change in philosophy was made?? This makes all of our MP relay control schemes that continuously monitor trip coils/circuits fall into the unmonitored category and therefore requires a 6 year full functional trip test. For a scheme that monitors 99+% of the control scheme (and probably 100% of the control scheme that actually has problems) to be considered Unmonitored does not seem logical or reasonable to us. This puts these “highly monitored” schemes in the same category and requires the same maintenance requirements / intervals as EM relays with no alarms whatsoever. This also seems to contradict the intent of the following statement from the Supplementary Reference doc on page 9: Level 2 Monitoring (Partially Monitored) Table 1b This table applies to microprocessor relays and other associated Protection System components whose self-monitoring alarms are transmitted to a location (at least daily) where action can be taken for alarmed failures. The attributes of the monitoring system must meet the requirements specified in the header of the Table 1b. Given these advanced monitoring capabilities, it is known that there are specific and routine testing functions occurring within the device. Because of this ongoing monitoring hands-on action is required less often because routine testing is automated. However, there is now an additional task that must be accomplished during the hands-on process - the monitoring and alarming functions must be shown to work. Recommendation - Please consider going back to the previous table as shown below in Figure 1. It seems much clearer and reasonable. Feel free to convert the old wording to the latest wording. Figure 1 - Previous Table - Control Circuitry See Figure 1 in email documentation sent to Al McMeekin. Current Table - Control Circuitry (see pdf file) See pdf file PRC-005-2_clean_20 10June88131418.pdf in email documentation sent to Al McMeekin. 2) Comments: The comments below are grouped by component type. The following (5) comments pertain to the maintenance intervals for protective relays:

Organization	Yes or No	Question 1 Comment
		a. Is the "verify acceptable measurement of power system input values" activity listed in the protective relay 6 year interval in Table 1a the same activity as the 12-year activity for Voltage and Current Sensing Inputs in the same table? b. Please clarify the meaning of "check the relay inputs and outputs" that are specified to be checked for microprocessor relays at the following table locations: the protective relay 6 year interval in Table 1a, the protective relay 12-year interval in Table 1b. Is this referring to a check of the relay internal input recognition and output control ending at the relay case terminals, or is this referring to a check extending to the source (and target) of all inputs and outputs to the relay? The latter interpretation results in a repeat of the maintenance required for dc control circuitry. c. Are the second, third, and fourth maintenance activities in the Table 1a Protective Relay, 6-year row those activities that apply to microprocessor relays? If so, we suggest rewording these items as follows: For microprocessor relays, verify that the settings are as specified, check the relay digital inputs and outputs that are essential to proper functioning of the Protection System, and verify acceptable measurement of power system analog input values." d. Please clarify the meaning of "Verify proper functioning of the relay trip contacts" found in protective relays with trip contacts 12 year interval in Table 1c. Is this verification a check of the relay internal contact to the relay case terminals or is this meant to be a trip check functional test? This category of component does not appear in table 1a or 1b. Should it? Is this activity the same as the protective relay Table 1b maintenance activity "output actions used for tripping"? If so, please make the wording match exactly to clarify. e. Table 1c introduces the use of "Continuous" Maximum Maintenance Intervals. This is inconsistent with the Table 1a and Table 1b usage of the interval. In Tables 1a and 1b this interval is used to describe the maximum time frame within which the activities shown in "Maintenance Activities" must be completed. The table column "Maintenance Activities" has been used to identify those activities which must be performed in addition

Organization	Yes or No	Question 1 Comment
		to those accomplished by the monitoring attributes. To maintain consistency in use of the interval and activity columns of Tables 1a, 1b, and 1c, each entry that uses the "Continuous" interval should be changed to N/A and the Maintenance Activities should be changed to either "No additional activities required" or "None, due to continuous automatic verification of the status of the relays and alarming on change of settings" [example given for Table 1c, Protective Relays] 3) The following (8) comments apply to Maintenance Tables 1a, 1b, and 1c for Station DC supplies. a. In Table 1a, Station dc supply, 18 calendar month, the verify item "Float voltage of battery charger" is not listed in Table 1b. Is this requirement independent of the level of monitoring and always required? If so, should it be added in to Table 1b and 1c, Station dc supply, 18 calendar months above the "Inspect:" section? b. The 6 year interval maintenance activity for NiCad batteries in Table 1a and Table 1b should read "station battery" rather than "substation battery". c. It is recommended to simplify the Station dc supply sections in each of the three maintenance tables by relocating the common items that do not change dependent upon the level of monitoring. Specifically, the following rows of each of the three tables have identical maintenance requirements that are independent of the level of monitoring. The tables would be significantly simplified if these "monitor level independent" requirements are moved outside of the table: I. Station dc supply; 18 calendar months; Inspect: " II. Station dc supply (that has a s a component Valve Regulated Lead Acid batteries) III. Station dc supply (that has as a component Vented Lead Acid batteries) IV. Station dc supply (that has as a component Nickel Cadmium batteries) V. Station dc supply (battery is not used)

Organization	Yes or No	Question 1 Comment
		d. Table 1a has 18 calendar month requirements for “Station dc supply (battery is not used)”. This category is missing from Table 1b - was this intentional? e. Table 1a has 6 calendar year and 18 calendar month requirements for “Station dc supply (battery is not used)”. This category is missing from Table 1c - was this intentional? f. Please clarify the meaning of “Battery terminal connection resistance”. Does this apply only to multi-terminal batteries? Is this referring to the cables external to the battery (to the charger and load panel)? g. Table 1c contains a Type of Protection System Component not found in any of the other tables: “Station dc supply (any battery technology). Is this the same as “Station dc supply” found in Tables 1a and 1b? h. The Level 3 Monitoring Attributes for “Station dc supply (any battery technology)” are identical to the Level 2 Monitoring Attributes for “Station dc supply”. This appears to be duplicative in description with two different “maximum maintenance intervals” and “maintenance activities” listed. 4) The following (3) comments pertain to the Voltage and Current Sensing Input component type: a. Why is “signals” bolded in the Table 1a row for this component type? b. Are the Table 1a, 12 year maintenance activities for this component type a duplication of the Table 1a, Protective relay, 6 year maintenance activity for microprocessor relays (verify acceptable measurement of power system input values)? c. Why is this component type highlighted in bold in Table 1c? 5) The following (8) comments pertain to the Control and Trip Circuit component type: a. Why are microprocessor relay initiated tripping schemes excluded from the 6 year

Organization	Yes or No	Question 1 Comment
		complete functional testing? The auxiliary relay operations resulting from these initiating devices are just as likely to stick (mis-operate) as those initiated from electromechanical devices. b. We propose simplifying Table 1a for this component type by grouping the two 6 year and the two 12 year interval maintenance lines into two rather than four table rows. The 6 year interval maintenance activities for the UFLS/UVLS systems could be addressed in the table row above using a parenthetical adder to the existing text = (for UFLS/UVLS systems, the verification does not require actual tripping of circuit breakers or interrupting devices). All of the other text in the UFLS/UVLS table row matches that found two rows above. The same parenthetical adder in the first 12 year interval row for this component type would eliminate the need for the (UFLS/UVLS Systems Only) row for 12 year intervals. c. If the two rows are combined as suggested previously - this comment is irrelevant: The Table 1a 6 year interval activity for UFLS/UVLS Systems Only is missing the word “contacts” after auxiliary. d. There appears to be no difference in the 6 year interval maintenance activities for this component type in Table 1a and Table 1b. Table 1b monitoring attributes include “Monitoring and alarming of continuity of trip circuits”, but the interval between electrically operating each breaker trip coil, auxiliary relay, and lockout relay remains at 6 years. What maintenance activity advantage do the Level 1b monitoring attributes provide? e. The difference between the two DC Control Circuits in Table 1b (on page 14) is unclear. What is the difference between the “Control Circuitry (Trip Circuits)” and the “Control and trip circuitry”? We propose combing the multiple table rows for this component type into a single line item for this component type, as it takes a combination of the protective relay action, any auxiliary relay, and the circuit breaker to comprise a complete tripping system. f. We have three questions on the monitoring attributes given for this component type on

Organization	Yes or No	Question 1 Comment
		page 14: I. Does the attribute beginning "Monitoring of Protection ..." indicate a requirement to monitor every input, every output, and every connection of every Protection System Component involved in each tripping scheme? II. Does the attribute beginning "Connection paths..." related to monitoring of communication paths? III. Does the attribute beginning "Monitoring of the continuity..." require the presence of coil monitoring of any auxiliary relay whose contact is encountered when tracing a tripping path from a protective relay to a breaker? g. Are the Table 1c attributes for this component type different from the monitoring described in Table 1b beginning "Connection paths..."? h. Are there no requirements to operate any relays functionally for "Protection System control and trip circuitry" in Table 1c? The devices need to be exercised some or they will not be reliable. 6) The following (1) comment pertains to the Associated communications system component type: The Table 1b monitoring attribute for this component type (communications channel monitor and alarm) clearly should (and does) eliminate the Table 1a, 3 month interval activity (verifying the communication system is functional). The common maintenance activities found in Table 1a (6 year) and Table 1b (12 year) should be same interval - either 6 or 12.

Response: Thank you for your comments.

1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5.
2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1 for all five of these

comments. 3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4 for all eight of these comments. 3f. Please see IEEE 450-2002 Appendix F, IEEE 1188-2005 Appendix D, and Section 6.3.2 of IEEE 1106-2005 for clarification of the meaning of “battery terminal connection resistance”. 4. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3 for all three of these comments. 5. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5 for all eight of these comments. 6. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-2 for this comment.		
Consumers Energy Company	No	1. If multiple redundant Protection System components, with associated parallel tripping paths, are provided, Table 1a, 1b, and 1c require that each parallel path be maintained, and that the maintenance be documented. Often, these multiple schemes are provided not to meet specific reliability-related requirements, but instead to provide operating flexibility. Testing these likely will require outages, and those outages may result in decreased reliability. Further, the documentation related to maintenance of all paths will be very cumbersome, and will lead to increased compliance exposure simply by its volume. This may perversely lead to entities NOT installing the redundant schemes, resulting in decreased reliability. 2. Many of the activities described in the Tables are not, by themselves, clear. The standard should include sufficient detail such that entities are clear as to what must be done for compliance, rather that relying on supplementary documents for this information. For example, it’s not clear, in Table 1a (Station DC Supply), what is meant by, “Verify that the dc supply can perform as designed when the ac power from the grid is not present.” Similarly, it isn’t clear from the general description within the Tables that components possessing different monitoring attributes within a single scheme, may be distinguished

Organization	Yes or No	Question 1 Comment
		such that differing relevant tables can be used for the separate components. 3. In Table 1a, Station DC Supply, one of two optional activities is to "Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. Battery assemblies supplied by some manufacturers have the connections made internally, making this option unavailable. Experience with ASME standards show that NERC and SDT members may be jointly and separately liable for litigation by specifying methods that either prefer or prohibit use of certain technologies. 4. Two of the four Maintenance Activities that begin with "Perform a complete functional trip ..." conclude with "... does not require actual tripping of circuit breakers or other interrupting devices. Do the other two such activities therefore require tripping of circuit breakers or other interrupting devices? 5. Performance of the minimum activities specified within Table 1a for legacy systems, particularly regarding control circuits, will require considerable disconnection and reconnection of portions of the circuits. Such activities will likely cause far more problems on restoration-to-service than they will locate and correct. We suggest that the SDT reconsider these activities with regard for this concern.

Response: Thank you for your comments.

1. The SDT believes that it is important that all parallel paths be maintained within the indicated interval, and the prescribed interval already considers the reliability benefits of parallel tripping paths.
2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5.
3. The use of the term "cell/unit" acknowledges that individual cells may not be accessible, but that assemblies of several cells (into units) may be available instead, and may be used to address this Requirement. An acceptable base-line value and follow-on tests may be acceptable for the entire station battery as a single unit.
4. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5.

Organization	Yes or No	Question 1 Comment
5. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. To the degree that performance history for the components within these systems is available, a performance-based program per Requirement R3 and Attachment A may be useful in these cases.		
JEA	No	1. R1.1 What is a Protection System component? Could the SDT provide a better understanding of what is meant by component? 2. R4: A "Failure to specify whether a component is being addressed by time-based, condition-based, or performance-based maintenance" by itself is a documentation issue and not an equipment maintenance issue. Suggest this warrants only a lower VSL, especially when one of the required components can only be time based. 3. R4: Suggest a stepped VSL for "Entity has failed to initiate resolution of maintenance-correctable issues". While we understand the importance of addressing a correctable issue, it seems like there should be some allowance for an isolated unintentional failure to address a correctable issue.
Response: Thank you for your comments. 1. A definition of "Component" has been added to the draft Standard. The SDT's intent is that this definition will be used only in PRC-005-2, and thus will remain with the Standard when approved, rather than being relocated to the Glossary of Terms. 2. This comment appears to be related to the VSL for Requirement R1, not Requirement R4 as indicated. The SDT disagrees that this is a "documentation" issue, and believes that that the related Requirement is fundamental to establishing an effective PSMP per this Standard. Also, this VSL is graded such that missing up to 5% of the required activity is indeed a Lower VSL. **3.** The VSL for Requirement R4 has been modified as suggested.		
Entergy Services	No	1. Table 1a has a "Control and trip circuits with electromechanical trip or auxiliary contacts (except for microprocessor relays, UFLS or UVLS)" component type listed, and there is a "Control and trip circuits with electromechanical trip or auxiliary [editorial comment: add 'contacts'] (UFLS/UVLS systems only)" component type listed. Suggest a "Control and trip circuits with electromechanical trip or auxiliary contacts" for a microprocessor relay

Organization	Yes or No	Question 1 Comment
		application should be addressed since it seems to be missing. 2. The term “check” has replaced “verify” for some of the maintenance activities in this draft version. What is the difference between these two terms, and shouldn’t “check” be defined if it is to be included as a PSMP activity term? 3. Assuming the term “check” replaced “verify proper functioning” in order to allow for the completion of a maintenance activity within the required interval and yet account for a maintenance correctable issue being present, suggest the other remaining activities in the tables where the term “verify proper functioning” is used, also be replaced with “check”. 4. Consider modifying the definition of “verification” to “A means of determining or checking that the component is functioning properly or maintenance correctable issues are identified”, eliminate use of the term “verify proper functioning” (which seems to be redundant by PRC-005-2 standard definition), and simply use the term “verify”.
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 2. “Check” is not an element of the PSMP definition. This term has been replaced throughout the tables with whatever term of the definition is relevant. 3. “Check” is not an element of the PSMP definition. This term has been replaced throughout the tables with whatever term of the definition is relevant. **4.** The terms within the PSMP definition have been revised to reflect the action (“verify” rather than “verification,” for example). The SDT believes that the use of the term “verify” within the modified tables and the definition of this component in the PSMP definition is appropriate and correct.		
MEAG Power	No	1. The descriptions for the "type of protection system components" do not appear to be consistent between Tables, 1a, 1b and 1c.

Organization	Yes or No	Question 1 Comment
		2. The maximum maintenance interval for a lead-acid vented battery is listed at 6 calendar years for performing a capacity test. This type of test has been proven to reduce battery life and an interval of 10 to 12 years would be better. 3. The maximum maintenance interval for "Station DC supply" was set at 3 months. This is too short of a period and 6 months would be better. 4. The control and trip circuits associated with UVLS and UFLS do not require tripping of the breakers but all other protection systems require tripping of the breakers, this appears to be inconsistent? 5. Digital relays have electromagnetic output relays. Do they fall into the electromechanical trip or solid state trip? 6. Need for clarification: The standard indicates that only voltage and current signals need to be verified. Does this mean that voltage and current transformers do not need to be tested by applying a primary signal and verifying the secondary output?

Response: Thank you for your comment.

1. The Tables have been rearranged and considerably revised to improve clarity and consistency. Please see new Table 1-5.
2. The SDT disagrees, and believes that a capacity test at 6-year levels is appropiate. A properly maintained battery, according to various credible references (from IEEE, EEI, EPRI, various manufacturers, etc.), can easily handle multiple deep discharges over its expected life.
3. The activity related to this interval is to verify various basic operating parameters. The SDT believes that extension of verification of these parameters beyond the interval within the Standard is inappropriate.
4. This is an intentional difference between UFLS/UVLS and the remainder of the Protection Systems addressed within the Standard, because of the distributed nature of UFLS/UVLS and because these devices are usually tripping distribution system elements.
5. These devices fall under “electromechanical output contacts.” The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1.

Organization	Yes or No	Question 1 Comment
6. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3.		
Ameren	No	Ameren does agree that draft 2 is a considerable improvement from draft 1 of PRC-005-2; however the following still need to be addressed. 1) Use “Control circuitry” to be consistent with the proposed definition. If ‘and trip’ was included so that users would know this is a trip circuit, then the definition should use ‘Trip circuitry’ instead of ‘Control circuitry’. It is important to use consistent terminology throughout the definition and the standard. 2) Please add row numbers in each of Tables 1a, 1b, and 1c, and arrange so that row 1 in each table corresponds, etc. (or state which rows correspond to each other.) This would help clarify movement from table to table. The number of sub clauses, nuances, and varied Type of Component descriptors among rows in the same table as well as from table-to-table can be overwhelming. This would help keep Regional Entities and System Owners from making errors. 3) Please clarify that the instrument transformer itself is excluded. The standard indicates that only voltage and current signals need to be verified. The FAQ seems to cover this, but see our comments on your question 6. 4) Clarifications need to be made on testing requirements on trip contacts relative to microprocessor vs. EM relays. Digital relays have electromagnetic output relays. Do they fall into the electromechanical trip or solid state trip? 5) There appears to be an inconsistency in the use of “check” vs. “verify” in the tables. Consider modifying the definition of “verification” to “A means of determining or checking that the component is functioning properly or that the maintenance correctable issues are identified”, eliminate use of the term “verify proper functioning” (which seems to be redundant by PRC-005-2 standard definition), and simply use the term “verify”. 6) Alternately if the term “check” replaced “verify proper functioning” in order to allow for the completion of a maintenance activity within the required interval and yet account for an

Organization	Yes or No	Question 1 Comment
		outstanding maintenance correctable issue being present, suggest the other remaining activities in the tables where the term "verify proper functioning" is used, also be replaced with "check". 7) If there is an intentional difference between "verify" and "check", shouldn't "check" be defined if it is to be included as a PSMP activity term? 8) Functional trip testing will require extensive analysis and could involve an extensive testing evolution to ensure the correct circuit is tested without unexpected trip of other components, particularly for generator protection systems and some transmission configurations. The complexity of the system and the test would be conducive to an error that resulted in excessive tripping, thus affecting the reliability of the BES. It would seem that the potential for an adverse affect from this test would be greater than the benefit gained of testing the circuit. In addition, scheduling outages to perform the functional trip testing in conjunction with other outages required to perform maintenance and other construction activities will be difficult due to the large number of outage requirements for the functional testing. This will challenge the BES more often and thus reduce reliability. For these reasons functional trip testing is too frequent, and should be extended to twelve years. 9) In battery maintenance table, we suggest that "cell/unit" be changed to "cell or unit." Suggest substituting "unit-to-unit" wherever "cell-to-cell" is used in the table now. Many batteries are packaged such that the individual cells are not accessible. 10) IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months due to storms and outages must set a target interval of two months thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, we also suggest that all intervals expressed as 3 calendar months be changed to 4 calendar months. 11) Replace "State of charge of the individual battery cells/units" with "Voltage of the

Organization	Yes or No	Question 1 Comment
		individual battery cells or units”. 12) The maximum maintenance interval for a lead-acid vented battery is listed at 6 calendar years for performing a capacity test. This type of test has been proven to reduce battery life and an interval of 10 to 12 years would be better. 13) The level 2 table regarding Protection Station dc supply states that level 1 maintenance activities are to be used, but then goes on to give a list of Maintenance Activities that don’t match those in level 1. Which activities shall we use? Same situation for Station DC Supply (battery is not used) where the 18 month interval is missing. 14) Also, Table 1B, in the second to last row, should be referring to UFLS rather than SPS.

Response: Thank you for your comments.

1. The Tables have been rearranged and considerably revised to improve clarity and consistency. Please see new Table 1-5.
2. The Tables have been rearranged and considerably revised to improve clarity and consistency. Please see new Table 1-5.
3. The definition has been modified to clarify that instrument transformers ARE part of the Protection System, and the maintenance activities in the new Table 1-3 specify WHAT must be done regarding this component type. The FAQ (II.3.A) is correct on this subject.
4. The Tables have been rearranged and considerably revised to improve clarity. These devices fall under “electromechanical output contacts.” The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1.
5. “Check” is not an element of the PSMP definition. This term has been replaced throughout the Tables with whatever term of the definition is relevant. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5.
6. “Check” is not an element of the PSMP definition. This term has been replaced throughout the Tables with whatever term of the definition is relevant. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5.
7. “Check” is not an element of the PSMP definition. This term has been replaced throughout the Tables with whatever term of the definition is relevant.
8. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5.

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 1 Comment</th></tr>
<tr><td colspan="3">9. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. This element of the table has been modified to state, “Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)” to address this comment.

10. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. The Requirement remains as “3 Calendar Months” and the SDT is not prescribing or suggesting what measures an entity may take within their program to assure compliance.

11. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. Verification of voltage of individual cells, etc., is one method; there are other ways.

12. The SDT disagrees, and believes that a capacity test at 6-year intervals is appropiate for Vented Lead Acid and Ni-Cad batteries. A properly maintained battery, according to various credible references (from IEEE, EEI, EPRI, various manufacturers, etc.), can easily handle multiple deep discharges over its expected life.

13. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4.

14. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-5.</td></tr>
<tr><td>American Transmission Company</td><td>No</td><td>ATC feels additional changes are needed.

1. The functional testing requirement should be altered or removed as it increases the amount of hands-on involvement and the opportunity for human error related outages to occur, thereby introducing more opportunities to decrease system reliability. As noted on p. 8 in the supplementary reference document, “Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.” By removing circuits from service on the proposed timelines for functional testing, the chance for human error is greater than a mis-operation from faulty wiring. Alternatively, entities may choose to schedule more planned outages to conduct their functional testing in order to limit the risk of unplanned outages resulting from human error. Under this scenario, more elements will be scheduled out of service on a regular basis, thereby reducing transmission system availability and weakening the system making it more challenging to withstand each subsequent contingency (N-1). Thus testing an in-tact</td></tr>
</table>

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 1 Comment</th></tr>
<tr><td></td><td></td><td>system is more desirable than taking it out of service for testing.

2. While the SDT has included language in the draft standard to use fault analysis to complete maintenance obligations, in practicality, this option does not offer any relief to taking outages to perform functional tests. Nearly all BES circuit breakers are equipped with dual trip coils. Identifying which trip coil operated for a fault only covers the one trip coil. Functional tests would still be needed on the other. The likelihood of having multiple trips on a given line in the course of several years is very low. Given it can take a year to schedule some outages, planning maintenance with random faults is unpractical and will create unacceptable risk to compliance violations. A better approach is to use the basis in schedule A, but extend this to cover the entire protection schemes. The document should establish target goals for mis-operation rates (dependability and security). This would allow the utilities to develop cost effective programs to increase reliability. The utilities would have incentives to replace poorly performing communications systems; they would be able to quantify the value of upgrading relay systems.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.

1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5.

2. Operational results, if desired by an entity, MAY be used to meet maintenance requirements to the degree that they verify, etc., the relevant performance. Whether their use is effective for a specific entity is left to the entity to determine. “Maintenance correctable issues,” which may result in part from misoperations, are a part of using Attachment A to develop a Performance Based PSMP.</td></tr>
<tr><td>Corporate Compliance</td><td>No</td><td>Battery visuals should be changed from 3 months to 6 months. Electrolyte levels of today’s lead-calcium batteries are relatively stable for a 6 month period compared to lead-antimony batteries used in the past.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The activity related to this interval is to verify various basic operating parameters. The SDT believes that extension of verification of these parameters beyond the interval within the Standard is inappropriate.</td></tr>
</table>

Organization	Yes or No	Question 1 Comment
Northeast Power Coordinating Council	No	1. Clarification is needed for “to a location where action can be taken”. Some examples in the FAQ will help in this clarification. 2. What type of documentation is required to show compliance that maintenance correctable issue has been reported? 3. Clarify the removal of requirement (see redline version, third row of Table 1a) for testing of unmonitored breaker trip coils. Is it the intention of the SDT to remove a requirement that would drive the industry to install TC monitors on breakers to improve reliability? 4. UFLS/UVLS DC control and trip circuits (Rows 5 and 6 of Table 1a) - Due to the distributed nature of this program, random failures to trip are not impactive to the overall operation of the UFLS protection. There should be no requirement to check the DC portion of these protections any more often than the DC circuit checks associated with that LV breaker. Since it is clear the requirement does not include the need to trip the breakers why the need to check the trip paths? Deletion of this requirement leaves the requirement to check only the relays and relay trip outputs from the protections every 6 years (or as often as the protective relay component type). Should the maintenance activities for “UVLS and UFLS relays that comprise a protection scheme distributed over the power system” not be the same as “Protective Relays”? V and I sensing to relays have a 12 year Maximum Maintenance Interval listed. It is good work practice to have this activity done the same time as maintenance activities associated with relay maintenance. 5. What is the basis for the various Maximum Maintenance Intervals listed in Table 1a? 6. From page 12 of the redline version, for "Station dc Supply (used only for UFLS and UVLS)", is the requirement applicable to distribution substations only? 7. For “Control and trip circuits with unmonitored solid-state trip or auxiliary contacts (UFLS/UVLS Systems only)” under Maintenance Activities - the word “complete: may be removed as it requires to actually trip the breakers. The sentence that tripping of the circuit breakers is not required contradicts with the word “complete”. More specifics are

Organization	Yes or No	Question 1 Comment
		required to spell out the adequate testing e.g. up to the lockout with the trip paths isolated etc. See Page 12 of the redline version. 8. For “Station dc Supply” having 18 calendar months as the Maximum Maintenance Interval, a battery has a 20 year life. IEEE standard PM is on a quarterly basis. What is the basis of the 18 calendar month interval? See page 12 of the redline version. 9. For “Associated communications systems” with a Maximum Maintenance Interval of 6 Calendar years, why is this required? The text "Verify proper functioning of communications equipment inputs and outputs that are essential to proper functioning of the Protection System. Verify the signals to/from the associated protective relay(s)" seems sufficient to ensure reliability. See page 15 of the redline version. 10. For “Relay sensing for Centralized UFLS or UVLS systems UVLS and UFLS relays that comprise a protection scheme distributed over the power system” under maintenance activities, clarify “overlapping segments”. What is the specified interval? Is actual breaker tripping required? See page 15 of the redline version. 11. On the row for Associated communications systems in Table 1c, in the Level 3 Monitoring Attributes for Component column, suggest a change in wording to: Evaluating the performance and quality of the channel as well as the performance of any interface to connected protective relays and alarming if the channel/protective relay connections do not meet performance criteria. 12. In Table 1c it is required to report the detected maintenance correctable issues within 1 hour or less to a location where action can be taken to initiate resolution of that issue. Even for a fully monitored protection system component it can be difficult to report the action in 1 hour. A 24 hour period for both Level 2 and Level 3 reporting of maintenance correctable issues is recommended.

Response: Thank you for your comments.

1. This is addressed in the Supplementary Reference document as posted with this draft (Section 8.1 and Section 13), and within the

Organization	Yes or No	Question 1 Comment
FAQ as posted with this draft Standard (V.3.D). 2. Specific effective forms of documentation are left to the entity to determine, but the SDT believes that this could include, among other things, work orders addressing the maintenance correctable issue. 3. The Tables have been rearranged and considerably revised to simplify and improve clarity. Please see new Table 1-5. Specifically to your comment, the SDT initially specified inspection of trip-coil monitoring functions at intervals of 3 months, with tripping otherwise requried annually. This has been revised to simply require tripping at 6-calendar-month intervals. 4. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 5. Please see Supplementary Reference, Section 8.3. 6. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. Specifically for this item, this applies to whatever interrupting device is being tripped by the UFLS/UVLS. To the degree that the same interrupting devices are tripped by other Protection System components, the relevant Requirements apply. 7. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 8. This interval is based on EPRI and other industry documents referencing these specific activities. 9. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3. 10. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1. 11. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3. **12.** The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 2. This requirement is now uniformly 24 hours as suggested within the comment.		
SERC Protection and Control Sub-committee (PCS)	No	1. Clarifications need to be made on testing requirements on trip contacts relative to microprocessor vs. EM relays. There appears to be an inconsistency in the use of “check” vs. “verify” in the tables. 2. Also, Table 1B, in the second to last row, should be referring to UFLS rather than SPS. 3. Also, note that M2 incorrectly excludes distribution provider.

Organization	Yes or No	Question 1 Comment
		4. In battery maintenance table, we suggest that “cell/unit” be changed to “cell or unit.”
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 3. Measure M2 has been corrected as suggested. **4.** The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4.		
BGE	No	Comment 1.1: In its decision to use “calendar years” with the maintenance intervals prescribed for most components the SDT has provided a framework that is consistent with a well-run PSMP but with enough flexibility to be practical. However BGE believes the application of this approach to short maintenance intervals, like three months for some battery maintenance will risk numerous violations due to practical scheduling constraints that are not a realistic threat to reliability. As the requirements are presently defined the inherent flexibility for battery maintenance that is nominally done on three month intervals may be as long as 1/3 of the interval or as short as one day (Our interpretation: Maintenance last done on January 1 is next due on April 1 and can be done no later than April 30. Maintenance done on Jan 31 is next due on April 30 and is overdue if done on May 1). The only practical solution is to increase the frequency so that the average intervals are significantly shorter than the nominal requirement.BGE recommends an alternate formulation for intervals if the nominal interval is less than one year. Some possible alternatives (assuming a three month nominal interval): Once per calendar quarter no later than the end of the quarter no earlier than one month before it. Four times per year, no more than 120 days apart no less than 60. Comment 1.2: On page 11, Row-3/Column-1 of Table-1a includes the following entry for functional trip testing:"Control and trip circuits with electromechanical trip or auxiliary contacts (except for microprocessor relays, UFLS or UVLS)". It is not clear why

Organization	Yes or No	Question 1 Comment
		electromechanical trip contacts in microprocessor relays are excluded. Comment 1.3: On page 12, Row-3/Column-3 of Table-1a includes the following Verification Task for Station DC Supplies: "Verify Battery cell-to-cell connection resistance". Multiple cell units do not provide the ability to measure cell-cell resistance.
Response: Thank you for your comments. 1. The intervals remain as prescribed within the Standard and are designed to be effective, clear, and consistently monitored for compliance; the SDT is not prescribing or suggesting what measures an entity may take within their program to assure compliance. 2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. **3.** This element of the table has been modified to state, “Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)” to address this comment.		
Constellation Power Generation	No	1. Constellation Power Generation (CPG) does not agree with the maximum maintenance interval for associated communication systems and station dc supply that has as a component any type of battery, which is 3 months. If the intent of the drafting team was to make this test quarterly (as recommended in IEEE-450), than the maximum interval should be 4 months. As written, for a registered entity to ensure they complete this test in an interval less than 3 months, they will most likely complete this test every 2 months. This causes two additional and unwarranted tests every year. CPG recommends an alternate formulation for intervals if the nominal interval is less than one year. Some possible alternatives (assuming a three month nominal interval): Once per calendar quarter no later than the end of the quarter no earlier than one month before it. Four times per year, no more than 120 days apart no less than 60. 2. CPG does not agree with differentiating between the different battery types. A suggestion would be to take the maximum maintenance interval for all the battery types, which is 6 years, and apply them across all types of batteries, eliminating the need to

Organization	Yes or No	Question 1 Comment
		differentiate between them. Furthermore, multiple cell units do not provide the ability to measure cell-cell resistance, and so that requirement should be removed. 3. CPG is not clear why electromechanical trip contacts in microprocessor relays are excluded in Table 1a.
Response: Thank you for your comments. 1. The intervals remain as prescribed within the Standard and are designed to be effective, clear, and consistently monitored for compliance; the SDT is not prescribing or suggesting what measures an entity may take within their program to assure compliance. 2. The appropriate maintenance activities and intervals differ considerably for various battery types. This element of the table has been modified to state, “Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)” to address this comment. **3.** The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1.		
Exelon	No	Exelon does not completely agree with the minimum maintenance activities and maximum allowable intervals as suggested by SDT. Comments on minimum maintenance activities: 1. Reference Table 1a (Page 11) of Standard PRC-005-2: With regard to the maintenance activity: "Verify that the station battery can perform as designed by conducting a performance ......". The standard should clearly define what is meant by "perform as designed" to eliminate ambiguity in future interpretations. 2. Also, Table 1a Station dc supply (that has as a component Vented Regulated Lead-Acid batteries) discusses “modified performance capacity test of the entire battery bank”. This needs additional clarification or should be reworded because modified test includes both the performance test (which is the capacity test) and the service test. Should be reworded to be “modified performance test”. 3. Comments on maximum allowable intervals: Nuclear generating stations have refueling outage schedule windows of approximately

Organization	Yes or No	Question 1 Comment
		18 months or 24 months (based on reactor type). If for some reason the schedule window shifts by even a few days, an issue of potential non-compliance could occur for scheduled outage-required tasks. The possibility exists that a nuclear generator may be faced with a potential forced maintenance outage in order to maintain compliance with the proposed standard. For the requirements with a maximum allowable interval that vary from months to years (including 18 Months surveillance activities), the SDT should consider an allowance for NRC-licensed generating units to default to existing Operating License Technical Specification Surveillance Requirements if there is a maintenance interval that would force shutting down a unit prematurely or face non-compliance with a PRC-005 required interval. Therefore, Tables 1a, 1b & 1c should include an allowance for any equipment specifically controlled within each licensee's plant specific Technical Specifications to implement existing Operating License requirements if such a conflict were to occur. Please see additional comments under Q7.
Response: Thank you for your comments. 1. This concern is addressed within IEEE standards (specifically IEEE 450, IEEE 1188, and IEEE 1106) by their description and definition of a "performance test" as further established within this requirement. The SDT believes that entities involved in battery maintenance will be familiar with these IEEE standards. 2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. **3.** The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. It is left to the the entity to determine how to align these requirements with requirements of other regulations and with operational concerns. Entities should be able to complete the activities with 18-month or shorter intervals without outages. See the SDT responses to your comments in Question 7.		
Black Hills Power	No	1. For Protective Relays, Table 1a Maintenance Activities has no requirement for verifying output contacts on non-microprocessor based relays. The actual contacts used for tripping should be verified by this activity.

Organization	Yes or No	Question 1 Comment
		2. For Protective Relays, Table 1b Maintenance Activities states “Verify correct operation of output actions that are used for tripping”. This requirement is vague and needs to define whether all protection logic or conditions that would initiate a relay trip output are required to be simulated and tested to the relay tripping output contact. 3. For Voltage and Current Sensing Inputs to Protective Relays and associated circuitry, Table 1a references “current and voltage signals” and Table 1b references “current and voltage circuit signals”. Need consistency or definitions to meet this requirement. 4. For Control and trip circuits with electromechanical trip or auxiliary (UFLS/UVLS Systems Only), Table 1a states “except that verification does not require actual tripping of circuit breakers or interrupting devices.” This exception to the requirement seems to defeat the whole purpose of the standard and leaves a huge gap open to interpretation and conflict. -For Control and trip circuits with unmonitored solid-state trip or auxiliary contacts (UFLS/UVLS Systems Only), Table 1a states “except that verification does not require actual tripping of circuit breakers or interrupting devices.” This exception to the requirement seems to defeat the whole purpose of the standard and leaves a huge gap open to interpretation and conflict. 5. For Station dc supply, Table 1a requirement includes “Inspect: The condition of non-battery-based dc supply.” This is redundant with the requirements of the section Station dc supply (battery is not used) and should be removed from this section. 6. For Voltage and Current Sensing Inputs to Protective Relays and associated circuitry, a maximum interval of verification of 12 years seems to contradict the intent of the rest of the Maintenance standard which dictates 6 years on all of the other components. The requirement for these components should fall in line with the rest of the standard.

Response: Thank you for your comments.

1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1.
2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1. “Verify” is defined within

Organization	Yes or No	Question 1 Comment
the PSMP defintion. 3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3. 4. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. This is an intentional difference between UFLS/UVLS and the remainder of the Protection Systems addressed within the Standard, because of the distributed nature of UFLS/UVLS and because these devices are usually tripping distribution system elements. 5. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. **6.** The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3. These devices are not typically subject to in-service degradation to the degree that those with 6-year intervals are. Entities have the latitude to perform maintenance more frequently than specified if they feel that such maintenance is needed.		
Duke Energy	No	General comment - the draft changes the word “verify” to “check” in several places; should use consistent phrasing throughout the standard. With regards to Table 1a, we have the following comments: 1. Control and trip circuits with electromechanical trip or auxiliary contacts (except for microprocessor relays. UVLS or UFLS) - We believe that while there may be value in a 6 calendar year cycle, this will be difficult to accomplish, since you either have to get outages scheduled or block protection, which risks reliability. Since this is essentially a re-commissioning check, the cycle should be 12 calendar years. Also 6 years appears to be in conflict with the system protection standard. 2. Control and trip circuits with unmonitored solid-state trip or auxiliary contacts (except for UVLS or UFLS) - agree with 12 calendar years as consistent with electromechanical above. 3. Control and trip circuits with electromechanical trip or auxiliary (UVLS or UFLS Systems Only) - 6 year cycle should be changed to 12 calendar years (see comment above on non-UVLS/UFLS). 4. Control and trip circuits with unmonitored solid-state trip or auxiliary contacts (UVLS or

Organization	Yes or No	Question 1 Comment
		UFLS Systems Only) - agree with change to 12 calendar years. 5. Station dc Supply (used only for UVLS or UFLS) - Strike the word “Station”. We don’t differentiate between dc supply used for UFLS and other protection. 6. Station dc supply - Change 18 calendar months to 24 months, since this testing requires generator outages. Nuclear plant fuel cycles can be longer than 18 months. 7. Associated communications systems - More clarity is needed regarding what is to be included in the definition of “Associated”.

Response: Thank you for your comments. “Check” is not an element of the PSMP definition. The term has been replaced throughout the tables with whatever term of the definition is relevant.

1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. The circuit itself is 12 years, but interval for the electromechanical devices such as aux or lockout relays remains at 6 years, as these devices contain “moving parts” which must be periodically exercised to remain reliable.
2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5.
3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5.
4. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5.
5. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4.
6. The SDT believes the specified intervals and activities are technically effective, and in a fashion that may be consistently monitored for compliance. The entity must determine how to best align these requirements with requirements of other regulations and with operational concerns. Entities should be able to complete the activities with 18-month or shorter intervals without outages.
7. This portion of the definition of Protection System has been modified for clarity. Also, the Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3.

Organization	Yes or No	Question 1 Comment
American Electric Power	No	1. In Table 1a for the component “Station dc Supply (used only for UVLS and UFLS)”, the

Organization	Yes or No	Question 1 Comment
		interval prescribed is "(when the associated UVLS or UFLS system is maintained)" and the activity is to "verify the proper voltage of the dc supply". The description of the interval "(when the associated UVLS or UFLS system is maintained)" needs to be changed. Relay personnel do not generally take battery readings. The interval should read "according to the maximum maintenance interval in table 1a for the various types of UFLS or UVLS relays". The testing does not need to be in conjunction with the relay testing, it is only the test interval that is important, although relay operation during relay testing is a good indicator of sufficient voltage of the battery. 2. The monitoring and/or maintenance activities listed for batteries are not appropriate in Tables 1b and 1c. There are no commercial battery monitors that monitor and alarm for electrolyte level of all cells. Why not move the electrolyte level to the 18 month inspection and actually open the possibility of condition monitoring to commercially available devices? Or give an option to do the electrolyte check at other time intervals (perhaps 12 months) by visual electrolyte inspection and still allow the monitoring of other functions on the listed 6 year schedule using condition monitoring. It makes no sense to prescribe an unattainable condition monitoring solution. The way that the tables are written, there is no advantage to use the charger alarms since battery maintenance requirements are not reduced in any way.
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. **2.** The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4.		
Great River Energy	No	1. In Table 1a section-Station DC Supply - 18 calendar months, under Maintenance Activities column, suggest changing under Verify: Battery terminal connection resistance To: Entire battery bank terminal connection resistance (This could have been interpreted as individual batteries) And change: Battery cell-to-cell connection resistance To: Battery cell-to-cell connection resistance, where an external mechanical connection is available.

Organization	Yes or No	Question 1 Comment
		2. In Table 1a-Station dc supply (that has a component Valve Regulated Lead-Acid batteries) suggest changing Max Maintenance Interval=3 Calendar Years or 3 Calendar Months to 4 Calendar Years or 12 Calendar Months. Our concern is that the insurance companies may push NERC maintenance intervals on all battery banks not associated with the BES. 3. Table 1a-Station dc supply (that has as a component Lead-Acid batteries) Max Maintenance Interval=6 Calendar Years suggest changing to 10 Calendar Years. Reason: performance tests may degrade the battery. 4. Table 1a-Station dc supply (that has as a component Nickel-Cadmium batteries) Max Maintenance Interval=6 Calendar Years suggest changing to 10 Calendar Years. Reason: performance tests may degrade the battery. 5. Table 1b -Level 2 Monitoring Attributes for Component in the row labeled (Control and trip circuitry) we suggest the following change: If a trip circuit comprises multiple paths, at least one of those paths is monitored. Alarming for loss of continuity or dc supply for trip circuits is reported to a location where action can be taken. 6. While all tripping circuits are not completely monitored, the trip coils and the outdoor cable runs are completely monitored. The only portion that would not be monitored is a portion of inter and intra-panel wiring having no moving parts located in a control house. Our company has extremely low failure rate of panel wiring and terminal lugging. I don't think that there is provision for moving control and trip circuitry to performance based maintenance? This control circuitry should be maintained less frequent than un-monitored trip circuits (6 years).

Response: Thank you for your comments.

1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. This element of the Table has been modified to state, "Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)" to address this comment.

Organization	Yes or No	Question 1 Comment
2. NERC Standards are limited to facilities and equipment related to the BES. How the Standard may be otherwise used is outside the scope of NERC Standards. 3. The SDT disagrees, and believes that a performance test at 6-year intervals is appropiate for Ni-Cad batteries. A properly maintained battery, according to various credible references (from IEEE, EEI, EPRI, various manufacturers, etc.), can easily handle multiple deep discharges over its expected life. 4. The SDT disagrees, and believes that a performance test at 6-year intervals is appropiate for Vented Lead Acid and Ni-Cad batteries. A properly maintained battery, according to various credible references (from IEEE, EEI, EPRI, various manufacturers, etc.), can easily handle multiple deep discharges over its expected life. 5. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. **6.** The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. Nothing in the draft Standard (including Attachment A) precludes an entity from using performance-based maintenance for dc control circuits.		
Long Island Power Authority	No	1. In Table 1c it is required to report the detected maintenance correctable issues within 1 hour or less to a location where action can be taken to initiate resolution of that issue. Even for a fully monitored protection system component it can be difficult to report the action in 1 hour. LIPA recommends a 24 hour period for both Level 2 and Level 3 reporting of maintenance correctable issues. The time identified is report time and not response time to correct issue. 2. LIPA seeks clarification on “to a location where action can be taken”. Some examples in the FAQ will help in this clarification. 3. What type of documentation is required to show compliance that maintenance correctable issues have been reported? 4. What is the basis of the various Maximum Maintenance Intervals tabulated in Table 1a-Time based maintenance?
Response: Thank you for your comments.		

Organization	Yes or No	Question 1 Comment
1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 through 1-5 and Table 2. These Tables reflect your proposed change. 2. This is addressed in the Supplementary Reference document as posted with this draft (Section 8.1 and Section 13), and within the FAQ as posted with this draft Standard (V.3.D). 3. Specific effective forms of documentation are left to the entity to determine, but the SDT believes that this could include, among other things, work orders addressing the maintenance correctable issue. **4.** Please see Section 8.3 of the Supplementary Reference document.		
Northeast Utilities	No	1. In Table 1c it is required to report the detected maintenance correctable issues within 1 hour or less to a location where action can be taken to initiate resolution of that issue. Even for a fully monitored protection system component it can be difficult to report the action in 1 hour. Recommend a 24 hour period for both Level 2 and Level 3 reporting of maintenance correctable issues. 2. Additionally, please clarify meaning of “to a location where action can be taken”.
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 through 1-5 and Table 2. These tables reflect your proposed change. **2.** This is addressed in the Supplementary Reference document as posted with this draft (Section 13), and within the FAQ as posted with this draft Standard (V.3.D).		
MidAmerican Energy Company	No	1. In the tables trip circuit has been replaced by “control and trip circuit”. From the context of the standard and the reference and frequently asked question documents it is clear that the requirement is to test the trip circuit only. Adding the word “control’ introduces ambiguity and the potential to imply the closing circuit of the interrupting device also requires testing under the standard. The word “control” should be removed. On this same subject the nomenclature in Table 1b for type of protection system component is

Organization	Yes or No	Question 1 Comment
		not consistent with Table 1a.In Table 1b in the Level 2 Monitoring Attributes for Component column for Relay sensing for centralized UFLS or UVLS systems there is a reference to SPS. This reference should likely be to UFLS/UVLS. 2. In Table 1a functional testing of associated communications systems is included with a maximum maintenance interval of 3 calendar months. Testing of this equipment at that frequency is not believed to be necessary. It is suggested that the interval be changed to 12 calendar months. 3. For control and trip circuit maintenance the requirement includes “a complete functional trip test”. In order to accomplish this type of testing given current design of lock-out relay and interrupting device trip circuitry multiple breakers and line terminal outages would be required simultaneously. In addition complete functional testing has the potential to result in unintentional tripping of equipment that could cause equipment damage and customer outages. Segmentation of trip circuits by lifting wires has the potential for incorrect restoration following testing. This type of testing has the potential to degrade system reliability as multiple entities schedule this work. An alternate to complete functional testing that does not potentially degrade system reliability should be substituted.
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 2. The SDT believes that the 3-month interval is proper for unmonitored communications systems. **3.** The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. The interval for maintenance of electromechanical devices such as aux or lockout relays remains at 6 years, as these devices contain “moving parts” which must be periodically exercised to remain reliable.		
Nebraska Public Power District	No	1. It would be very helpful in Table 1a, 1b, and 1c to reference the FAQ or Supplemental Reference by page number and section number for the corresponding

Organization	Yes or No	Question 1 Comment
		Maintenance Activity statements. 2. Table 1a, Control and Trip Circuits with electromechanical trip or auxiliary contact - how is the control and trip circuit functional trip test performed without affecting the BES or without tripping more than just the breaker (trip coil)? What is the basis for an actual trip of the breaker that will affect the BES? Functional trip testing will require extensive analysis and could involve an extensive testing evolution to ensure the correct circuit is tested without unexpected trip of other components, particularly for generator protection systems. The complexity of the system and the test would be conducive to an error that resulted in excessive tripping, thus affecting the reliability of the BES. It would seem that the potential for an adverse affect from this test would be greater than the benefit gained of testing the circuit. In addition, scheduling outages to perform the functional trip testing in conjunction with other outages required to perform maintenance and other construction activities will be difficult due to the large number of outage requirements for the functional testing. This will challenge the BES more often and thus reduce reliability. 3. 2. Table 1a, Control and Trip circuits with electromechanical trip or auxiliary contacts - What is the differentiation between control and trip circuits? The FAQ appears to use the term interchangeably. 4. Table 1a, associated communication systems - What is the basis for checking that the associated communication equipment is functioning every 3 calendar months for unmonitored components? NPPDs experience indicates that a check every 6 months is sufficient.

Response: Thank you for your comments.

1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 through 1-5. Doing as you suggest would make the supporting information with the FAQ and Suppementary Reference part of the Standard, and this would add extensive and unnecessary prescription to the Standard.

2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. These devices contain

Organization	Yes or No	Question 1 Comment
“moving parts” which must be periodically exercised to remain reliable. 3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. The FAQ has been modified. 4. The SDT believes that the 3-month interval is proper for unmonitored communications systems.		
Y-W Electric Association, Inc.	No	Many of the changes to the proposed standard are reasonable and improve the clarity of the standard and its requirements. However, Y-WEA concurs with Central Lincoln and FMPA on their comments regarding the testing of battery cell-to-cell connection resistance. Many types of stationary batteries are actually blocks of two or more cells that are internally connected. This requirement would necessitate either some sort of feasibility exception process (which, as shown by the TFE process with the CIP standards can be very difficult, cumbersome, and time-consuming to develop and administer) or replacement of the batteries in question, which would pose enormous burdens on small entities that must comply with this standard. The language in this requirement should be changed from “cell-to-cell” to “unit-to-unit” in order to avoid these issues.
Response: Thank you for your comments. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. This element of the table has been modified to state, “Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)” to address this comment.		
Progress Energy Carolinas	No	1. The modified definition of “Protection System” (page 2 of the clean version of PRC-005-2) uses the terminology “control circuitry associated with protective functions” whereas Table 1a rows 3-6, Table 1b Rows 3 and 5, and Table 1c Row 4 uses the terminology “control and trip circuits.” This is a conflict. “Control” implies that the standard applies to closing/reclosing circuits as well. We do not believe that is the intent. 2. Row 7 of Table 1a (page 10 of the clean version of PRC-005-2) indicates that proper

Organization	Yes or No	Question 1 Comment
		voltage of the station dc supply must be verified when the associated UVLS or UFLS maintenance is performed. It is not clear whether this requirement is over and above the quarterly and 18-month battery maintenance listed elsewhere in the table or is it the only battery maintenance required for UVLS and UFLS systems? If the intent is to check the station dc supply only when UVLS and UFLS maintenance is performed, the other rows addressing station dc should be revised to exclude UVLS and UFLS. 3. Row 4 of Table 1b (page 14 of the clean version of PRC-005-2) indicates that remote alarms must be verified every twelve calendar years for control circuitry (trip circuits) (except UFLS/UVLS) provided “Monitoring of Protection System component inputs, outputs, and connections” exists. Clarification should be made to indicate how to monitor inputs. For example, a breaker auxiliary switch is relied upon to communicate breaker status to a protective relay. If the switch is out of adjustment so that incorrect breaker status is reported to the relay, the relay may not operate when needed. Could proper operation of the auxiliary contacts be credited through in-service operation or the six-year breaker operation maintenance? 4. The term “calendar years” is used to define the maximum intervals. Does this mean that a six-year PM could go one-day shy of seven years? For example, if a six-year maintenance PM was last performed on 1/1/2010, it would be due on 1/1/2016. Could this allow until 12/31/2016 to complete the maintenance? 5. Table 1b, Row 14 (Row 2 on page 17): Under the “Level 2 Monitoring Attributes for Component,” UFLS/UVLS should be referenced instead of SPS. 6. Clarifications need to be made on testing requirements on trip contacts relative to microprocessor vs. EM relays. 7. There appears to be an inconsistency in the use of “check” vs. “verify” in the tables. 8. In battery maintenance table, we suggest that “cell/unit” be changed to “cell or unit.”
Response: Thank you for your comments.		

Organization	Yes or No	Question 1 Comment
1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. 3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. To the degree that in-service test-operating of the breaker also performs the specified maintenance on other portions of the Protection System, the entity should be able to document and "take credit" for it. 4. Your explanation of "6 Calendar Years" is correct. 5. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 through 1-5. 6. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1 and 1-5. 7. "Check" is not an element of the PSMP definition. This term has been replaced throughout the Tables with whatever term of the definition is relevant. **8.** The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4.		
PPL Supply	No	PPL Generation, on behalf of the entities listed above, has the following comments on the dc entries in these tables: 1. Table 1a, Table 1b, Table 1c- Station DC supply - Maintenance Activities - references substation batteries. For generators, shouldn't that reference be station battery? Substation implies an association strictly with transmission, not generation. 2. Station DC supply - verify Battery continuity. What is the technical basis for this requirement? Neither battery installation and operation instructions nor technical reviews explain the basis for how this verification is supposed to work. NERC's Protection System Maintenance: A Technical Reference does not address this requirement. The Frequently-Asked Questions provides some ways that this verification can be completed. However, one example is tied to the microprocessor battery chargers. If there is a technical basis for this requirement, it should be provided. 3. Condition based monitoring on station dc supply - it appears the Table 1b excludes any

Organization	Yes or No	Question 1 Comment
		condition based monitoring of the batteries because of the requirement for monitoring electrolyte level, individual cell state of charge, cell to cell and battery terminal resistance. Most monitoring equipment does not monitor those functions. 4. In general, the Tables are especially confusing in the dc system area. The "lines" overlap and need to be labeled, so they can be referenced in a maintenance document to show how the appropriate program can be followed. Each line should be separate in the function stated, so one can identify what has to be done to comply. 5. Provide examples of "non-battery-based dc equipment" that is covered under this standard. 6. For dc supply, the changes from the Sept. 2007 NERC "Protection System Maintenance", A Technical Reference seem too restrictive. The Sept. 2007 document contained a solid maintenance program. What is the basis for the change?
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. This has been corrected in the revision. 2. Please see the FAQ (I.5.B, I.5.C and I.5.D) 3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. 4. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. 5. The SDT has been advised that entities are considering or using technologies such as flywheels and fuel cells. Also, we have been told that some entities are using modern battery chargers without the battery. **6.** When developing the original technical reference, the SPCTF was not challenged to develop a complete, measurable Standard. The SDT used the original document as a starting point to develop actual requirements, etc.		
San Diego Gas & Electric	No	1. Proofing of CT circuits is not always trivial. Given this function is not presently being performed and documented by the company, a reasonable grace period would be

Organization	Yes or No	Question 1 Comment
		required to achieve compliance. The company believes present practice, such as verification that relay current inputs are not zero and that phases are balanced, is a reasonable indication individual CTs are functioning properly. 2. An entities protection system maintenance program is a Time Based Maintenance program. The protection system maintenance program describes the maintenance intervals and states that the protection system maintenance is triggered every 4 years. The maintenance program describes that the due date for compliance is 6 months past the trigger date to allow for planning and scheduling of the maintenance activity. Therefore the actual due date for the 4 year maintenance interval is 4 years and six months from the last maintenance completion date. The four year six month time based interval is within the six year maximum time based interval as required by PRC-005-2. Given the above, is the four year six month interval as described in the entities maintenance program compliant with PRC-005-2?
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3. The intervals remain as prescribed within the Standard and are designed to be effective, clear, and consistently monitored for compliance; the SDT is not prescribing or suggesting what measures an entity may take within their program to assure compliance. “Grace periods” within the Standard are not measurable, and would probably lead to persistently increasing intervals. However, an entity may establish an internal program with grace-period allowance, as long as the entire program (including grace periods) does not exceed the intervals within the Standard. Simply observing non-zero instrument transformer outputs may not be sufficient to determine that the values are acceptable. **2.** “Grace periods” within the Standard are not measurable, and would probably lead to persistently increasing intervals. However, an entity may establish an internal program with grace-period allowance, as long as the entire program (including grace periods) does not exceed the intervals within the Standard.		
Springfield Utility Board	No	SUB appreciates the effort to try to strike a balance between specificity around a specific standard and flexibility to meet the requirement under the standard. The maximum

Organization	Yes or No	Question 1 Comment
		allowable intervals don't seem unreasonable combined with the implementation schedule. However, it seems that the proposed changes stray toward a proscriptive set of maintenance that 1) does not allow for an alternate method of testing and 2) sets unrealistic testing requirements. For example, battery terminal to terminal testing is not feasible with all battery systems. This is a consistent message SUB has heard from others as well. First and foremost - a test or maintenance must be done for each device within the defined interval. With that in mind...SUB's preference would be that the maintenance activities focus on what specifically must be done for a device (may be type specific) vs. what could be done for a device for compliance (as an example of what an auditor could look for when conducting an audit) vs. alternative best-practices for testing and maintenance that the entity demonstrates constitutes as maintenance or test. With regard to the first (maintenance activities focus on what specifically must be done for a device) - it seems that this would apply to a limited number of devices With regard to the second (maintenance activities focus on what specifically can be done for a device) - it seems that this would apply broad number of devices and the list of what can be done should be broad to cover a range of different devices that provide the same function. With regard to the last (alternative best-practices for testing and maintenance that the entity demonstrates constitutes as maintenance or test), it would be helpful to have a mechanism outside the standard itself to either have a NERC technical group craft a series of criteria that must be met for an acceptable alternative maintenance or the entity document the criteria used to determine an adequate test and provide for a test that meets that set of criteria). It would be anticipated that these would fall under a minority of devices.
Response: Thank you for your comments.		

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 1 Comment</th></tr>
<tr><td colspan="3">The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 through 1-5.
In the draft Standard, the SDT is defining the basic parameters for an effective PSMP; the entity is required to develop its program with specific activities that would satisfy those basic parameters.</td></tr>
<tr><td>The Detroit Edison Company</td><td>No</td><td>Suggest that the interval for cell ohmic testing on VRLA batteries be changed to 12 months. Also, include ohmic testing of NiCad batteries at 18 mos. as an option.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The activity related to this interval is to verify various basic operating parameters. The SDT believes that extension of verification of these parameters beyond the interval within the Standard is inappropriate.</td></tr>
<tr><td>NorthWestern Corporation</td><td>No</td><td>Table 1a - Rows 3 & 4 (control and trip circuits) - add language in the Maintenance Activities - "except that verification does not require actual tripping of circuit breakers or interrupting devices"</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5.</td></tr>
<tr><td>We Energies</td><td>No</td><td>1. Table 1a, Protective Relays: Change 1st line to: “Test and calibrate if necessary the relays...”Table 1a, Protective Relays: 3rd line: Change “check the relay inputs...” to “verify the relay inputs...”. The term “check” is not defined, whereas “verify” is. Tables 1a & 1b We agree that six / twelve years is an acceptable interval for relay maintenance.
2. Table 1a & 1b, Control & Trip Circuits: The proposed addition to require tripping circuit breakers during Protection System maintenance is detrimental to BES reliability and should be removed. Ï
3. Generating unit protection system maintenance is done during scheduled outages. The high voltage breaker on a generating unit often remains energized to backfeed and supply station auxiliaries when the generator is offline. The proposed requirement will increase the amount of equipment requiring an outage for maintenance, and possibly</td></tr>
</table>

Organization	Yes or No	Question 1 Comment
		the length of the outage, resulting in significantly more equipment out of service as well as increased costs. This requirement also results in greater maintenance efforts and costs when there are redundant protection system equipment (breaker trip coils, lockout relays, etc), which is contrary to good practice and reliability. 4. Many of the breakers that We Energies, as the Distribution Provider, trips from its BES protection systems are not owned by We Energies and are owned by a separate transmission company. The trip testing and maintenance of the transmission company may not coincide with our relay maintenance testing program. The standard shall have allowances for the entity to ONLY test or maintain equipment that it OWNS! 5. Table 1a, Station dc supply: a. The activity to verify the state of charge of battery cells is too vague, and requires more specific action. We assume that the drafting committee is recommending specific gravity measurements. Specific gravity measurements have not been shown to an accurate indicator on state of charge. In addition, as shown in the nuclear power industry, there is no established corrective action that is taken based on specific gravity results (eg. Don't require a test where there is no acceptable corrective action). b. The activities to "verify battery continuity" and "check station dc supply voltage" are also vague and need to be more clearly specified what is intended. c. The 3 month time interval for battery impedance testing is too frequent. 18 month or annual testing is more appropriate. d. The 3 calendar year performance or service test is too frequent and will actually remove life from a battery and reduce reliability. Recommend capacity testing no more that every 5 years and more frequent test if the capacity is within 10% of the end of life or design. This is consistent with the nuclear power industry. 6. Table 1b, Station dc supply: Recommend a change or addition to Table 1b - Recommend a level 2 monitoring (not just a default to the level 1 maintenance activities)

Organization	Yes or No	Question 1 Comment
		which allows for the removal of quarterly "check" of electrolyte levels, DC supply voltage, and DC grounds - if station DC supply (charger) voltage is continuously monitored (eg. one should not have detrimental gassing of a battery if the float voltage of the battery is properly set and monitored). 7. Table 1a, Associated communications systems: The requirement to verify functionality every three months is excessive; verifying this every twelve months is adequate. 8. Tables 1a & 1b - Although the latest standard provided some additional clarification, more clarification is required on what maintenance / testing is ONLY required for UFLS/UVLS protection systems vs. BES protection systems (eg. UFLS / UVLS systems - Is a verification of proper voltage of the DC supply the only battery or DC supply required (eg. no state of charge, float voltage, terminal resistance, electrolyte level, grounds, impedance or performance test, etc.)?

Response: Thank you for your comments.

1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1. "Check" is not an element of the PSMP definition. This term has been replaced throughout the Tables with whatever term of the definition is relevant.
2. These devices contain "moving parts" which must be periodically exercised to remain reliable.
3. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. It is left to the the entity to determine how to align these requirements with operational concerns.
4. The SDT contends that "its Protection Systems" is synonymous with "Protection Systems that it owns."
5. a.The SDT is not specifically requiring specific gravity tests, although they may be one effective method of meeting the requirement. Another method is to measure the individual cell voltage. R4 establishes that the entity must initiate resolution of maintenance-correctable issues, so it IS necessary to correct problems that are found.

   b.The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. The SDT does not prescribe specific activities to satisfy the requirements, although some guidance may be found in the FAQ (II.5.B, II.5.C and

Organization	Yes or No	Question 1 Comment
II.5.D) and Supplementary Reference Section 15.4. c. The activity related to this interval is to verify basic operating parameters. The SDT believes that extension of verification of these parameters beyond the interval within the Standard is inappropriate. d. The SDT disagrees, and believes that a performance test at 3-year intervals is appropriate for Valve-Regulated Lead Acid batteries. A properly maintained battery, according to various credible references (from IEEE, EEI, EPRI, various manufacturers, etc.) can easily handle multiple deep discharges over its expected life. 6. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. 7. The SDT believes that the 3-month interval is proper for unmonitored communications systems. **8.** The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4.		
Hydro One Networks	No	1. Table 1a: a. V and I sensing to relays - 12 years? Why not perform this activity with maintenance activities associated with relay maintenance so that they line up? It would only be an incremental amount of work to perform this with associated relay maintenance work b. Removal of requirement for testing of unmonitored breaker trip coils? Is it really the intention of the SDT to remove a requirement that would drive the industry to install TC monitors on breakers to improve reliability? c. UFLS/UVLS DC control and trip circuits - Due to the distributed nature of this program, random failures to trip are not impactive to the overall operation of the UFLS protection. There should be no requirement to check the DC portion of these protections any more often than the DC circuit checks associated with that LV breaker. Since it is clear the requirement does not include the need to trip the breakers why the need to check the trip paths? Deletion of this requirement leaves the requirement to check only the relays and relay trip outputs from the protections every 6 years (or as often as the protective relay component type). d. Along the same lines as the above comment should the maintenance activities for

Organization	Yes or No	Question 1 Comment
		"UVLS and UFLS relays that comprise a protection scheme distributed over the power system" not be the same as "Protective Relays" 2. Table 1c: a. Level 3 attributes for "Associated communications systems" might better read "Evaluating the performance and quality of the channel as well as the performance of any interface to connected protective relays and alarming if the channel/protective relay connections do not meet performance criteria" b. We believe that some of the proposed maintenance intervals for station DC supply are too stringent and that they would not produce significant increase in reliability to justify associated incremental expenditure. For example we suggest that the following changes are considered:- The interval for electrolyte level check for all batteries except VRLAs and internal measured cell/unit Ohmic value for VRLAs be extended to 6 months instead of current time period of 3 months.- The performance or service capacity test of the VRLA battery banks to be extended from 3 years to 5 years.

Response: Thank you for your comments.

1. a. This activity CAN be performed with the relays (for example, every other relay interval) if the entity so desires.
   b. The Tables have been rearranged and considerably revised to simplify and improve clarity. Please see new Table 1-5. Specific to your comment, the SDT initially specified inspection of trip-coil monitoring functions at intervals of 3 calendar months, with tripping otherwise requried annually. This has been revised to simply require tripping at 6-calendar-month intervals.
   c. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5.
   d. This is an intentional difference between UFLS/UVLS and the remainder of the Protection Systems addressed within the Standard, because of the distributed nature of UFLS/UVLS and because these devices are usually tripping distribution system elements.
2. a. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3.

Organization	Yes or No	Question 1 Comment
b. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4.		
Arizona Public Service Company	No	The associated maintenance activities are too prescriptive. The activities needed to ensure the reliable service of the relay or device should be left up to the discretion of the utility.
Response: Thank you for your comments. The SDT disagrees. In the draft Standard, the SDT is defining the basic parameters for an effective PSMP; the entity is required to develop its program with specific activities that would satisfy those basic parameters.		
Manitoba Hydro	No	1. The monitoring attributes required to achieve level 2 monitoring of Station DC supply seem excessive. We are not aware of any other utilities doing automatic monitoring all 6 attributes required. In particular automatic monitoring of electrolyte level & battery terminal resistance does not seem practical. 2. There is inconsistency between Table 1 and the FAQ. In the Group by Monitoring Level section of the FAQ it indicates that a battery with low voltage alarm would be considered to have level 2 monitoring. 3. In Table 1C under the heading "Maximum Maintenance Interval" some of the entries are stated as being "Continuous". In the case of other maintenance activities the descriptor for Maintenance Interval indentifies the maximum period of time that may elapse before action must be taken. "Continuous" implies continuous action; however, in reality continuous monitoring enables no maintenance action to be taken until such time as trends indicate the need to do so. Therefore we recommend that where the maintenance interval be changed to read "Not Applicable".
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-4. 2. The FAQ has been modified. (See the examples in Section V.) **3.** The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 through 1-5.		

Organization	Yes or No	Question 1 Comment
MRO's NERC Standards Review Subcommittee (NSRS)	No	The NSRS feels additional changes are needed. 1. The functional testing requirement should be altered or removed as it increases the amount of hands-on involvement and the opportunity for human error related outages to occur, thereby introducing a greater risk to decrease system reliability. As noted on p. 8 in the supplementary reference document, "Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability." By removing circuits from service on the proposed timelines for functional testing, the chance for human error is greater than a misoperation from faulty wiring. Alternatively, entities may choose to schedule more planned outages to conduct their functional testing in order to limit the risk of unplanned outages resulting from human error. Under this scenario, more elements will be scheduled out of service on a regular basis, thereby reducing transmission system availability and weakening the system making it more challenging to withstand each subsequent contingency (N-1). Thus testing an intact system is more desirable than taking it out of service for testing. 2. While the SDT has included language in the draft standard to use fault analysis to complete maintenance obligations, in practicality, this option does not offer any relief to taking outages to perform functional tests. Nearly all BES circuit breakers are equipped with dual trip coils. Identifying which trip coil operated for a fault only covers the one trip coil. Functional tests would still be needed on the other. The likelihood of having multiple trips on a given line in the course of several years is very low. Given it can take a year to schedule some outages; planning maintenance with random faults is unpractical and will create unacceptable risk to compliance violations. A better approach is to use the basis in schedule A, but extend this to cover the entire protection schemes. The document should establish target goals for mis-operation rates (dependability and security). This would allow the utilities to develop cost effective programs to increase reliability. The utilities would have incentives to replace poorly performing communications systems; they would be able to quantify the value of upgrading relay systems.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comments. 1. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. The entity must determine how to align these requirements with operational concerns. **2.** Operational results, if desired by an entity, MAY be used to meet maintenance requirements to the degree that it verifies, etc., the relevant performance. Whether their use is effective for a specific entity is left to the entity to determine. “Maintenance correctable issues”, which may result in part from misoperations, are a part of using Attachment A to develop a performance-based PSMP.		
Tennessee Valley Authority	No	The requirement to measure internal ohmic values of the station dc supply batteries every 18 months is excessive. The interval should be 36 months. Our experience from performing our routine maintenance program including cell impedance testing at 3-year intervals has been that the program is fully adequate in monitoring bank condition.
Response: Thank you for your comments. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. The activity related to this interval is to verify various basic operating parameters. The SDT believes that extension of verification of these parameters beyond the interval within the Standard is inappropriate.		
Bonneville Power Administration	No	The requirements pertaining to dc control circuitry are confusing. 1. To start with, a definition or further explanation is required for the term “auxiliary contact”. Is this strictly a breaker “a” or “b” switch, or does this include lockout relay contacts, etc.? 2. Another confusing point is that the term trip circuit is used in several places throughout the tables, but it is not included in the definition of Protection System, where the term dc control circuitry is used. It is important to use consistent terminology throughout the definition and the standard. 3. The requirements for (dc) control circuits in Table 1a are fairly straightforward, but in

Organization	Yes or No	Question 1 Comment
		Table 1b control circuits are broken down into three parts: trip coils and auxiliary relays; trip circuits; and control and trip circuitry. It is very unclear exactly what each of these three parts includes. In Table 1c, control circuitry is covered as a single element. Please provide clarity to what is included in each part of a control circuit in Table 1b and the monitoring attributes of each. Also, please be consistent in the treatment of control circuits throughout the three tables. 4. Table 1a, SPS, BPA does not understand the following segment of this paragraph "The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval." In one sentence, it says you can test a SPS in segments - and in the next sentence it says you have to verify the grouped output control action at least once within the specified time interval. It seems that the sentences contradict themselves. 5. Table 1b, Control and trip circuitry - "Monitoring of the continuity of breaker trip circuits along with the presence of tripping voltage supply all the way from relay terminals (or from inside the relay) through to the trip coil(s)..." To monitor the trip path as proposed in this Standard would cost some serious time and $$. 6. BPA does not believe there is a way to meet level two monitoring for batteries. In addition, some of the maintenance tasks need to be defined:- monitoring the electrolyte level is not commercially available.- the state of charge of each individual cell may need to be better defined. There are means to verify the state of charge of the entire bank, but not each individual cell. 7. Since a device to provide level 2 monitoring is not commercially available, we would be forced to follow level 1 maintenance guides, which would require maintenance of communication batteries every three months. Many of these batteries are not accessible during 9 months of the year except via snow-cat or helicopter. We currently monitor for some of the level 2 requirements, but not all. Our current practices of monitoring and yearly maintenance supplemented by opportunity inspections have

Organization	Yes or No	Question 1 Comment
		successfully identified problems before we lost DC power to any of our communication facilities. VRLA type batteries: - battery continuity needs to be defined. 8. In regards to the maximum allowable intervals; the frequency with which BPA performs the 18 month maintenance tasks as prescribed in the standard are on a 24 month interval along with visual inspections and voltage measurements weekly to bi-weekly. BPA has seen success with this maintenance program with the ability to identify suspect cells or entire banks with adequate time to perform corrective actions such as repairs or replacements. BPA also does not perform routine capacity testing, this is an as required maintenance task to confirm/validate our other test results if needed. Our suggestion would be to extend the maintenance intervals beyond 18 months, and to provide some clarity on the above items.

Response: Thank you for your comments.

1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. Please see Section 15.3 of the Supplementary Reference Document and the FAQ (II4.E.).
2. The Tables have been rearranged and considerably revised to improve clarity and consistency. Please see new Table 1-5.
3. The Tables have been rearranged and considerably revised to improve clarity and consistency. Please see new Table 1-5.
4. The Tables have been rearranged and considerably revised to improve clarity and consistency. Please see new Table 1-5.
5. The Tables have been rearranged and considerably revised to improve clarity and consistency. Please see new Table 1-5.
6. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. Also, the SDT believes that there are devices available to monitor electrolyte levels.
7. The FAQ (II.5.K) advises that “communications system batteries” are not “station batteries” and are maintained with the communications systems.
8. The activity related to this interval is to verify various basic operating parameters. The SDT believes that extension of verification of these parameters beyond the interval within the Standard is inappropriate.

Organization	Yes or No	Question 1 Comment
Public Service Enterprise Group ("PSEG Companies")	No	The SDT is to be commended for the work and details included in the most recent draft revision. The standard - with associated references is easier to interpret. 1. The sections on DC supply are too restrictive. Quartile checks of VLA electrolyte levels for unmonitored systems is reasonable, however the option of checking the electrolyte levels and voltages with less frequency is not an option with systems that have voltage alarm notification and ground detection monitoring alarm notification unless all level 2 attributes are followed. The level 2 monitoring attributes are too comprehensive to allow for a suggested alternative less restrictive interval of 6 months to a year. Suggest there be an additional option for level 2 monitoring that includes voltage level and ground alarms with a 6 month maintenance activity interval. 2. The perception of table 1a page 12 for station DC supply - “used for UVLS and UFLS” is a maintenance activity to verify proper DC supply voltage when the UVLS and UFLS system is maintained. This is the only DC supply maintenance activity for those applications and the other more rigorous maintenance activities do not apply? If this is a correct interpretation specifically list that as such in the maintenance activity description (State the other DC supply maintenance activities are not applicable for UVLS and UFLS). The maintenance intervals for station DC supply for level 1 and 2 monitoring does not appear to be consistent and is somewhat confusing. A battery system with level 2 monitoring attributes for components has intervals of 6 years, and then in next section states that no level 2 attributes are defined - use level 1 maintenance activities. Suggest that all DC supply / batteries be broken out all be included in one separate - stand alone table with varied maintenance requirements based on monitoring attributes. 3. The maintenance activities shown on table 1b on page 19 for Station DC supply is intended for VLA batteries? If so add that in component definition. 4. For DC systems that use a storage battery, suggest that chargers be eliminated as other required maintenance activities will expose any problems with the charger. 5. The requirements of performing a capacity test every 6 years during the initial service

Organization	Yes or No	Question 1 Comment
		life of a VLA battery in addition to the other maintenance activities are too restrictive and will cause extensive outages of the affected equipment. Suggest that this frequency be extended to 10 years for VLA batteries for the first iteration if all the other maintenance activities are followed. Failure rate of VLA in first 10 years is extremely low. Other maintenance activities will expose significant issues.
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. 2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. 3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. 4. If the charger fails, the battery will quickly discharge via normal dc loads, and be unable to adequately serve the Protection System. **5.** The SDT disagrees, and believes that a capacity test at 6-year intervals is appropiate for Vented Lead Acid batteries.		
US Bureau of Reclamation	No	1. There is no reliability based justification to alter the standards to include allowable intervals. 2. The intervals prescription for performance based PSMP virtually eliminates the capability of smaller utilities who do not have a large equipment database to justify a performance based system that may be sound based on their experience. This overly prescriptive approach should be eliminated and return to allowing utilities to justify their programs. The standard should return to addressing real reliability impacts as required by law. This would be to develop a maintenance required which identifies that if it is shown that an event in which reliability is impacted by the utilities PSMP, as evidenced by disturbance reports, the utility would be required to submit to the RRO a corrective action plan which addresses how the PSMP will be revised and when compliance with that PSMP is to be achieved. 3. Finally, the standard presumes that components within a BES Element will cause a reliability impact to the BES. In numerous meeting with NERC and WECC it was

Organization	Yes or No	Question 1 Comment
		emphasized that a reliability impact has been described as causing cascading outages or causing loss of service to load above a certain magnitude. The BES has an ability to absorb element outages resulting from a variety of causes without impact load or resulting in cascading outages.
Response: Thank you for your comments. 1. FERC Order 693 directs NERC to establish maximum allowable intervals. 2. Small entities are permitted to aggregate their components with similar components of other entities to meet the component populations, as long as the programs are (and remain) similar – see Section 9 of the Supplementary Reference, the FAQ (IV.3.A) and the associated footnote to Attachment A. Decreasing the component population below the requirements of Attachment A will result in an unsound program due to component populations that are not statistically significant. **3.** The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff.		
Dynegy Inc.	No	We agree with all proposed intervals in Tables 1a, 1b, and 1c except the 3 calendar month interval for Associated Communication Systems in Table 1a. We suggest using a 1 year interval because all other elements of the Protection System are being verified a minimum of every 3 years. Therefore, we believe annual verification of Associated Communication Systems is sufficient.
Response: Thank you for your comments. The SDT believes that the 3-month interval is proper for unmonitored communications systems.		
Pacific Northwest Small Public Power Utility Comment Group	No	We agree with most of the changes from the last draft. However, the phrase “Verify Battery cell-to-cell connection resistance” has entered the table where it did not exist before. On some types of stationary battery units, this internal connection is inaccessible. On other types the connections are accessible, but there is no way to repair them based on a bad reading. And bad cell-to-cell connections within units will be detected by the other required

Organization	Yes or No	Question 1 Comment
		tests. This requirement will cause entities to scrap perfectly good batteries just so this test can be performed, with no corresponding increase in bulk electric system reliability while taking an unnecessary risk to personnel and the environment. And because buying battery units composed of multiple cells allows space saving designs, entities may be forced to buy smaller capacity batteries to fit existing spaces. This may end up having a negative effect on reliability. Suggest substituting "unit-to-unit" wherever "cell-to-cell" is used in the table now.
Response: Thank you for your comments. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. This element of the table has been modified to state, "Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)" to address this comment.		
PNGC Power	No	We agree with most of the changes from the last draft. However, the phrase "Verify Battery cell-to-cell connection resistance" has entered the table where it did not exist before. On some types of stationary battery units, this internal connection is inaccessible. On other types the connections are accessible, but there is no way to repair them based on a bad reading. And bad cell-to-cell connections within units will be detected by the other required tests. This requirement will cause entities to scrap perfectly good batteries just so this test can be performed, with no corresponding increase in bulk electric system reliability while taking an unnecessary risk to personnel and the environment. And because buying battery units composed of multiple cells allows space saving designs, entities may be forced to buy smaller capacity batteries to fit existing spaces. This may end up having a negative effect on reliability. Suggest substituting "unit-to-unit" wherever "cell-to-cell" is used in the table now.
Response: Thank you for your comments. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. This element of the table has been modified to state, "Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)" to address this comment.		
FirstEnergy	No	We support most of the maintenance activities detailed in the Tables, but question the

Organization	Yes or No	Question 1 Comment
		verification of battery cell-to-cell resistance. On some types of battery units, this internal connection is inaccessible. We suggest substituting "unit-to-unit" in place of "cell-to-cell".
Response: Thank you for your comments. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. This element of the table has been modified to state, “Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)” to address this comment.		
Florida Municipal Power Agency	No	1. Will the Standard Introduce Technical Feasibility Exceptions to PRC Standards? A large proportion of the batteries (as high as 50% as reported by some SMEs) are not able to accommodate all of the tests prescribed in the draft standard. The phrase “Verify Battery cell-to-cell connection resistance” has entered the table where it did not exist before. On some types of stationary battery units, this internal connection is inaccessible. On other types the connections are accessible, but there is no way to repair them based on a bad reading. And bad cell-to-cell connections within units will be detected by the other required tests. This requirement will cause entities to scrap perfectly good batteries just so this test can be performed, with no corresponding increase in bulk electric system reliability while taking an unnecessary risk to personnel and the environment. And because buying battery units composed of multiple cells allows space saving designs, entities may be forced to buy smaller capacity batteries to fit existing spaces. This may end up having a negative effect on reliability. Suggest substituting “unit-to-unit” wherever “cell-to-cell” is used in the table now. 2. The Standard Reaches Beyond the Statutory Scope of the Reliability Standards As written, the standard requires testing of batteries, DC control circuits, etc., of distribution level protection components associated with UFLS and UVLS. UFLS and UVLS are different than protection systems used to clear a fault from the BES. An uncleared fault on the BES can have an Adverse Reliability Impact and hence; the focus on making sure the fault is cleared is important and appropriate. However, a UFLs or UVLS event happens after the fault is cleared and is an inexact science of trying to automatically restore supply and demand balance (UFLS) or restore voltages (UVLS) to acceptable

Organization	Yes or No	Question 1 Comment
		levels. If a few UFLS or UVLS relays fail to operate out of potentially thousands of relays with the same function, there is no significant impact to the function of UFLS or UVLS. Hence, there is no corresponding need to focus on every little aspect of the UFLS or UVLS systems. Therefore, the only component of UFLS or UVLS that ought to be focused on in the new PRF-005 standard is the UFLS or UVLS relay itself and not distribution class equipment such as batteries, DC control circuitry, etc., and these latter ought to be removed from the standard. In addition, most distribution circuit are radial without substation arrangements that would allow functional testing without putting customers out of service while the testing was underway, or at least without momentary outages while customers were switched from one circuit to another. Therefore, as written, we would be sacrificing customer service for a negligible impact on BES reliability.
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. This element of the table has been modified to state, “Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)” to address this comment. **2.** The Standard addresses UFLS and UVLS to the degree that they are installed per NERC Standards, even though entities may choose to install them on distribution systems.		
NERC Staff	Yes	
PacifiCorp	Yes	
WECC	Yes	Compliance agrees with the changes as they add clarity though the Tables do not define what is actually required to demonstrate compliance without reading the Supplementary Reference and the FAQs.
Response: Thank you for your comments. The Measures do provide discussion of what is required to demonstrate compliance.		

Organization	Yes or No	Question 1 Comment
The United Illuminating Company	Yes	In general yes. There are concerns with verifying cell-to-cell resistance in Batteries. On some battery sets this is not possible to do.
Response: Thank you for your comments. This element of the table has been modified to state, “Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)” to address this comment.		
South Carolina Electric and Gas	Yes	Please provide clarity on why Table 1b for “Station dc supply” has a double entry that appears to be contradictory. The table provides monitoring attributes for a maximum maintenance interval of 6 calendar years and the next row says to refer to level 1 maintenance activities.
Response: Thank you for your comments. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4.		
ReliabilityFirst Corp.	Yes	1. The SDT has made significant and worthwhile changes to these tables. However, these tables still seem overly complex and should be simplified. One possibility would be to eliminate Table 1c and use Table 1b for those components that meet certain monitoring attributes. 2. There are some errors in Table 1a in rows 5 and 6. In row 5 in the component column the word “contact” is missing. In the same row in the third column, there is an extra period. In row 6 in the third column, “circuit” should be “circuits” as in the other rows. 3. The maintenance intervals seem to give preference to solid-state outputs but there is no evidence given that these are truly more reliable than an electromechanical trip at least not sufficient to double the maintenance interval.
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 through 1-5.		

Organization	Yes or No	Question 1 Comment
2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 through 1-5. **3.** The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1.		

2. **The SDT has included VRFs and Time Horizons with this posting. Do you agree with the assignments that have been made? If not, please provide specific suggestions for improvement.**

Summary Consideration: Many commenters disagreed with various VRFs as specified in the draft Standard. The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High. Some comments were offered regarding Time Horizons, resulting in modification of the Time Horizons for both R3 and R4 from Long-Term Planning to Operations Planning.

Organization	Yes or No	Question 2 Comment
PPL Supply		No comment.
Xcel Energy		No comments
SERC Protection and Control Sub-committee (PCS)		The SERC PCS expresses no opinion on this question.
San Diego Gas & Electric	No	
The Detroit Edison Company	No	
Black Hills Power	No	
The United Illuminating Company	No	The VRF for R1 should be Low. It is administrative to create an inventory list. If R1 failed to be executed but the other requirements wee executed fully then the BES would be

Organization	Yes or No	Question 2 Comment
		properly secured. Compare this against the scenario of performing R1 but failing to perform the other tasks; in which case the BES is at risk. UI recognizes that the SDT considers the inventory as the foundation of the PSMP but it is not the element of the PSMP that provides for the level of reliability sought. R1 should be VRF Low and R2 thru R4 VRF is Medium. UI agrees with the Time Horizon.
Response: Thank you for your comments. The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High.		
JEA	No	1. What role with the Supplementary Reference and FAQ play with reference to the proposed standard? We have a concern that the standard will stand-alone and not include the interpretations, examples and explanations that are needed to properly apply these values in a compliance environment. There needs to be a method to include the FAQ and Supplementary Reference. 2. The method will also need to allow for future modifications as the standard is revised, etc.
Response: Thank you for your comments. 1. The Supplementary Reference and FAQ documents provide supporting discussion, but are not part of the Standard. The SDT intends that these be posted as reference documents, accompanying the Standard. **2.** The SDT intends that these documents be updated as the Standard is revised, such that they continue to be relevant to the application of the Standard.		
FirstEnergy	No	Although we agree that Requirement 1 is important because it establishes a sound PSMP, a HIGH VRF assignment is not appropriate and it should be changed to LOWER. By definition, a requirement with a LOWER VRF is administrative in nature, and documentation of a program is administrative. Assigning a LOWER VRF to R1 is more logical since R4, which is the requirement to implement the PSMP, is assigned a MEDIUM VRF because, if violated, it could directly affect the electrical state or the capability of the bulk electric

Organization	Yes or No	Question 2 Comment
		system. Additionally, revising the VRF to LOWER would provide a consistent assignment to a VRF on a similar requirement in the proposed FAC-003-2 standard.
Response: Thank you for your comments. The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High. For a VRF to be classified as "Lower" it must be administrative, and none of the requirements in this standard are 'administrative'.		
Pepco Holdings, Inc. - Affiliates	No	An explanation is needed to justify why the VRF for R1 of the PSMP is High whereas the implementing and following of the PSMP is Medium, R2, R3 & R4.
Response: Thank you for your comments. The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High.		
American Transmission Company	No	ATC disagrees with the VRFs as specified in the standard. R1 VRF would more likely be classified as "medium" and R2 through R4 should be classified as a "High" VRF. ATC is O.K. with the Time Horizons specified.
Response: Thank you for your comments. The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High.		
Constellation Power Generation	No	Constellation Power Generation questions why the VRF for R1 is High while all other requirements are Medium. This VRF should be changed to Medium to follow suit with the other requirements.
Response: Thank you for your comments. The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High.		
Florida Municipal Power Agency	No	R1, R2 and R3 are administrative in nature and ought to be a Low VRF, not a High or Medium VRF. R4 is doing the actual maintenance and testing and ought to be the highest VRF in the standard. Medium VRF is appropriate for R4.

Organization	Yes or No	Question 2 Comment
Response: Thank you for your comments. The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High.		
ReliabilityFirst Corp.	No	R4 is the implementation of a maintenance program which is extremely important. Effective operation of the BES is so dependent on adequate maintenance that requirement R4 warrants a High VRF. It seems that requirement R3 may actually be better categorized as having an Operations Assessment Time Horizon as the entity needs to review events to analyze the adequacy of maintenance periods.
Response: Thank you for your comments. The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High. The SDT agrees with the suggestion to change the R3 Time Horizon and has assigned an Operations Planning Time Horizon.		
BGE	No	See comments under 7 regarding the ambiguity of R1.1. A high VRF for some interpretations of R1.1 may not be reasonable. A program may be structured so that sufficient maintenance to ensure reliability is taking place even though a specific component is not identified. Contrasting the high VRF for R1 with the medium VRF for R4 seems backwards.
Response: Thank you for your comments. The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High.		
MRO's NERC Standards Review Subcommittee (NSRS)	No	The NSRS disagrees with the VRFs as specified in the standard. R1 VRF would more likely be classified as "medium" and R2 through R4 should be classified as a "High" VRF.
Response: Thank you for your comments. The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High.		

Organization	Yes or No	Question 2 Comment
US Bureau of Reclamation	No	The Time Horizons are too narrow for the implementation of the standard as written. The SDT appears to have not accounted for the data analysis associated with performance based systems. The data collection, analysis, and subsequent decisions associated development of a maintenance program and its justification do not occur overnight especially with larger utilities. In addition, this new standard will require complete rewrite of maintenance programs. The internal processes associated with these vary based on the size of the utility. Since this standard is so invasive into the internal decisions concerning maintenance, the standard should allow at least 18 months for entities to rewrite their internal maintenance programs to meet the requirements and 18 months to train the staff and implement the new program.
Response: Thank you for your comments. The SDT has reviewed the time horizons, and feels that R1 and R2 are properly assigned a Long-Term Planning Time Horizon, as the activities to develop a program and to determine the monitoring attributes of components are performed within the related time period. The SDT has assigned an Operations Planning Time Horizon to R3 and R4, as some of the related activities must take place within 1-year intervals.		
Ameren	No	The VRF for R1 should be Medium because the failure to do so is commensurate with the risks of the other requirements. For example, failing to establish a PSMP for some portion of the entity's components could lead to their maintenance not meeting this standard; this is the same is establishing the PSMP and then not performing the maintenance per the standard.
Response: Thank you for your comments. The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High.		
Indeck Energy Services	No	The VRF's are highly arbitrary because they treat all registered entities and all protective systems alike. They're not. For example, under-frequency relays for generators protect the equipment needed to restore the system after a blackout. The under-frequency load relays prevent a cascading outage. As discussed at the FERC Technical Conference on Standards Development, the goal of the standards program is to avoid or prevent

Organization	Yes or No	Question 2 Comment
		cascading outages--specifically not loss of load. That would make under-frequency load relays more important to prevent cascading outages.
Response: Thank you for your comments. The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High. The risk to the system is independent of entity size. VSLs have been modified where necessary to make them independent of size of entity.		
Springfield Utility Board	No	1. Time horizons for implementation seem adequate and SUB appreciates the attention to putting together a reasonable but assertive implementation plan. 2. The Violation Risk Factors are problematic. With all due respect, it seems that NERC still operates in a "BIG UTILITY" mind set. There are "PROTECTION SYSTEMS" and there are "Protection Systems" - some Protection Systems may significantly impact system reliability and others may not. This not promote reliability in that if an entity was thinking about installing a minor system or installing an improvement that enhances reliability (but is not required) that it might back away because of the risk associated with somehow being out of compliance. Reliability runs the risk of being diminished through the standards approach. SUB suggests stepping back and putting more granularity on VRFs and there needs to be more perspective on the purpose of the device when arriving at a risk factor. Perhaps a voltage threshold could be attached to the VRFs. For example language could be added to say "For Elements at 200kV and above, or for Critical Assets, the risk factor is higher" and "For Elements operating at 100kV and above, the risk factor is medium" and "For Elements below 100kV, the risk factor is lower" In SUB's view, a discussion on VRF's needs to coupled with Violation Severity Levels. SUB discusses VRF's later in this comment form. SUB would be supportive of a Medium VRF designation if there were a more balanced VLF structure (please refer to the comments of VLFs)
Response: Thank you for your comments. The SDT has reconsidered the VRFs in accordance with the guidance provided by NERC and FERC, and the Standard has been modified to assign the VRFs as R1 – Medium, R2 – Medium, R3 – Medium, and R4 – High.		

Organization	Yes or No	Question 2 Comment
According to the current Reliability Standards Development Procedure, each Requirement is assigned one (and only one) VRF.		
Manitoba Hydro	No	Time horizons to change from present 6 months to 3 months maintenance time intervals within proposed implementation time period is not realistic.
Response: Thank you for your comments. The options for Time Horizon are Long-Term Planning, Operations Planning, Same-Day Operations, Real-Time Operations, and Operations Assessment. The SDT has reviewed the Time Horizons, and feels that R1 and R2 are properly assigned a Long-Term Planning time horizon, as the activities to develop a program and to determine the monitoring attributes of components is performed within the related time period. The SDT has assigned an Operations Planning Time Horizon to R3 and R4, as some of the related activities must take place within 1-year intervals.

Y-W Electric Association, Inc.	Yes	
PacifiCorp	Yes	Agree with the exception that the time horizon for implementation needs to recognize that documentation for maintenance tasks performed prior to this standard may not match current requirements and there should be no penalty for this.
Response: Thank you for your comments. The Implementation Plan needs to address the concerns expressed.		
Nebraska Public Power District	Yes	Please provide an example of how the compliance percentage will be calculated for the implementation plan.
Response: Thank you for your comments. The SDT does not understand how this comment relates to the VRFs or to the Time Horizons.		

3. **The SDT has included Measures and Data Retention with this posting. Do you agree with the assignments that have been made? If not, please provide specific suggestions for improvement.**

Summary Consideration: Many commenters expressed concern about the data retention requirements for two full maintenance intervals, and the SDT responded that this is consistent with today's expectations of many Compliance Monitors. Other commenters were concerned about data retention over the transition from PRC-005-1 to two full maintenance intervals for PRC-005-2, and the SDT offered advice that, until two maintenance cycles have been experienced under PRC-005-2, the program and associated documentation for PRC-005-1 will still be relevant.

Comments were offered that "on-site" audits as expressed in the Data Retention Section (item 1.3 under Compliance) are not relevant for small entities which are not audited on-site; the SDT agrees and changed the term to "scheduled" audits.

Several commenters offered suggestions relative to the Measures, resulting in changes to all four Measures. The SDT removed the detailed Protection System definition from Measure M1, inserted "Distribution Provider" in Measure M2, and made changes to consistently use "shall" rather than "will" or "should" throughout all the Measures.

Organization	Yes or No	Question 3 Comment
WECC		1. Compliance agrees with the measures. 2. Compliance recommends making the Supplementary Reference part of the standard and that it be referenced appropriately in Table 1a, 1b, 1c and Attachment A. 3. Compliance does not agree with the Data Retention as provided in the draft. In order for an entity to demonstrate that they have maintained system protection elements within their defined intervals retention of documentation will be required for many years.

Organization	Yes or No	Question 3 Comment
		This is in order to establish bookends for the maintenance interval. Maintenance intervals commonly span 5 years or more. Entities should be required to retain data for the entire period of the maintenance interval. Data Retention should be changed to: The Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generation Owner that owns a generation Protection System, shall retain evidence of the implementation of its Protection System maintenance and testing program for a minimum of the duration of one maintenance interval as defined in the maintenance and testing program.
Response: Thank you for your comments. 1. Thank you. 2. This document provides supporting discussion, but is not part of the Standard. The SDT intends that it be posted as a Reference Document, accompanying the Standard. As established in SDT Guidelines, the Standard is to be a terse statement of requirements, etc, and is not to include explanatory information like that included in the Supplementary Reference Document. **3.** The SDT believes that the modification suggested in the comment is not sufficient to demonstrate compliance. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one. The SDT has specified the data retention in the posted Standard to establish this level of documentation.		
Xcel Energy		No comments
San Diego Gas & Electric	No	
The Detroit Edison Company	No	
Ameren	No	1) M2 incorrectly excludes Distribution Provider. 2) For those components with numerous cycles between on-site audits, retaining and

Organization	Yes or No	Question 3 Comment
		providing evidence of the two most recent distinct maintenance performances and the date of the others should be sufficient. If an entity misses a required maintenance, that results in a self report. We are subject to spot audits and inquiries at any time between on-site audits as well. 3) For those components with cycles exceeding on-site audit interval, retaining and providing evidence of the most recent distinct maintenance performance and the date of the preceding one should be sufficient. Auditors will have reviewed the preceding maintenance record. Retaining these additional records consumes resources with no reliability gain. 4) FAQ II 2B final sentence states that documentation for replaced equipment must be retained to prove the interval of its maintenance. We oppose this because: the replaced equipment is gone and has no impact on BES reliability; and such retention clutters the data base and could cause confusion. For example, it could result in saving lead acid battery load test data beyond the life of its replacement.
Response: Thank you for your comments. 1. Distribution Provider has been added to Measure M2. 2. The SDT understands that Compliance Monitors will usually wish to review data to review program performance back to the preceding on-site audit. **3.** The SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one. The SDT has specified the data retention in the posted Standard to establish this level of documentation. The SDT understands that Compliance Monitors are currenlty requesting data on retired components to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance), and believes that this suggestion in the FAQ is appropriate.		
Northeast Power Coordinating Council	No	1. Clarification is needed for “on-site audit” - does it include audits by any of the following - NPCC/NERC/FERC. Several small entities do not have on-site audits and participate in

Organization	Yes or No	Question 3 Comment
		off-site audits. Hence, suggest deleting “on-site” from the requirement. 2. Further clarification is required to the Data Retention section to coordinate with the statement in FAQ (Section IV.d p. 22 redline). Suggest the following revised Data Retention requirement consistent with the statement and example given in FAQ:”The Transmission Owner, Generator Owner, and Distribution Provider shall each retain at least two maintenance test records or statistical data to demonstrate compliance with test interval required for each distinct maintenance activity for the Protection System components. The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records.”
Response: Thank you for your comments. 1. We have modified “on-site” to “scheduled” to address this comment. **2.** The SDT was unable to locate the discussion from the comment within the FAQ.		
Constellation Power Generation	No	Constellation Power Generation does not agree with the proposed data retention section. Retaining and providing evidence of the two most recent performances of each distinct maintenance activity should be sufficient. For entities that have not been audited since June of 2007, having to retain evidence from that date to the date of an audit could contain numerous cycles, which is cumbersome and does not improve the reliability of the BES.
Response: Thank you for your comments. For shorter-interval activities (such as those with quarterly intervals), the SDT understands that Compliance Monitors are currently requesting data to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance) or for the duration specified in a standard.		
JEA	No	Data retention becomes a complex issue for maintenance intervals of 12 years where the last two test intervals are required to be kept, i.e. 24 years. It would seem much more reasonable to set a limit of two test intervals or the last regional audit, not having to keep some 24 years of documentation with maintenance systems changing and archival records

Organization	Yes or No	Question 3 Comment
		somewhat problematic to keep.
Response: Thank you for your comments. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one. The SDT has specified the data retention in the posted standard to establish this level of documentation.		
Public Service Enterprise Group ("PSEG Companies")	No	Data retention for battery capacity test should be most recent performance, not last 2. The other maintenance activities documentation with one iteration of capacity test is sufficient documentation
Response: Thank you for your comments. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one, as well as data to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted Standard to establish this level of documentation.		
PacifiCorp	No	Data retention requirements need to be modified. The need to maintain records of two previous tasks is excessive, one should be adequate. Per the two previous task requirements an entity may need to maintain records for 35 years.
Response: Thank you for your comments. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one, as well as data to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted Standard to establish this level of documentation.		
Progress Energy Carolinas	No	M2 incorrectly excludes Distribution Provider.
Response: Thank you for your comments. Measure M2 has been modified to add “Distribution Provider.”		
Duke Energy	No	M4 states that entities shall have evidence such as maintenance records or maintenance summaries (including dates that the components were maintained). We would like to see

Organization	Yes or No	Question 3 Comment
		M4 revised/expanded to explicitly include the FAQ Section IV 1.B information which states that forms of evidence that are acceptable include, but are not limited to: o Process documents or plans o Data (such as relay settings sheets, photos, SCADA, and test records) o Database screen shots that demonstrate compliance information o Diagrams, engineering prints, schematics, maintenance and testing records, etc. o Logs (operator, substation, and other types of log) o Inspection forms o U.S. or Canadian mail, memos, or email proving the required information was exchanged, coordinated, submitted or received o Database lists and records o Check-off forms (paper or electronic) o Any record that demonstrates that the maintenance activity was known and accounted for.
Response: Thank you for your comments. The Standard Development Procedure requires that Measures provide some examples of evidence, but does not require an exhaustive list. The SDT did add "check-off lists" and "inspection records."		
Indeck Energy Services	No	Measure 1 is complete overkill for a small generating facility. The maintenance program is to inspect and test the equipment within the intervals. A qualified contractor applies industry standard methods to maintain the equipment. Trying to have each entity define the maintenance program down to the component level does not improve reliability.
Response: Thank you for your comments. A definition of "Component" has been added to the draft PRC-005-2 Standard to help explain how "component" can be characterized.		

Organization	Yes or No	Question 3 Comment
PPL Supply	No	1. Measurers M1 - requires having a maintenance program that addresses control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers. Some generators do not own this equipment to the circuit breaker or other interrupting devices. The requirement should be to maintain and test the equipment owned by the generator. 2. Data Retention 1.3 references on-site audits. Entities registered as GO and GOP are not audited on-site.
Response: Thank you for your comments. 1. The SDT believes that "its Protection Systems" in Requirement R1 is synonymous with "Protection Systems that it owns" and declines to modify the Standard to address this comment. **2.** We have modified "on-site" to "scheduled" to address this comment.		
Arizona Public Service Company	No	The change to the Protection System definition and establishing a PSMP with prescriptive maintenance activities relative to the voltage and current sensing devices has created a situation where data from original or prior verification not being available or not at the interval to meet the data retention requirement. Although, methods of determining the integrity of the voltage and current inputs into the relays were used to ensure reliability of the devices meets the utilities requirements, they may not meet the interval requirement and would then be considered a violation due to changes in the standard. Recommend a single exemption of the two recent most recent performances of maintenance activities to the most recent performance of maintenance activity in the first maintenance interval for this component due to the long maintenance interval, the changes in the standard definitions and the prescriptive maintenance activities.
Response: Thank you for your comments. The SDT believes that Compliance Monitors will assess compliance for activities performed before the effective date of this Standard using the program that you had in place previously.		

Organization	Yes or No	Question 3 Comment
American Electric Power	No	1. The measure includes the entire definition of "Protection System". Remove the definition from the measure and let the definition stand alone in the NERC glossary. 2. 1.3 Data Retention This calls for past 2 distinct maintenance records to be kept. Since UFLS interval can be 12 years, this would mean that we would need to keep records for 24 years. This is not realistic and consideration should be given to choosing a reasonable retention threshold.
Response: Thank you for your comments. 1. Measure M2 has been modified as suggested. **2.** In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one, as well as data to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted Standard to establish this level of documentation.		
Springfield Utility Board	No	The measures do not seem unreasonable. However the data retention states that documentation must exist for the two most recent performances of each maintenance activity. Stepping back, there is an implementation schedule that is designed to bring all devices into compliance with ONE maintenance or test within (SUB's understanding is) 6 years. There may not be documentation for more than one activity. Further, new or replacement components won't have more than one activity for a number of years. The data retention schedule, left unchanged, will promote non-compliance because it is impossible to have two records when only one may possibly exist. Rather than promote a culture of compliance, the standard promotes a culture of non-compliance by creating an standard that cannot be met. The FAQ addresses this issue, but the Data Retention language seems to be less clear. SUB suggests that the Data Retention language be clear that new components that do not replace existing components may have only one record for maintenance if only one maintenance of the component could possibly exist. SUB suggests that the Data Retention language also be clear that for new components that

Organization	Yes or No	Question 3 Comment
		replace existing components, that the Data Retention requirement reflect that the entity needs to retain the last test for the pre-existing component and the test for the new component (for a total of two tests).
Response: Thank you for your comments. First of all, the Data Retention presumes a stable Standard that has been in effect. Further, the SDT believes that Compliance Monitors will assess compliance for activities performed before the effective date of this Standard using the program that you had in place previously. Therefore, the documentation for your program under PRC-005-1 (whatever it may have been) will serve as your "second interval" documentation until supplanted by new PRC-005-2 records.		
US Bureau of Reclamation	No	The measures M2, M3, and M4 are redundant to measure M1. Either eliminate M1 or M2 through M4. The entity must provide documentation of its maintenance program in M1 irrespective of the type used. As previously mentioned there is not reliability based justification for the documentation required. The Entity should be afforded the freedom to make intelligent maintenance choices based on innumerable factors. These choices will be reviewed if a reliability impact is determined to be related to the choices.
Response: Thank you for your comments. The NERC Reliability Standard Development Procedure establishes that each individual requirement will have its own Measure. Additionally, the four Measures are NOT redundant – Measure M1 addresses "having a program," Measure M2 addresses "monitoring attributes to use extended intervals in the Tables," Measure M3 addresses "criteria for a performance-based program," and Measure M4 addresses "implementation of the program."		
American Transmission Company	No	The NERC standard assigns a retention period for the two most recent performances of maintenance activity which implies two intervals of documentation be maintained. ATC does not agree that requiring all data for two full cycles is warranted. The volume and length of data retention is unreasonable. ATC recommends that the entity retain the last test date with the associated data, plus the prior cycle test date only without retaining the test data. ATC agrees with assignment of the measures.
Response: Thank you for your comments. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding		

Organization	Yes or No	Question 3 Comment
one. The SDT has specified the data retention in the posted Standard to establish this level of documentation.		
MRO's NERC Standards Review Subcommittee (NSRS)	No	The NERC standard assigns a retention period for the two most recent performances of maintenance activity which implies two intervals of documentation being maintained. The NSRS does not agree that requiring all data for two full cycles is warranted. The volume and length of data retention is unreasonable. The NSRS recommends that the entity retain the last test date with the associated data, plus the prior cycle test date only without retaining the test data.
Response: Thank you for your comments. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one. The SDT has specified the data retention in the posted Standard to establish this level of documentation.		
Pepco Holdings, Inc. - Affiliates	No	The present wording regarding data retention states - The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous on-site audit date, whichever is longer. This wording was changed by the SDT following comments received from Draft 1. However, the present wording is somewhat confusing. It is assumed that the intent of the SDT was to require documentation be retained for the two most recent performances of each distinct maintenance activity, regardless of when they occurred (i.e., whether prior to, or since the last audit), since the phrase whichever is longer was used. In addition, for those activities requiring short maintenance intervals (such as battery inspections), records must be kept for all performances (not just the last two) that have taken place since the last on-site audit. For example: Assume a PSMP with a 6 year interval for relay maintenance and 3 month interval for battery inspections. At a particular station assume the batteries have been inspected every 3 months; the relays were last inspected 5 years ago, and before that 11 years ago. The last audit was 2 years ago. Records from each 3 month battery inspection going back to the last audit needs to be retained. Also, both relay maintenance records from 5 and 11 years ago needs to be retained, despite the fact that this interval should

Organization	Yes or No	Question 3 Comment
		have been reviewed during the last audit. Documentation from the 11 year ago activity can be discarded when the relays are next maintained. Is this what the SDT intended? If so, the requirement should be re-worded to better explain the intent. Also, examples should be included in either the FAQ or Supplemental Reference to demonstrate what is expected.
Response: Thank you for your comments. You understand the data retention correctly as intended by the SDT and specified in the draft standard. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one, as well as data to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted Standard to establish this level of documentation. .		
We Energies	No	The requirement to retain data for the two most recent maintenance cycles is excessive. The required data should be limited to the complete data for the most recent cycle, and only the test date for the previous cycle.
Response: Thank you for your comments. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one. The SDT has specified the data retention in the posted Standard to establish this level of documentation.		
Long Island Power Authority	No	1. Two most recent performances of each distinct maintenance activity for the Protection System components will require data retention for an extended period of time. For example, in certain cases, battery maintenance is on a 12 year cycle which suggests that records need to be retained for 24 years. LIPA suggests retaining data for the most recent maintenance activity. 2. LIPA seeks clarification on “on-site audit” - does it include audits by any of the following - NPCC/NERC/FERC. Also, several small entities do not have on-site audits and participate in off-site audits. Hence, LIPA suggests deleting “on-site” from the requirement. In addition further clarification is required to the Data Retention section to

Organization	Yes or No	Question 3 Comment
		coordinate with the statement in FAQ (Section IV.d p. 22 redline).
Response: Thank you for your comments. **1.** In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one; thus, records for maintenance which is performed every 12 years will need to be retained for 24 years.. The SDT has specified the data retention in the posted Standard to establish this level of documentation. Audits may be by any of the entities listed. The term “on-site” has been replaced by “scheduled” to address your concern.		
Northeast Utilities	No	Two most recent performances of each distinct maintenance activity for the Protection System components will require data retention for an extended period of time. From the FAQ, it is understood that “the intent is not to have three test result providing two time intervals, but rather have two test results proving the last interval”. However two intervals still results in an extended period of time. For example, for a twelve year interval, data would need to be retained for ~24 years. During that period of time a number of on-site audits would have been completed - it is not clear why the requirement is the longer of the two most recent performances or to the previous on site audit date.
Response: Thank you for your comments. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one. The SDT has specified the data retention in the posted Standard to establish this level of documentation.		
MidAmerican Energy Company	No	Verification of compliance with the maximum time intervals for testing only needs to include retention of the documentation of the two most recent maintenance activities. The phrase “or to the previous on-site audit (whichever is longer)” should be deleted.
Response: Thank you for your comments. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one, as well as data to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory		

Organization	Yes or No	Question 3 Comment
compliance). The SDT has specified the data retention in the posted Standard to establish this level of documentation.

Nebraska Public Power District	Yes	Additional guidance on what is acceptable evidence is always good.
Response: Thank you for your comments. In addition to the lists within the Measures, the FAQ (IV.1.B) and Section 15.7 of the Supplementary Reference Document provide additional guidance about acceptable evidence.		
Florida Municipal Power Agency	Yes	M1 could be shortened to just a program in accordance with R1, rather than repeat the entire requirement
Response: Thanks you for your comments. The restatement of the definition has been removed from Measure M1, but the Reliability		

Organization	Yes or No	Question 3 Comment
Standards Development Procedure specifies that Measures contain levels of detail similar to Measure M1 as posted.		
NERC Staff	Yes	Make sure that the use of verbs like “shall,” “should,” and “will” is consistent across Requirements and Measures. In these four measures, all three verbs are used, and they should be made uniform to avoid misinterpretation.
Response: Thank you for your comments. The Measures have been modified to consistently use “shall.”		
Manitoba Hydro	Yes	No issues or concerns at present
Response: Thank you.		
SERC Protection and Control Sub-committee (PCS)	Yes	The SERC PCS expresses no comments on this question.
Response: Thank you.		
FirstEnergy	Yes	We agree with the Measures but suggest some improvements: 1. In Measures M2 and M3, the term "should" must be changed to "shall" 2. In Measure M2, the Distribution Provider entity is missing
Response: Thank you for your comments. 1. Measure M2 and Measure M3 have been modified as suggested. **2.** Distribution Provider has been added to Measure M2.		
Santee Cooper	Yes	We are concerned with the long-term implementation of the data retention requirements for activities with long maximum intervals. For example, if you are performing an activity that is required every 12 years, the implementation plan says that you should be 100% compliant

Organization	Yes or No	Question 3 Comment
		in 12 years following regulatory approval. However, assuming that 100% compliant meant that you got through all of your components once, you still would not be able to show the last two test dates. 12 years from now, would you still have to discuss the program you were using prior to 12 years ago for those components to have a complete audit, because of having to address the last 2 test dates?
Response: Thank you for your comments. First of all, the Data Retention presumes a stable Standard that has been in effect. Further, the SDT believes that Compliance Monitors will assess compliance for activities performed before the effective date of this Standard using the program that you had in place previously. Therefore, the documentation for your program under PRC-005-1 (whatever it may have been) will serve as your "second interval" documentation until supplanted by new PRC-005-2 records.		

4. The SDT has included VSLs with this posting. Do you agree with the assignments that have been made? If not, please provide specific suggestions for change.

Summary Consideration: Many commenters were concerned about the basis for the percentage increments for different severities of VSLs; these commenters were referred to the VSL Guidelines which propose a Lower VSL as noncompliant with "5% or less," the Medium VSL as "more than 5% but less than (or equal to) 10%," the High VSL as "more than 10% up to (and including) 15%," and the Severe VSL as "more than 15% noncompliant.".

Similarly, many commenters suggested that binary VSLs be assigned a Lower or High rather than a Severe, and were also referred to the VSL Guidelines which indicate that total noncompliance with a requirement is a Severe VSL. VSLs are not indicators of "importance" or "reliability-related risk" – VSLs are an indication of the degree of noncompliant performance.

The VSL for Requirement R4 was modified to add stepped VSLs relating to resolution of maintenance-correctable issues in response to several comments.

Several commenters suggested that the Lower VSL for R4 start at 1% rather than 5%, which is not in accordance with the VSL Guidelines.

Organization	Yes or No	Question 4 Comment
PPL Supply		No Comment.
Xcel Energy		No comments
San Diego Gas & Electric	No	
The Detroit Edison	No	

Organization	Yes or No	Question 4 Comment
Company		
GDS Associates	No	1. We do agree with the majority of the assignments that have been made, however the standard needs specific guidance so to be clearly evidentiated the components as included in the definition of Protection System. The applicability of the standard does not address the current issues regarding radial + load serving only situation when Protection System not designed to provide protection for the BES. 2. Not sure if the percentages corresponding to the events and activities are appropriately assigned. What were the criteria on which all these percentages are based upon? 3. Requirement R3 Severe VSL note 3 allows smaller segment population than the Lower VSL. How these segment limits were developed?
Response: Thank you for your comments. 1. This is an issue related to your Regional BES definition, not to the VSLs. 2. The VSL Guidelines, developed in accordance with the FERC VSL Order, establish the Lower VSL for stepped VSLs as “5% or less,” the Medium VSL as “more than 5% but less than (or equal to) 10%,” the High VSL as “more than 10% up to (and including) 15%,” and the Severe VSL as “more than 15%.” **3.** The segment limits for Requirement R3 and Attachment A were developed according to statistical references to assure that performance-based programs are based on a statistically-significant population. See Section 9 of the Supplementary Reference Document. The Lower VSL addresses “a slightly smaller segment population” than specified; the Severe VSL addresses “a significantly smaller segment population” than specified.		
Ameren	No	1) The Lower VSL for all Requirements should begin above 1% of the components. For example for R4: “Entity has failed to complete scheduled program on 1% to 5% of total Protection System components.” PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm

Organization	Yes or No	Question 4 Comment
		reliability in that valuable resources will be distracted from other duties. 2) In R1, a "Failure to specify whether a component is being addressed by time-based, condition-based, or performance-based maintenance" by itself is a documentation issue and not an equipment maintenance issue. Suggest this warrants only a lower VSL, especially when one of the required components can only be time based. It is possible that a component that failed to be individually identified per R1.1 was included by entity A's maintenance plan. This documentation issue gets a higher VSL than entity B that identified a component without maintaining it. We suggest the R1 VSL be change to Low, since we believe lack of maintenance to be more severe than documentation issues.
Response: Thank you for your comments. 1. The SDT shares your concerns regarding the Lower VSL portion of the stepped VSLs not providing any tolerance for non-conformance without being non-compliant. However, the VSL Guidelines, which conform to the FERC VSL Order, specify that Lower shall be "5% or less." **2.** The VSL for Requirement R1 addresses various levels of severity for degrees of non-compliance. The VSL Guidelines, developed in accordance with the FERC VSL Order, establish that if only a single VSL is provided, it must be Severe. The reliability-related risk related to noncompliance with this requirement is addressed by the VRF being assigned as Lower.		
Entergy Services	No	1. R4: A "Failure to specify whether a component is being addressed by time-based, condition-based, or performance-based maintenance" by itself is a documentation issue and not an equipment maintenance issue. Suggest this warrants only a lower VSL, especially when one of the required components can only be time based. 2. R4: Suggest a stepped VSL for "Entity has failed to initiate resolution of maintenance-correctable issues". While we understand the importance of addressing a correctable issue, it seems like there should be some allowance for an isolated unintentional failure to address a correctable issue. If possible, consider the potential impact to the system. For example, a failure to address a pilot scheme correctable issue for an entity that only employs pilot schemes for system stability applications should not necessarily have the

Organization	Yes or No	Question 4 Comment
		same VSL consequence as an entity which employs pilot schemes everywhere on their system as a standard practice.
Response: Thank you for your comments. 1. This actually addresses the VSL for Requirement R1, which addresses various levels of severity for degrees of non-compliance. The risk related to this is addressed by the VRF being assigned as Lower. **2.** The VSL for Requirement R4 has been modified to provide stepped VSLs for initiation of resolution of maintenance-correctable issues.		
WECC	No	Compliance does not agree. The R1 VSL allows too much to interpret. What does no more than 5% of the component actually use to define the percentage; it should be specific if it is referring to the weight of each component and how many components are there. For example, Protective Relay is one component of five. In addition the VSL for Lower, Moderate and High states in the first paragraph that the entity included all of the "Types" of components according to the definition, though failed to "Identify the Component". It needs clarity on how it can be included though not specifically identified like the next two bullets. The same concern applies to R2 and R4. Be specific about what is included (or not) to calculate those percentages.
Response: Thank you for your comments. The percentages will depend to a large degree how the entity describes their components. A definition of "Component" has been added to the Standard to provide guidance and help provide consistency.		
Constellation Power Generation	No	Constellation Power Generation does not agree with the proposed data retention section. Retaining and providing evidence of the two most recent performances of each distinct maintenance activity should be sufficient. For entities that have not been audited since June of 2007, having to retain evidence from that date to the date of an audit could contain numerous cycles, which is cumbersome and does not improve the reliability of the BES.
Response: Thank you for your comments. This comment is not relevant to VSLs. In order for a Compliance Monitor to be assured of		

Organization	Yes or No	Question 4 Comment
compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one, as well as data to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted Standard to establish this level of documentation.		
Northeast Utilities	No	For R1 under Severe VSL - suggest moving the first criteria “The entity’s PSMP failed to address one or more of the type of components included in the definition of “Protection System” under High VSL since this criteria cannot have the same VSL level as “Entity has not established a PSMP”.
Response: Thank you for your comments. The SDT believes that, if an entity has missed one (of the five) entire component types in their program, they do not have a complete program.		
Florida Municipal Power Agency	No	1. For the VSLs of R1 and R2, we do not understand where the 5%, 10% come from. There are only a few types of components, relays, batteries, current transformers and voltage transformers, DC control circuitry, communication, that’s 6 component types by our count, so, missing 1 component type in discussing the type of maintenance program is already a 17% error and Low, Medium and High VSLs are meaningless as currently drafted and every violation would be Severe, was the intention to apply this is a different fashion? 2. Perfection is Not A Realistic Goal R4 allows no mistakes. Even the famous six sigma quality management program allows for defects and failures (i.e., six sigma is six standard deviations, which means that statistically, there are events that fall outside of six standard deviations). PRC-005 has been drafted such that any failure is a violation, e.g., 1 day late on a single relay test of tens of thousands of relays is a violation. That is not in alignment with worldwide accepted quality management practices (and also makes audits very painful because statistical, random sampling should be the mode of audit, not 100% review as is currently being done in many instances). FMPA suggests considering statistically based performance metrics as opposed to an unrealistic performance target that does not allow for any failure ever. Due to the shear volume of

Organization	Yes or No	Question 4 Comment
		relays, with 100% performance required, if the standards remain this way, PRC-005 will likely be in the top ten most violated standards for the forever. In other words, 1-2% of components outside of the program should be allowed without a violation and Low VSL should start at a non-zero number, such as “Entity failed to complete scheduled program for 3-6% of components based on a statistically significant random sampling” or something to that affect. 3. There is a fundamental flaw in thinking about reliability of the BES. We are really not trying to eliminate the risk of a widespread blackout; we are trying to reduce the risk of a widespread blackout. We plan and operate the system to single and credible double contingencies and to finite operating and planning reserves. To eliminate the risk, we would need to plan and operate to an infinite number of contingencies, and have an infinite reserve margin, which is infeasible. Therefore, by definition, there is a finite risk of a widespread blackout that we are trying to reduce, not eliminate, and, by definition, by planning and operating to single and credible double contingencies and finite operating and planning reserves, we are actually defining the level of risk from a statistical basis we are willing to take. With that in mind, it does not make sense to require 100% compliance to avoid a smaller risk (relays) when we are planning to a specified level of risk with more major risk factors (single and credible double contingencies and finite planning and operating reserves).

Response: Thank you for your comments.

1. The VSL Guidelines, developed in accordance with the FERC VSL Order, establish the Lower VSL for stepped VSLs as “5% or less,” the Medium VSL as “more than 5% but less than (or equal to) 10%,” the High VSL as “more than 10% up to (and including) 15%,” and the Severe VSL as “more than 15%.” Much of this comment seems to relate to the VSL for Requirement R1; this VSL has been extensively revised, and additional terms have been added to the Definitions section to clarify.
2. The SDT shares your concerns regarding the Lower VSL portion of the stepped VSLs not providing any tolerance for non-conformance without being non-compliant. However, the VSL Guidelines, which conform to the FERC VSL Order, specify that Lower shall be “5% or less.” The VRF and VSLs are only a starting point in determining the size of a penalty or sanction – the

Organization	Yes or No	Question 4 Comment
Compliance Enforcement Authority has latitude to consider aggravating factors and mitigating factors in determining whether there should be any penalty, and the size of any penalty. These mitigating and aggravating factors are oultined in the Compliance Monitoring and Enforcement Program. http://www.nerc.com/files/Appendix4C_Uniform_CMEP_10022009.pdf **3.** The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation.		
Santee Cooper	No	In R1, a “Failure to specify whether a component is being addressed by time-based, condition-based, or performance-based maintenance” by itself is a documentation issue and not an equipment maintenance issue. Suggest this warrants only a lower VSL, especially when one of the required components can only be time based.
Response: Thank you for your comments. The VSL for Requirement R1 addresses various levels of severity for degrees of non-compliance.		
SERC Protection and Control Sub-committee (PCS)	No	In R1, a “Failure to specify whether a component is being addressed by time-based, condition-based, or performance-based maintenance” by itself is a documentation issue and not an equipment maintenance issue. Suggest this warrants only a lower VSL, especially when one of the required components can only be time based.
Response: Thank you for your comments. The VSL for Requirement R1 addresses various levels of severity for degrees of non-compliance.		
Progress Energy Carolinas	No	In the VSL for R1, a failure to “specify whether a component is being addressed by time-based, condition-based, or performance-based maintenance” by itself is a documentation issue and not an equipment maintenance issue. Suggest this warrants only a lower VSL, especially when one of the required components can only be time based.
Response: Thank you for your comments. The VSL for Requirement R1 addresses various levels of severity for degrees of non-		

Organization	Yes or No	Question 4 Comment
compliance.		
Pacific Northwest Small Public Power Utility Comment Group	No	is possible that a component that failed to be individually identified per R1.1 was included by entity A's maintenance plan. This documentation issue gets a higher VSL than entity B that identified a component without maintaining it. We suggest the R1 VSL be change to Low, since we believe lack of maintenance to be more severe than documentation issues.
Response: Thank you for your comments. The VSL for Requirement R1 addresses various levels of severity for degrees of non-compliance. The risk related to non-compliance with the various requirements is addressed by assignment of the associated VRFs. Additionally, Requirement R1 and the associated VSLs have been substantially modified, and may address your concern.		
Pepco Holdings, Inc. - Affiliates	No	It is possible that a component that failed to be individually identified per R1.1 was included by entity A's maintenance plan. This documentation issue gets a higher VSL than entity B that identified a component without maintaining it. We suggest the R1 VSL be change to Low, since we believe lack of maintenance to be more severe than documentation issues.
Response: Thank you for your comments. The VSL for Requirement R1 addresses various levels of severity for degrees of non-compliance.		
PNGC Power	No	It is possible that a component that failed to be individually identified per R1.1 was included by entity A's maintenance plan. This documentation issue gets a higher VSL than entity B that identified a component without maintaining it. We suggest the R1 VSL be change to Low, since we believe lack of maintenance to be more severe than documentation issues.
Response: Thank you for your comments. The VSL for Requirement R1 addresses various levels of severity for degrees of non-compliance.		
Long Island Power Authority	No	1. R4 under Severe VSL mentions - Entity has failed to initiate resolution of maintenance-correctable issues. What proofs will satisfy the requirement that the entity has initiated the resolution.

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 4 Comment</th></tr>
<tr><td></td><td></td><td>2. R1 under Severe VSL - LIPA suggests moving the first criteria “The entity’s PSMP failed to address one or more of the type of components included in the definition of “Protection System” under High VSL since this criteria cannot have the same VSL level as “Entity has not established a PSMP”.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.
1. The SDT is unable to categorically state what will satisfy a Compliance Monitor, but it seems that a work order addressing the maintenance-correctable issue would be one example. FAQ IV.1.B and Section 15.7 of the Supplementary Reference Document may also be helpful.
2. The SDT believes that if an entity has missed one (of the five) entire component types in their program, they do not have a complete program.</td></tr>

Organization	Yes or No	Question 4 Comment
MidAmerican Energy Company	No	The lower VSL specification for R4 should allow for a small level of incomplete testing. Suggest changing “5% or less” to “from 1% to 5%”.
Response: Thank you for your comments. The SDT shares your concerns regarding the Lower VSL portion of the stepped VSLs not providing any tolerance for non-conformance without being non-compliant. However, the VSL Guidelines, which conform to the FERC VSL Order, specify that Lower shall be “5% or less.”The VRF and VSLs are only a starting point in determining the size of a penalty or sanction – the Compliance Enforcement Authority has latitude to consider aggravating factors and mitigating factors in determining whether there should be any penalty, and the size of any penalty. These mitigating and aggravating factors are oultined in the Compliance Monitoring and Enforcement Program. http://www.nerc.com/files/Appendix4C_Uniform_CMEP_10022009.pdf		
Springfield Utility Board	No	The Violation Risk Factors are problematic. 1. With all due respect, it seems that NERC still operates in a "BIG UTILITY" mind set. Big utilities have potentially hundreds or thousands of components under different device types. Looking at the VRFs, the percentages 5% or 15% as an example, are looked at based on a deep pool of multiple devices so a "BIG UTILITY" that misses a component or small number of components may not trigger a high severity level. However a small utility may have only a handful of components under each type. Therefore if the small utility were to miss one component all of a sudden the utility automatically triggers the 5% or 15% threshold. This type of dynamic unreasonable and not equitable. Therefore (in an attempt to work within the framework proposed), SUB proposes that there be a minimum number of components that might not be in compliance which result in a much lower Violation Severity Level. SUB suggests that NERC try to create a level playing field. If 15% of a Big Utility's total number of components averages at around 15 out of 100 total then perhaps a reasonable outcome would be that up to 5 components (regardless of the total number of components an entity has under each type) could be in violation without tripping into a high VSL.(the 5 components threshold may not apply to all types, this is just for illustrative purposes).

Organization	Yes or No	Question 4 Comment
		2. Also, are the missed components compounding? For example, if an entity missed 5 components on year three and another 5 components in year 10 is the VSL based on 10 components or 5 components. There should be a time horizon attached to the VSL such that the VSL does not count prior components that were brought into compliance through a past action. That intent may be to not have the VSLs be based on compounding numbers of components; however that should be made clear.
Response: Thank you for your comments. You discussed VRFs, but it appears that you are actually discussing VSLs. 1. The SDT shares your concern about the stepped VSLs. However, the VSL Guidelines, developed in accordance with the FERC VSL Order, establish the Lower VSL for stepped VSLs as “5% or less,” the Medium VSL as “more than 5% but less than (or equal to) 10%,” the High VSL as “more than 10% up to (and including) 15%,” and the Severe VSL as “more than 15%.” The SDT did, however, modify the VSLs for R1 so that they do not use percentages. **2.** The VSLs are assigned on the basis of percentages of components for which you are non-compliant. The SDT suggests that you review the Compliance Monitoring Enforcement Program for clarification on self-reports, and so forth.		
Tennessee Valley Authority	No	The Violation Severity Level Table listing for Requirement R4 lists the following under “Severe VSL”.”Entity has failed to initiate resolution of maintenance-correctable issues” The threshold for a Severe Violation in this case is too broad and too subjective. The threshold needs to be clearly defined with low, medium, and high criteria.
Response: Thank you for your comments. The VSLs for Requirement R4 have been modified to provide stepped VSLs for initiation of resolution of maintenance-correctable issues.		
BGE	No	The VSL’s as proposed may be reasonable but it is difficult to endorse them until the ambiguity in R1.1 is reduced.
Response: Thank you.		
Duke Energy	No	The VSLs for PRC-005-2 requirements R1, R2 and R4 have significantly tighter

Organization	Yes or No	Question 4 Comment
		percentages than the corresponding requirements in PRC-005-1. We believe that the Lower VSL should be up to 10%, the Moderate VSL should be 10%-15%, the High VSL should be 15% to 20%, and the Severe VSL should be greater than 20%, which is still a lower percentage than the 25% Lower VSL currently in PRC-005-1.
Response: Thank you for your comments. The SDT shares your concern abuout the stepped VSLs. However, the VSL Guidelines, developed in accordance with the FERC VSL Order, establish the Lower VSL for stepped VSLs as “5% or less,” the Medium VSL as “more than 5% but less than (or equal to) 10%,” the High VSL as “more than 10% up to (and including) 15%,” and the Severe VSL as “more than 15%.”		
Indeck Energy Services	No	1. The VSL's treat all entities, components and problems alike. By combining 4 protection maintenance standards, it elevates the VSL on otherwise minor problems to the highest levels of any of the predecessor standards. The threshold percentages are very arbitrary. Severe VSL doesn't in any way relate to reliability. For a small generator to miss or mis-categorize 1 out of 7 relays is unlikely to have any impact on reliability, much less deserving a severe VSL. The R2 & R4 VSL's don't care about results of the program, only whether all components are covered. Half of the components could fail annually and it’s not a Severe VSL. 2. The R3 VSL allows 4% countable events, which can be hundreds for a large entity and only allows a few for a small entity.
Response: Thank you for your comments. 1. The VSL Guidelines, developed in accordance with the FERC VSL Order, establish the Lower VSL for stepped VSLs as “5% or less,” the Medium VSL as “more than 5% but less than (or equal to) 10%,” the High VSL as “more than 10% up to (and including) 15%,” and the Severe VSL as “more than 15%.” VSLs are not intended to assess the risk to reliability of noncompliance, VSLs are intended to identify different degrees of noncompliance with the associated requirement. The VRFs assess the risk to reliability of noncompliance with the requirement. **2.** Relating to the R3 VSL, the “4% countable events” corresponds to the requirement relevant to performance-based programs in Attachment A. This value was determined to be a statistically significant value relating to performance-based programs, which		

Organization	Yes or No	Question 4 Comment
may not be practical for a small entity to implement without aggregation with other entities having similar programs. See Section 9 of the Supplementary Reference Document.		
US Bureau of Reclamation	No	1. The VSL's use terms that are not tied back to a requirement and appear to be based on the concept that every component will cause an impact on the BES. The VSL's use the term "countable event" to score the VSL; however, there is no requirement associated with the number of "countable events". 2. The VSL's should allow for minor gaps in maintenance documentation where there is no impact to the BES if the component failed.
Response: Thank you. 1. The VSL for Requirement R3, which you are questioning, addresses limits on "countable events" as they relate to the requirements for a Perfomance Based program within Attachment A. 2. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. The VRF and VSLs are only a starting point in determining the size of a penalty or sanction – the Compliance Enforcement Authority has latitude to consider aggravating factors and mitigating factors in determining whether there should be any penalty, and the size of any penalty. These mitigating and aggravating factors are oultined in the Compliance Monitoring and Enforcement Program. http://www.nerc.com/files/Appendix4C_Uniform_CMEP_10022009.pdf		
Black Hills Power	No	-VSL's are based on percentages of components, where the definition of a 'component' is in many cases up to the entity to interpret (see PRC-005-2 FAQ sheet, Page 2). Basing VSL's on an entities interpretation (or count) of 'components' is not an equitable measure of severity level.
Response: Thank you for your comment. A definition of "Component" has been added to the Standard to provide guidance and help provide consistency.		
JEA	No	We could find no rational provided for the % associated with each VSL, or component

Ameren	No	1) Is this document considered part of the standard? We expect to use it as a reference in developing our PSMP, during audits, and for self-certification as an authentic source of information. It is also unclear how this document will be controlled (i.e. Revised and

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 5 Comment</th></tr>
<tr><td></td><td></td><td>Approved, if at all).
2) On page 22 please clarify that only applies to high speed ground switches associated with BES elements.
3) We appreciate the SDT providing this valuable reference.</td></tr>
<tr><td colspan="3">Response:Thank you for your comments.
1. This document provides supporting discussion, but is not part of the Standard. The SDT intends that it be posted as a reference document, accompanying the Standard. As established in SDT Guidelines, the Standard is to be a terse statement of Requirements, etc., and is not to include explanatory information like that included in the Supplementary Reference document. The SDT intends that this document help explain, clarify, and in some cases suggest methods to comply with the Standard. The Standards Committee has a formal process for determining whether to authorize posting a reference document with an approved standard. That process is posted on the Standard Resources web page – here is a link to the procedure: http://www.nerc.com/files/SC_Process_Approve_Supporting_References_Approved_10Mar08.pdf

2. The Standard applies to High-Speed Ground Switches that are used to trip BES elements or that are used to protect BES elements. In response to your comment, the SDT has modifed the Supplementary Reference Section 15.3 as follows: “The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is “…applied on, or designed to provide protection for the BES…” then this device needs to be treated as any other Protection System component. The control circuitry would have to be tested within 12 years and any electromechanically operated device will have to be tested every 6 years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit then the solenoid triggering unit can easily be tested without the actual closing of the ground blade.

3. Thank you.</td></tr>
<tr><td>Xcel Energy</td><td>No</td><td>1. As we commented on in the previous draft of the standard that proposed the Supplementary Reference and FAQ, we are concerned as to what role these documents will play in compliance/auditing. It is also unclear how these documents will be controlled (i.e. Revised and Approved, if at all).
2. Inconsistencies have been identified between proposed standard and the documents</td></tr>
</table>

Organization	Yes or No	Question 5 Comment
		(e.g. page 29 of FAQ example 1).
Response: Thank you for your comments. 1. This document provides supporting discussion, but is not part of the Standard. The SDT intends that it be posted as a Reference Document, accompanying the Standard. As established in SDT Guidelines, the Standard is to be a terse statement of Requirements, etc., and is not to include explanatory information like that included in the Supplementary Reference document. The Supplementary Reference and FAQ have been revised to make them consistent with the new version of PRC-005-2. The Standards Committee has a formal process for determining whether to authorize posting a reference document with an approved standard. That process is posted on the Standard Resources web page – here is a link to the procedure: http://www.nerc.com/files/SC_Process_Approve_Supporting_References_Approved_10Mar08.pdf 2. Thank you. The FAQ has been revised to make it consistent with the new version of PRC-005-2 and the Supplementary Reference document.		
Pepco Holdings, Inc. - Affiliates	No	Figure 1 & 2 Legend (page 29), Row 5, Associated Communications Systems, includes Tele-protection equipment used to convey remote tripping action to a local trip coil or blocking signal to the trip logic (if applicable). This description does not include all the various types of signals communicated for proper operation of various protective schemes (i.e., DUTT, POTT, DCB, Current Differential, Phase Comparison, synchro-phasors, etc.) A more inclusive and generic description might be - Tele-protection equipment used to convey specific information, in the form of analog or digital signals, necessary for the correct operation of protective functions. This is also consistent with the revised definition of Protection System. Conversely, excluded equipment would be - Any communications equipment that is not used to convey information necessary for the correct operation of protective functions.
Response: Thank you for your comment. The Supplementary Reference and FAQ have been revised to make them consistent with the new version of PRC-005-2 and each other, and to incorporate language similar to your suggestion.		

Organization	Yes or No	Question 5 Comment
MEAG Power	No	Further clarification is needed. The information provided on verifying outputs of voltage and current sensing devices is confusing. In one part, it indicates that the intent is to verify that intended voltages and currents are getting to the relay apparently without regards to accuracy. A practical method of verifying the output of VTs and CTs is not identified and need to be identified.
Response: Thank you for your comments. The intent of the maintenance activity is to verify that the necessary values reach the protective relays. The SDT believes that a maintenance plan that requires infra-red scanning of VTs and CTs is not sufficient. The SDT further believes that routine commissioning tests, while certainly allowed, need not be required in the Standard because mere ratio tests would not prove that the values reach the relay. A practical method is to read the values at the relays and, as you state, verify that the quantities meet your needs. The SDT believes that the discussion in Section 15.2 of the Supplementary Reference is sufficient, and is supplemented in several subsections of FAQ II.3.		
Indeck Energy Services	No	In 2.3, the applicability is stated to have been modified. As discussed at the FERC Technical Conference on Standards Development, the goal of the standards program is to avoid or prevent cascading outages--specifically not loss of load. The modified applicability moves away from the purpose of the standards program to an undefined fuzzy concept. Applicable Relays ignore the fact that some relays, or even some entities, have little to no affect on reliability. The global definition of Protective System encompasses all equipment, and doesn't differentiate the components that meet the purpose of the standards program. The Supplementary Reference doesn't overcome the inherent shortcomings of the standard.
Response: Thank you for your comments. The Supplementary Reference is intended to help clarify the Standard.		

Organization	Yes or No	Question 5 Comment
The United Illuminating Company	No	Include a detailed example of an Inventory list. Allow for different means of maintaining the lists electronically, that is, as spreadsheets, or databases.
Response: Thank you for your comments. The Supplementary Reference is intended to help clarify the Standard, not add to the Requirements of the Standard. Maintaining your lists is a business practice that you make, spreadsheets and/or databases have not been precluded in the Standard or in any reference document.		
US Bureau of Reclamation	No	It is not reasonable to assert that a statistical analysis of survey data is reliability based justification for requiring specific maintenance intervals. The reference document admits that intervals varied widely. To assert a postage stamp interval does not account for other variables which optimize a specific maintenance program. That is not saying that the reference documents are worthless. Indeed it has many good suggestions. However, to impugn the maintenance programs in practice because they do not follow the "weighted average" is hardly scientific or credible. The reference document should analyze the maintenance programs from the stand point of the outages associated with those facilities. If a specific maintenance practice was shown to have compromised the performance of the facility and the reliability of the BES, then it would added to the statistical database of practices which would not be acceptable. Now the statistical analysis of the database would show that certain practices have consequences which impact reliability and a requirement can be constructed to disallow them.
Response: Thank you for your comments. FERC directed the SDT to set maximum time intervals between maintenance activities. The SDT recognized that different types of equipment, different generations of equipment, different failure modes of equipment and different versions of time-based maintenance had to be considered. The SDT agrees with the commenter that the Standard allows statistical analysis and performance-based maintenance allows an entity to create time intervals that could exceed any “weighted-averages” time-based intervals. The Supplementary Reference adds a section (9) to show how an entity can create a performance-based maintenance interval.		

Organization	Yes or No	Question 5 Comment
Public Service Enterprise Group ("PSEG Companies")	No	1. Suggest that figure 2 has a line of demarcation added that shows components specifically not part of the standard requirements. (Medium voltage bus). 2. Battery charger should be removed from table of components when a storage battery is used for the DC supply.
Response: Thank you for your comments. 1. The figures are intended to be general information and not to be inclusive of all situations. **2.** The modification of the Protection System definition from "station battery" to "station dc supply" is intended to include battery chargers, and Table 1-4 within draft PRC-005-2 includes activities specifically related to battery chargers.		
JEA	No	The Supplementary Reference document is critical in our current compliance environment to be approved as part of the standard and any standard modifications need to be kept in synchronization with the FAQ and the Supplementary Reference.
Response: Thank you for your comments. **1.** This document provides supporting discussion, but is not part of the Standard. The SDT intends that it be posted as a reference document, accompanying the S. As established in SDT Guidelines, the Standard is to be a terse statement of requirements, etc., and is not to include explanatory information like that included in the FAQ and Supplementary Reference. The Supplementary Reference and FAQ have been revised to make them consistent with the new version of PRC-005-2.		
Long Island Power Authority	No	1. There is no guidance on how to calculate the total number of components and thus, the percentages under different severity levels. FAQ provides some insight into how an entity can count components however; an example in the reference document will provide clarity. 2. Page 7 of the redline version of Supplemental Reference - bullet 1 under Maintenance Services, paragraph 2, it says " If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock

Organization	Yes or No	Question 5 Comment
		is reset for those components. LIPA believes that resetting the time clock will make tracking difficult (unless entities have a sophisticated automated tool for tracking). Another option where an entity can take credit for a correct performance within specifications at the time of the maintenance cycle should be included.
Response: Thank you for your comments. 1. A definition of "Component" has been added to the draft Standard to provide guidance. The Standard and the Tables have also been revised throughout for clarity. **2.** The example cited is only offered as an option for entities that may wish to make use of observed real-time operations within their PSMP. An entity may, if desired, reset the time clock on a correct real-time occurrance. An entity does not have to "reset the time clock" if it chooses to maintain all of its components on a set schedule. The example given is merely one method to log a completed tripping action, which would alleviate the need to validate that same trip path. The SDT acknowledges that there are many ways to prove circuits; real-time switching or fault-clearing activities can be used but are not the only methods.		
Northeast Power Coordinating Council	No	1. There is no guidance on how to calculate the total number of components and thus, the percentages under different severity levels. FAQ provides some insight into how an entity can count components. 2. However; an example in the reference document will provide clarity. Page 7 of the redline version of Supplemental Reference - bullet 1 under Maintenance Services, paragraph 2 states " If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock is reset for those components." Resetting the time clock will make tracking difficult (unless entities have a sophisticated automated tool for tracking). Another option where an entity can take credit for a correct performance within specifications at the time of the maintenance cycle should be included.
Response: Thank you for your comments. 1. A definition of "Component" has been added to the draft Standard to provide guidance. The Standard and the Tables have also		

Organization	Yes or No	Question 5 Comment
been revised throughout for clarity. **2.** The example cited is only offered as an option for entities that may wish to make use of observed real-time operations within their PSMP. An entity may, if desired, reset the time clock on a correct real-time occurrance. An entity does not have to “reset the time clock” if it chooses to maintain all of its components on a set schedule. The example given is merely one method to log a completed tripping action, which would alleviate the need to validate that same trip path. The SDT acknowledges that there are many ways to prove circuits; real-time switching or fault-clearing activities can be used but are not the only methods.		
Northeast Utilities	No	There is no guidance on how to calculate the total number of components and thus, the percentages under different severity levels. FAQ provides some insight into how an entity can count components however; an example in the reference document will provide clarity.
Response: Thank you for your comments. A definition of “Component” has been added to the draft Standard to provide guidance. The Standard and the Tables have also been revised throughout for clarity.		
Tennessee Valley Authority	No	1. There needs to be a defined method of deferral when equipment can’t be gotten out of service until a scheduled outage. 2. Give some examples of what “inputs and outputs that are essential to proper functioning of the Protection System” are. 3. a) Define what a “Control and Trip Circuit” is. 4. b) Is there one per relay? 5. c) Do I have to have a list of them in my work management system?
Response: Thank you for your comments. 1. “Grace periods” within the Standard are not measurable, and could lead to persistently increasing intervals. 2. Some examples of outputs may include but are not limited to: trip, initiate zone timer, initiate breaker fail. Some examples of input may include but are not limited to: breaker fail initiate, start timer. This cannot be an all-inclusive list as any given scheme could have many variations. In short, if your scheme requires a specific input to function properly then you must have that input		

Organization	Yes or No	Question 5 Comment
maintained; if your scheme has a specific output that must function then it must be maintained. If the input or output is used for a non-protective function (such as, but not limited to, Sequence-of-Events Recorder, alarm or indication) then it does not have to be maintained under this Standard. See Section 15.3 of the Supplementary Reference and FAQ II.2.L. 3. a) Circuitry needed for the correct operation of the protective relay. A definition of “Component” has been added to the draft Standard to provide guidance. See Section Section 15.3 of the Supplementary Reference. 4. b) This depends on your scheme and your relay. A definition of “Component” has been added to the draft Standard to provide guidance. **5.** c) The SDT believes that a PSMP that requires maintenance upon all of the circuits, and includes a check-off (list) system that accounts for all circuits being verified would suffice.

WECC	Yes	Compliance does agree with the clarity and the Supplementary Reference should be specially referenced where appropriate the Tables 1a, 1b, 1c and Attachment A that are included with the Standard. But this reference is not a part of the approved standard and there are no controls which prevent changes in the reference document that could impact the scope or intent of the standard. If the standard is approved with reference to the Supplementary Reference then future changes to the Supplementary Reference should not be allowed without due process. Only the version in existence at the time of approval of the

Organization	Yes or No	Question 5 Comment
		standard could be used to clarify or explain the standard.
Response: Thank you for your comments. The SDT intends that the Supplementary Reference document be updated as the Standard is revised to maintain its relevance to the application of the Standard. The Standards Committee has a formal process for determining whether to authorize posting a reference document with an approved standard. That process is posted on the Standard Resources web page – here is a link to the procedure: http://www.nerc.com/files/SC_Process_Approve_Supporting_References_Approved_10Mar08.pdf		
Nebraska Public Power District	Yes	Is this document considered part of the standard and may be referenced during audit and self-certification as an authentic source of information?
Response: Thank you for your comments. This document provides supporting discussion, but is not part of the Standard. The SDT intends that these be posted as reference documents, accompanying the Standard. The Standards Committee has a formal process for determining whether to authorize posting a reference document with an approved standard. That process is posted on the Standard Resources web page – here is a link to the procedure: http://www.nerc.com/files/SC_Process_Approve_Supporting_References_Approved_10Mar08.pdf		
Springfield Utility Board	Yes	SUB appreciates that Time Based, Performance Based, and Condition Based programs can be combined into one program. However it should be clear that a utility may include one, two or all three of these types of programs for each individual device type. Currently the language reads:"TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System." The "and" requires all three to be combined if they are combined. SUB suggests the “and” be changed to "or". Language Change: "TBM, PBM, or CBM can be combined for individual components, or within a complete Protection System."
Response: Thank you for your comments. The SDT modified Requirement R1 of the Standard.		
FirstEnergy	Yes	We support the reference document and appreciate the SDT's hard work developing this

Organization	Yes or No	Question 5 Comment
		document. We offer the following suggestions for possible improvements: 1. The reference document should be linked in Section F of the standard. Otherwise it may be difficult for someone to navigate the NERC website in search of the document. 2. Section 2.2 - It would be helpful if a short discussion of the reasons for the changes to the definition of Protection System was included in this reference document. In addition, it would be beneficial to discuss what is included in "dc supply" components, such as "dc supplies include battery chargers which are required to be maintained per the Tables in PRC-005-2." 3. Section 8.1 - The fourth bullet which reads "If your PSMP (plan) requires more then you must document more." Should be removed. This is already covered in the sixth bullet which states "If your PSMP (plan) requires activities more often than the Tables maximum then you must document those activities more often."

Response: Thank you for your comments.

1. This issue may be a good idea. The Standards Committee has a formal process for determining whether to authorize posting a reference document with an approved standard. That process is posted on the Standard Resources web page – here is a link to the procedure: http://www.nerc.com/files/SC_Process_Approve_Supporting_References_Approved_10Mar08.pdf.
2. The reasons for the definition change are transitory and should not be in the Supplementary Reference document. The reasons may be found in the SAR for Project 2007-17. See Section 15.4 of the Supplementary Reference for discussion about batteries and dc supply.
3. The SDT disagrees with your assertion. The first cited example applies to the activities within your program, and the second applies to the intervals. These are related but separate. The fourth bullet in Section 8.1 has been revised to clarify**.**

6. The SDT has revised the "Frequently-Asked Questions" (FAQ) document which is supplied to address anticipated questions relative to the standard. Do you agree with these changes? If not, please provide specific suggestions for change.

Summary Consideration: Most commenters seemed to appreciate the information provided within the FAQ document. Many commenters asked whether the FAQ was part of the Standard, to which the SDT replied, "No." Several commenters also were concerned that the FAQ document may not be kept current with the Standard itself. There were assorted individual technical comments about the FAQ, to which the SDT responded. Several comments irrelevant to the FAQ were also offered; the SDT offered responses relevant to the comments.

Organization	Yes or No	Question 6 Comment
MEAG Power		No comment.
PPL Supply		No Comment.

SERC Protection and Control Sub-committee (PCS)		The SERC PCS expresses no opinion on this question.
Indeck Energy Services	No	
San Diego Gas & Electric	No	
Consumers Energy	No	1. FAQ II.3A attempts to clarify the requirements of "Verify the proper functioning of the current and voltage signals necessary for Protection System operation from the voltage

Organization	Yes or No	Question 6 Comment
Company		and current sensing devices to the protective relays" suggesting that "simplicity can be achieved" by verifying that the protective relays are receiving "expected values." It concludes with a statement of the need to "ensure that all of the individual components are functioning properly ..." implying that just verifying "expected values" at the protective relay end of the circuit may be inadequate. 2. FAQ II.4D describes what is required for testing of aux relays to include, "that their trip output(s) perform as expected". Does that include timing tests? (Example - high speed ABB AR relays vs. standard AR relays). 3. The SDT responses to the Draft 1 comments regarding "grace periods" essentially says, "Absolutely not". However, FAQ IV.1.D reflects data retention requirements relative to an entities' program which includes a grace period!

Response: Thank you for your comments.

1. "Expected values" was intended to convey that the current and/or voltage sensing devices were functioning properly. The SDT intentionally left out any Requirement in the Standard that the values being read at the protective relays be within a specific tolerance because each entity may have valid rationale for tolerances at any level. To find a current or voltage value that is wrong would indicate that something in the voltage or current secondary delivery system is not functioning properly and needs corrective action. Typically an entity can review values measured at the relay and determine that the values are as expected and that the maintenance activity has been satisfied.
2. If an entity has designed a protection scheme which contains parts that need to function in a specific manner then those parts need to be routinely maintained to assure that they perform at that level. The SDT believes that Protection Systems exist at all levels of complexity and that some systems will be easier to test than others, but that all components that are necessary for the proper functioning of the Protection System must be maintained. In short, if an entity decided that specific parts were necessary for the proper operation of the Protection System then those parts need to be routinely maintained.
3. There is no "grace period" allowed by the Standard; a "grace period" is not measurable. That means that the intervals between the specified maintenance activities in the Standard cannot exceed those established within the Tables. However, many entities have built in "allowable extensions" to their intervals (thus creating "grace periods" within their own PSMP). In these particular PSMP's the total time allowed between the specified maintenance activities (including any allowable extensions or "grace periods") does not

Organization	Yes or No	Question 6 Comment
exceed the maximum allowed time interval established in the Standard. For example, an entity has in their PSMP that "…the electro-mechanical relays will be tested every 3 calendar years with a maximum allowable extension of 18 additional calendar months to allow for scheduling difficulties and unplanned emergencies." In this way the entity will be audited to their PSMP, they have added 50% time in the form of their own grace period and the maximum time between the specified maintenance activities does not exceed the time interval established in the Standard. Also see FAQ IV.2.H for additional discussion on this.		
Xcel Energy	No	1. As we commented on in the previous draft of the standard that proposed the Supplementary Reference and FAQ, we are concerned as to what role these documents will play in compliance/auditing. It is also unclear how these documents will be controlled (i.e. Revised and approved, if at all). 2. Inconsistencies have been identified between proposed standard and the documents (e.g. page 29 of FAQ example 1).
Response: Thank you for your comments. **1.** This document provides supporting discussion, but is not part of the Standard. The SDT intends that it be posted as a reference document, accompanying the Standard. As established in SDT Guidelines, the Standard is to be a terse statement of requirements, etc., and is not to include explanatory information like that included in the Supplementary Reference document. The FAQ and the Supplementary Reference documents have been revised to make them consistent with the new version of PRC-005-2. 1. The Standards Committee has a formal process for determining whether to authorize posting a reference document with an approved standard. That process is posted on the Standard Resources web page – here is a link to the procedure: http://www.nerc.com/files/SC_Process_Approve_Supporting_References_Approved_10Mar08.pdf **2.** Thank you. The FAQ has been revised to be consistent with the new version of the Standard.		
Nebraska Public Power District	No	1. FAQ 2.G, page 24 - NPPD believes system reliability will be decreased if an entity is considered non-compliant for exceeding a PSMP stated interval that is within the PRC-005-2 Maximum Maintenance Interval. Considering an entity non-compliant for such a situation will encourage establishment of intervals that only meet the minimum standard. There should be one standard interval that all entities must be monitored against. If an entity wants to perform maintenance more frequently, it should not be subject to non-

Organization	Yes or No	Question 6 Comment
		compliance if it misses its target but meets the Maximum Maintenance Interval in the standard. 2. There are definitions at the beginning of the FAQ that should be contained in the NERC definitions and not in an FAQ. Placing these in an approved definition will help avoid interpretation issues that would arise during future audits.
Response: Thank you for your comments. 1. The SDT believes that there are many reasons that would prompt an entity to have some intervals that are more frequent than those intervals established in the Standard (performance-based maintenance is but a single example). If an entity chooses to perform maintenance more often than the limits set within the Standard then it may do so. If an entity chooses to perform maintenance more often than the limits set within its own PSMP then it may do so. **2.** The SDT desires to conform to certain rules regarding this issue. If a term appears in the NERC Glossary then all Standards will have to conform to the definition established. If the terms are shown elsewhere, in the FAQ for example, then clarity can be achieved when the Standard is read. The SDT intends to help clarify by creating the two supporting reference documents, but not to restrict other Standards to the uses of some words that will inevitably be shared amongst Standards. The SDT has also moved several of these definitions to the Standard with the intent that they be part of only this Standard and not a general definition within the NERC Glossary of Terms.		
Progress Energy Carolinas	No	1. FAQ II.2.A: What degree of testing is required for a relay firmware upgrade? Complete commissioning tests? 2. FAQ V.1.A. There appears to be a typo in Example #1 for “Vented lead-acid battery with low voltage alarm connected to SCADA (level 2)”: Table 1b does not list any level 2 requirements. Rather, the table refers reader back to the Level 1 requirements. Same comment for Example #2 as well. 3. FAQ III.1.A: Project 2009-17 provides a response to a request for interpretation of the term “transmission Protection System” as related to PRC-004-1 and PRC-005-1. The interpretation addresses the boundaries of the transmission system. NERC should

Organization	Yes or No	Question 6 Comment
		investigate whether this same boundary should be defined within the new PRC-005-2. 4. Also, numerous potential boundary issues exist between entities which should be contemplated and addressed. See the examples below: a) Utility A may own equipment in Utility B's substation. Utility A contracts Utility B to perform maintenance on their equipment. However, the two utilities have different maintenance programs and intervals for the same types of equipment. Who is responsible for NERC compliance? Would Utility A be found in violation because their equipment is being maintained under Utility B's program which deviates from Utility A's maintenance basis? b) EMC protection is fed from a utility's instrument transformers. Who is responsible for validation of the relay inputs and testing of the instrument transformers? c) Utility-owned communication units (used for transfer trip or carrier blocking) are coupled to the utility's power line using customer-owned CCVTs. Who is responsible for maintenance and testing of these CCVTs? d) Utility A owns all equipment at one end of line (line terminal A) and Utility B owns all equipment at other end of line (line terminal B). Who is responsible for demonstrating the carrier blocking scheme or POTT scheme works correctly?

Response: Thank you for your comments.

1. Complete commissioning tests can be required by the entity. Commissioning tests are not specified within the Standard. The status of the relay should be that it is ready for use after the firmware upgrade. If the maintenance activities were performed that are specified within the Standard and its PSMP, then the entity may choose to reset the time clock for maintenance for that device.
2. The Tables within the Standard have been completely revised, and the FAQ revised to align.
3. When the interpretation (Project 2009-17) is approved, the SDT for PRC-005-2 will consider if the interpretation is appropriate for PRC-005-2 and make associated changes.

   a) The owner of the equipment is responsible for assuring that the equipment is maintained according to its PSMP. This is

Organization	Yes or No	Question 6 Comment
consistent with the concepts in the Functional Model. b) The owner of the equipment is responsible for assuring that the equipment is maintained according to its PSMP. c) The owner of the equipment is responsible for assuring that the equipment is maintained according to its PSMP. d) The owner of the equipment is responsible for assuring that the equipment is maintained according to its PSMP. The entities should coordinate on equipment that affects each other to assure that the equipment is tested in such a fashion that it complies with both entities' PSMP.		
Tennessee Valley Authority	No	If a relay is tested during a generator outage, what date is allowed to be used for compliance - actual test date or date equipment was returned to service? These are usually only a few weeks apart, but may be as much as three months different.
Response: Thank you for your comments. An entity's own records are used to judge compliance. The date placed on the evidence should be the date on which testing of the relevant Protection System component is completed.		
Northeast Utilities	No	Page 2 under Component definition, term "somewhat arbitrary" is used by the drafting team to address what constitutes a dc control circuit. Though the drafting team has provided entities with flexibility to define as per their methodologies, it is recommended to clearly determine "what constitutes a dc control circuit" since it will be used to determine compliance.
Response: Thank you for your comments. The SDT believes that if the circuit is needed for the Protection System to operate or function correctly, then that circuit must be maintained.		
South Carolina Electric and Gas	No	Question/Answer 4-C (Pg. 10 of FAQ) seems to indicate that by documenting breaker operations for fault conditions the table 1b requirements for control circuitry (Trip Coils and Auxiliary relays) can be satisfied. It is possible that even though a breaker successfully

Organization	Yes or No	Question 6 Comment
		operates for a fault condition one trip coil of a primary/backup design can be inoperable and “masked” by the good trip coil. Although it is likely that a faulty trip coil would be caught by monitoring of continuity it is not a certainty that both trip coils actually operated to clear a fault (example-mechanical binding)
Response: Thank you for your comments. The SDT agrees. While a successful trip operation can fulfill requirements of the Standard, it is useful only for the trip paths for which successful operation was demonstrated and documented.		
BGE	No	The FAQ is a very helpful document. A few more changes would be beneficial. See comments regarding manufactures’ advisories and R1.1 under section 7 below. It is our recommendation that manufacturers service advisories not be an implied part of the PMSP requirements and that the expectations for R1.1 be more explicitly described in the FAQ.
Response: Thank you for your comments. The Supplementary Reference and the FAQ are not a part of the Standard. The intent of the SDT is that the documents help provide clarity, not to imply additional maintenance. The required minimum maintenance activities are listed in the Standard. Requirement R1 and the tables have been extensively revised.		
American Transmission Company	No	The FAQs are helpful, however, with the revised standard as written; ATC has issues with the answers provided. Please refer to Question #7 for areas of concern.
Response: Thank you for your comments. The Standard and the Tables have been revised to add clarity. The FAQ and the Supplementary Reference documents have been revised to make them consistent with the new version of PRC-005-2. Please see our responses to your comments in Question 7.		
MRO’s NERC Standards Review Subcommittee	No	The FAQs are helpful, however, with the revised standard as written, The NSRS has issues with the answers provided. Please refer to Question #7 for areas of concern.

Organization	Yes or No	Question 6 Comment
(NSRS)		
Response: Thank you for your comments. The Standard and the tables have been revised to improve clarity. The FAQ and the Supplementary Reference documents have been revised to make them consistent with the new version of PRC-005-2. Please see our responses to your comments in Question 7.		
Constellation Power Generation	No	The PT/CT testing section is implying that the testing must be completed while energized, which is counter to industry practice at generation facilities. Leeway should be given to the entities to devise their own methods for testing voltage and current sensing devices and wiring to the protection system.
Response: Thank you for your comments. The required minimum maintenance activities are listed in the Standard. The intent of the cited section is to provide examples of how an entity <u>might</u> perform the testing. Any examples listed in either of the supporting documents should be looked upon as suggestions; these suggestions are not considered to be a complete list of the methods available. To the contrary, the Standard and the supporting documents were written considering that there are many ways to achieve a good test. Leeway is certainly available in how an entity complies with the Standard as the maintenance activities generally specify "what" must be achieved but not "how" an entity achieves it. Please see FAQ II.3.D.		
Pepco Holdings, Inc. - Affiliates	No	1. The three month inspection interval for communication equipment mentioned in FAQ II 6 B should be extended to 12 - 18 months (see response to Question #1). 2. In addition, the example used in this section should address what is expected for ON-OFF carrier systems. Checking that the equipment is free from alarms and still powered up does not seem sufficient to verify functionality. The FAQ states that the concept should be that the entity verifies that the communication equipment...is operable through a cursory inspection and site visit. However, unlike FSK schemes where channel integrity can easily be verified by the presence of a guard signal, ON-OFF carrier schemes would require a check-back or loop-back test be initiated to verify channel integrity. If the carrier set was not equipped with this feature, verification would

Organization	Yes or No	Question 6 Comment
		require personnel to be dispatched to each terminal to perform these manual checks.
Response: Thank you for your comments. 1. The SDT believes that the 3-month interval is proper for unmonitored communications systems. **2.** As you suggest, this funcitionality would normally be verified by a manual or automatic checkback system, and, even then, a station visit would be necessary if alarms are not provided. Where such equipment is not available, a station visit would be necessary.		
Public Service Enterprise Group ("PSEG Companies")	No	This is a very useful document and provides a good source of additional information; there are some cases where it could be interpreted as a standard requirement that can lead to confusion if conflicts exist. For example, the group by monitoring level example V.1.A shown on page 29 describes a level 2 partial monitoring as circuits alerting a 24Hr staffed operations center, page 38 shows level 2 monitoring as detected issues are reported daily. The actual standard table 1b level 2 monitor describes alarms are automatically provided daily to a location where action can be taken for alarmed failures within 1 day or less. This is listed as a supplemental reference document in the standard. The FAQ document “supports” the standard but is or is not an official interpretation tool, or if it is state as such.
Response: Thank you for your comments. The FAQ provides supporting discussion, but is not part of the Standard. The SDT intends that it be posted as a reference document, accompanying the Standard. As established in SDT Guidelines, the Standard is to be a terse statement of requirements, etc., and is not to include explanatory information like that included in the FAQ.		
The United Illuminating Company	No	What actions are taken if the owner can not perform a specific activity elaborated on the tables due to the design of the equipment? Is the owner in non-compliance? Must the owner only accept equipment solutions that allow the maintenance activities elaborated in the standard to be performed?

Organization	Yes or No	Question 6 Comment
Response: Thank you for your comments. The SDT is not aware of any activities that cannot be performed as you cite.		
JEA	No	Yes the FAQ is also a very important document to be approved along with the standard. There must be a way to have the standard and the FAQ go hand-in-hand or the standard must be revised to include much of the FAQ.
Response: Thank you for your comments. The FAQ provides supporting discussion, but is not part of the Standard. The SDT intends that it be posted as a reference document, accompanying the Standard. As established in SDT Guidelines, the Standard is to be a terse statement of requirements, etc., and is not to include explanatory information like that included in the Supplementary Reference and the FAQ. The FAQ and the Supplementary Reference documents have been revised to make them consistent with the new version of PRC-005-2. The Standards Committee has a formal process for determining whether to authorize posting a reference document with an approved standard. That process is posted on the Standard Resources web page – here is a link to the procedure: http://www.nerc.com/files/SC_Process_Approve_Supporting_References_Approved_10Mar08.pdf

We Energies	Yes	
Y-W Electric Association, Inc.	Yes	
Ameren	Yes	1) Is this document considered part of the standard? We expect to use it as a reference in developing our PSMP, during audits, and for self-certification as an authentic source of information. It is also unclear how this document will be controlled (i.e. Revised and Approved, if at all). 2) The FAQ needs to be aligned with the tables. The FAQ also contains a duplicate decision tree chart for DC Supply. The FAQ contains a note on the Decision tree that reads, "Note: Physical inspection of the battery is required regardless of level of monitoring used", this statement should be placed on the table itself, and should include the word quarterly to define the inspection period. 3) We appreciate the SDT providing this valuable reference.
Response: Response: Thank you for your comments. 1. The FAQ provides supporting discussion, but is not part of the Standard. The SDT intends that it be posted as a reference document,		

Organization	Yes or No	Question 6 Comment
accompanying the Standard. As established in SDT Guidelines, the Standard is to be a terse statement of requirements, etc., and is not to include explanatory information like that included in the Supplementary Reference and the FAQ. The FAQ and the Supplementary Reference documents have been revised to make them consistent with the new version of PRC-005-2. The Standards Committee has a formal process for determining whether to authorize posting a reference document with an approved standard. That process is posted on the Standard Resources web page – here is a link to the procedure: http://www.nerc.com/files/SC_Process_Approve_Supporting_References_Approved_10Mar08.pdf 2. The FAQ has been revised to make it consistent with the new version of PRC-005-2. The decision trees were removed. 3. Thank you.		
Western Area Power Administration	Yes	Clarification 1) FAQ, page 36, Control Circuit Monitor Level Decision Tree: It's not clear if the note on Level 1 device operation is required for Level 3 monitoring.
Response: Thank you for your comments. The Standard and Tables have been extensively revised. The FAQ has been revised to make it consistent with the new version of PRC-005-2. The decision trees were removed from the FAQ.		
WECC	Yes	Compliance does agree with the clarity. The FAQ answers should be referenced specifically to the Standard and the Supplementary Reference to further understand those two documents. However, endorsement of the Standard should not imply endorsement of the FAQ and vice versa.
Response: Thank you for your comments.		
FirstEnergy	Yes	We support the FAQ document and appreciate the SDT's hard work developing this document. The reference document should be linked in Section F of the standard. Otherwise it may be difficult for someone to navigate the NERC website in search of the document.
4. **Response:** Thank you for your comments. The Standards Committee has a formal process for determining whether to authorize		

Organization	Yes or No	Question 6 Comment
posting a reference document with an approved standard. That process is posted on the Standard Resources web page – here is a link to the procedure: http://www.nerc.com/files/SC_Process_Approve_Supporting_References_Approved_10Mar08.pdf If approved as a permanent reference to a standard, then on the "Reliability Standard" web page, there will be a link (in the same cell as the link to the standard and its archive) to any reference documents approved for posting with the standard.		

7. If you have any other comments on this Standard that you have not already provided in response to the prior questions, please provide them here.

Summary Consideration: Comments were offered on virtually every aspect of the draft Standard. Many of these comments resulted in changes to the Standard. The Tables were commented on heavily, and they were completely revised in response. Many commenters were concerned about not having provision for a "grace period," and the SDT responded that this was not allowable. "100% compliance" was also a concern, and the SDT responded that there was not a means of permitting some level of non-conformance without being also non-compliant.

Organization	Question 7 Comment
GDS Associates	Definition of Terms Used in the Standard. Protection System Maintenance Program 1. Monitoring. Concerned about the interpretation of this activity description 2. Upkeep. Not sure about how this activity will be enforced – A. Introduction. 4.2. Facilities. 3. The applicability does not address the current issues regarding radial + load serving only situation when Protection System not designed to provide protection for the BES. Standard should clearly state this exemption. B. Requirements. 4. 1.1. The standard does not provide guidance in how to identify the components of a transmission Protection System (tPS). See prior comment referring to the case of a radial load serving transmission topology. 5. 1.3. Requirement should read "For each identified Protection System component from Requirement 1, part 1.1, include all maintenance activities listed in PSMP and specified in Tables 1a, 1b, or 1c associated with the maintenance method used per

Organization	Question 7 Comment
	Requirement 1, part 1.2." 6. 1.4. This requirement should be eliminated since already included in Table 1a and covered through Requirement 1, part 1.3. 7. 4.3. Footnote 3 shall be eliminated since duplicates footnote 2 – C. Measures 8. M1. The added wording in the Protection System definition, requirements and measures with respect to the inclusion of the "associated circuitry from the voltage and current sensing devices" and control circuitry "through the trip coil(s) of the circuit breakers or other interrupting devices" seem right but a bit excessive under current circumstances (form of the standard). The standard should clearly specify how the maintenance program will address the verification, monitoring, etc. of the actual wiring and the trip coils. We suggest that the wording of the standard to reflect that the maintenance activities on the wiring will be conducted in a visual fashion without implying activities that require disconnecting the primary equipment. 9. We recommend to change the Protection System definition to read "up to the trip coils(s)" instead the word "through" (see comment on the definition as well). We consider that the gain in reliability by pursuing a thorough maintenance program that require to take primary equipment out of service (which in many instances will lead to the entire substation being put out of service) cannot counterweight the sole purpose of the standard and the economics emerging from this program.

Response: Thank you for your comments.

1. The SDT is unable to determine the nature of your concern. "Monitoring" is used within PRC-005-2 only as discussed in the new Table 2.
2. The SDT has removed "Upkeep" from the PSMP definition in response to your comment.
3. This is an issue for your regional BES definition.

Organization	Question 7 Comment
4. The SDT has extensively revised Requirement R1 and its sub-requirements. 5. The SDT has extensively revised Requirement R1 and its sub-requirements. 6. The SDT has removed Requirement R1, part 1.4, in consideration of your comment. 7. The footnotes have been removed. 8. The SDT is not specifying the means of achieving requirements. This allows entities the flexibility to determine their own optimal methods. 9. The SDT considers that the electrical trip coils are an integral portion of the dc control circuit, and therefore must be exercised.	
Western Area Power Administration	1) Standard, Page 4, R 4.3: Is the utility free to define its own "acceptable limits"? 2) Standard, Page 4, R 4.3: Must the "acceptable limits" be stated in the PSMP? 3) Standard, Page 4, Footnotes 2 and 3 are the same. 4) Attachment A says we can go to a performance based program; does this apply to every part of the standard? In other words, does this apply to component testing, functional testing, etc., and do we define the intervals of the test. That is, do we determine how long we test the sample of at least 30 units that Attachment A discusses?
Response: Thank you for your comments. 1. As "acceptable limits" may vary with the specific application, the entity is expected to determine appropriate acceptable limits. 2. There is no requirement within the draft Standard for an entity to specify the acceptable limits within its own PSMP. 3. The footnotes have been removed. 4. The draft Standard allows entities to implement a performance-based program for all component types except batteries if they have appropriate populations. Attachment A specifies that the entity "Maintain the components in each segment according to the time-based maximum allowable intervals established in Tables 1-1through 1-5 until results of maintenance activities for the segment are available for a minimum of 30 individual components of the segment." After that period, the entity may shift to the performance-based program for the entire segment.	

Organization	Question 7 Comment
Ameren	1) We commend the SDT for developing a generally clear and well documented second draft. The SDT considered and adopted many industry comments from the first draft. It generally provides a well reasoned and balanced view of Protection System Maintenance, and good justification for its maximum intervals. Ameren generally agrees that this second draft will be beneficial to BES reliability, but several inconsistencies, unclear items, and a couple issues need to be addressed before we will be able to support it. 2) Facilities Section 4.2.1 “or designed to provide protection for the BES” needs to be clarified so that it incorporates the latest Project 2009-17 interpretation. The industry has deliberated and reached a conclusion that provides a meaningful and appropriate border for the transmission Protection System; this needs to be acknowledged in PRC-005-2 and carried forward. 3) We are concerned over R1.1, where all components must be identified, without a definition for the word component or the granularity specified. While the FAQ gives a definition, and allows for entity latitude in determining the granularity, the FAQ is not part of the standard. Certainly this could confuse an entity or an auditor and lead to much wasted work and / or violations for unintended or insignificant issues. We suggest that the FAQ definitions be included within the standard. 4) Implementation of the PSMP must coincide with the beginning of a calendar year. 5) Generating Plant system-connected Station Service transformers should not be included as a Facility because they are serving load. Omit 4.2.5.5 from the standard. There is no difference between a station service transformer and a transformer serving load on the distribution system. This has no impact on the BES, which is defined as the system greater than 100 kV. 6) The term “maintenance correctable issue” used in Requirement 4 seems to be at odds with the definition given for it. It seems that an issue that cannot be resolved by repair or calibration during the maintenance activity would be a maintenance non-correctable issue. Also, in Requirement 4, the term “identification of the resolution” is ambiguous. Suggested changes for Requirements 4 and 4.1 are: “R4. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement its PSMP, and resolve any performance problems as follows: 4.3 Ensure either that the components are within acceptable parameters at the conclusion of the maintenance activities or initiate actions to replace the component or restore its performance to within acceptable parameters.”

Organization	Question 7 Comment
Response: Thank you for your comments. 1. Thank you. 2. When the interpretation (Project 2009-17) is approved, the SDT for PRC-005-2 will consider if the interpretation is appropriate for PRC-005-2 and make associated changes. 3. Requirement R1 has been extensively revised, and the SDT has added a definition of "Component" and "Component Type" to the draft Standard. The SDT's intent is that this definition will be used only in PRC-005-2, and thus will remain with the Standard when approved, rather than being relocated to the Glossary of Terms. 4. The SDT Guidelines, which were endorsed by the NERC Standards Committee in April 2009, establishes that proposed effective dates "must be the first day of the first calendar quarter after entities are expected to be compliant." The Implementation Plan is in accordance with these guidelines. 5. The "load" being served by the station service transformer may be essential to operation of the generating plant, and therefore is not the same as general distribution system load. Therefore, the SDT believes that these system components must remain within the Applicability section of the Standard. 6. The definition of "maintenance correctable issue" is consistent with the way it is used within the Standard.	
PPL Supply	1. For applicability to generators, the responsibility for a maintenance program will usually rest with the plant operator when the operator and plant owner(s) are different entities. Consider changing the applicability as it applies to the generator in such situations. 2. Time-based frequency should allow for flexibility; i.e. engineering analysis should allow the entity to exceed the intervals noted in the table. An engineering evaluation that defines a test interval differently than those intervals prescribed in the table should allow an entity to build a program with different intervals. 3. A Grace Period should be defined. This allows a tolerance window to allow for unforeseen occurrences. A grace period would allow for some schedule flexibility and reduce the number of reports to the regulator for exceeding an interval by a reasonable about. 4. The implementation plan for this revision should take into account that a generator outage may be

Organization	Question 7 Comment
	required to implement a new maintenance frequency. The implementation plan should account for outage time, especially nuclear plants that have extended operating cycles. 5. Table 1b Protective Relays Level 2 Monitoring Attributes includes input voltage or current waveform sampling three or more times per power cycle. No further guidance is provided in the reference documents. If this sampling rate is not provided in the specification by the manufacturer, what can the entity use to demonstrate that the attribute is satisfied? Please provide additional guidance. 6. Consider numbering the tables to improve cross-referencing the entries in program documentation. This will allow entities to reference in program documents exactly which activities are being implemented in accordance with the standard. 7. Requirement 1.1 states, "Identify all Protection System components." This is too broad and must be clarified.

Response: Thank you for your concern.

1. The Generator Owner, as defined within V5 of the NERC Functional Model, includes, "Design and authorize maintenance of generation plant protective relaying systems…" No maintenance activities are assigned to the Generation Operator within the Functional Model.
2. Requirement R3 and Attachment A provide the framework and requirements to develop and implement a performance-based maintenance program as you suggest.
3. "Grace periods" within the Standard are not measurable, and would probably lead to persistently increasing intervals. However, an entity may establish an internal program with grace-period allowance, as long as the entire program (including grace periods) does not exceed the intervals within the Standard.
4. The Implementation Plan has been revised in consideration of your comment.
5. This attribute is only relevant to microprocessor-based relays; no other technology possesses this attribute. The entity should contact the manufacturer to obtain this information.
6. The Tables have been completely revised in consideration of your comment.
7. Requirement 1, part 1.1 has been modified to state, "Address all Protection System component types."

Organization	Question 7 Comment
Consumers Energy Company	In the Standard, Footnote 2 and Footnote 3 are identical. We presume that some information has been omitted. We do not agree that Footnotes are an appropriate method of providing information that is important to the application of the Standard. Important information should be provided within the standard text.
Response: Thank you for your comments. The footnotes have been removed.	
Nebraska Public Power District	1. 4.2.5.1 (And elsewhere in the standard) Please define auxiliary tripping relays. 2. 4.2.5.5 Do station "system connected" service transformers that do not supply house load for the generating unit, other than during start up or emergency conditions, fall under this clause? If so, can these transformers be eliminated if the house load can be back-fed from "generator connected" service transformer switchgear? What if there are redundant "system connected" feeds? 3. R1 1.4 Clarification requested. This wording would suggest all battery activities fall under Table 1.a. exclusively. 4. R4 4.3 Does initiation of activities require documentation, or is inclusion of "initiation" in the testing procedure sufficient evidence? 5. Tables 1b &1c: Suggestion: If at all possible, combine and simplify. The number of sub clauses and nuances that are being described in these sections (with little change to interval or procedures for that matter) is overwhelming. These two tables are setting RE's and System Owners up for making errors. Implementation and auditability should be the focus of this standard, SIMPLIFY. 6. SPS - Does the output signal need to be verified, or does the actual expected action need to be verified. Actual expected action would affect electrical generation production for NPPD's SPS.
Response: Thank you for your comments. 1. Please see FAQ II.4.C, II.4.D, II.4.E, II.4.F, II.4.G, and Sections 2.4 and 15.3 of the Supplementary Reference document for discussion regarding auxiliary relays. 2. The "load" being served by the station service transformer may be essential to operation of the generating plant, and therefore is not	

Organization	Question 7 Comment
the same as general distribution system load. Therefore, the SDT believes that these system components must remain within the Applicability section of the Standard. This is not affected by redundancy. 3. The Tables have been completely revised in consideration of your comment. Please see the new Table 1-4 for these activities. 4. As indicated in Measure M4, the SDT believes that documentation such as work orders, etc., is necessary. 5. The Tables have been completely revised. **6.** The draft Standard requires that the expected action is verified. This may be conducted in overlapping segments, and a simulation may be sufficient to verify in some cases.	
CenterPoint Energy	CenterPoint Energy believes the proposed Standard is overly prescriptive and too complex to be practically implemented. An entity making a good faith effort to comply will have to navigate through the complexities and nuances, as illustrated by the extensive set of documents the SDT has provided in an attempt to explain all the requirements and nuances. The need for an extensive “Supplementary Reference Document” and an extensive “Frequently Asked Questions Document”, in addition to 13 pages of tables and an attachment in the standard itself, illustrate that the proposal is too prescriptive and complex for most entities to practically implement. CenterPoint Energy is opposed to approving a standard that imposes unnecessary burden and reliability risk by imposing an overly prescriptive approach that in many cases would “fix” non-existent problems. To clarify this point, CenterPoint Energy is not asserting that maintenance problems do not exist. However, requiring all entities to modify their practices to conform to the inflexible approach embodied in this proposal, regardless of how existing practices are working, is not an appropriate solution. Among other things, requiring entities to modify practices that are working well to conform to the rigid requirements proposed herein carries the downside risk that the revised practices, made solely to comply with the rigid requirements, degrade reliability.
Response: Thank you for your comments. The SDT has extensively revised the Tables and the Standard in efforts to simplify and remove complexity. FERC Order 693 and the approved SAR for this project directed the SDT to establish both maximum maintenance intervals and minimum maintenance activities within the revised Standard.	
BGE	1. Comment 7.1. The standard, FAQs, and supplementary reference all make references to upkeep

Organization	Question 7 Comment
	and include in "upkeep" changes associated with manufacturer's service advisories. The FAQs include statements that the entity should assure the relay continues to function after implementation of firmware changes. This statement is uncontestable as general principle but is problematic in its inclusion in an enforceable standard because there is no elaboration on what the standard expects, if anything, as demonstration of an entity's execution of this responsibility. PRC-005-2 appropriately focuses on implementation of time-based, condition based, or performance based PSMPs; but addressing service advisories does not fit well with any of these ongoing preventive maintenance activities. It is instead episodic, more like commissioning after upgrades, or corrective maintenance work generated by condition-based alarms or anomalies discovered by analyzing operations. The standard appropriately steers clear of imposing requirements for these latter responsibilities as long as execution of an ongoing maintenance program is being demonstrated. BGE recommends that implied inclusion of service advisories should be removed from the standard and supporting documents. 2. Comment 7.2 R1.1 Requires the identification of all protection systems components. But it provides no elaboration on the level of granularity expected or acceptable means of identification. It is unlikely that the SDT expected the unique identification of every discrete component down to individual test switches or dc fuses. In the case of current transformers, several of which, or even dozens of which may be connected to a single relay there is no apparent reliability benefit that comes from indentifying them uniquely so long as it is proven that a protection system is receiving accurate current signals from the aggregate connection. (It may be argued that the revised definition of "protection systems" eliminates the need to include CT's under R1.1 but that's just one interpretation.) Some discrete components of communication systems may exist in an environment that is not owned by or known to the protection system owner. Additionally all protection system components may be indentified in documents that are current and maintained but not in the form of a specific searchable list that is limited to components that are within the scope of PRC-005. Examples may be indexed engineering drawings that indentify relays and other components for each protection systems or scanned relay setting and calibration documents that are current but not attached to searchable metadata. It is unclear whether or not these would be considered acceptable identification meeting R1.1. If they are not then the implementation plan for R1 is in all probability unachievable. BGE requests that the SDT provide more elaboration on R1.1 in the standard and in

Organization	Question 7 Comment
	the supporting documents. 3. Comment 7.3 For clarity footnote 1 to R1 which excludes devices that sense non-electrical signals should explicitly say that the auxiliary relays, lockout relays and other control circuitry components associated with such devices are included. The matter is well-addressed in the FAQ's but could easily be misunderstood if not included here.
Response: Thank you for your comments. 1. "Upkeep" has been removed from the definition of Protection System Maintenance Program, and from the Supplementary Reference and FAQ documents. 2. Requirement R1, part 1.1, has been revised to state, "Address all Protection System component types." 3. The SDT believes that these components are clearly included within the scope of dc control circuits.	
WECC	1. Compliance believes it will be difficult to demonstrate compliance when an entity chooses Condition Based Level 2 or Level 3 maintenance as the details of the requirements are still open to interpretation. The FAQ has answers to specific questions that are multiple choices. 2. Breaking down this standard into this level of granularity requires supplementary documents to understand it and for auditors to understand how to determine compliance. Industry standards are specific to equipment types and should be allowed to set intervals and maintenance tasks rather than a one-size fitting all approach.
Response: Thank you for your comments. 1. The Tables have been completely revised to clarify the monitoring attributes and related intervals and activities. 2. FERC Order 693 and the approved SAR for this project directed the SDT to establish both maximum maintenance intervals and minimum maintenance activities within the revised Standard.	
Constellation Power Generation	1. Constellation Power Generation does not agree with the changes to Voltage and Current Sensing inputs to protective relays in Table 1a. It is inferring that the only way to complete testing on these components to satisfy NERC is to complete online testing, which is dangerous and does not improve

Organization	Question 7 Comment
	the reliability of the BES. In fact, it can be argued that it decreases the reliability of the BES. The verbiage should be changed back to what was originally proposed to allow for offline testing. 2. Furthermore, Constellation Power Generation does not agree with several of the inclusions of generator Facilities in this standard. For example, in 4.2.5.1, the proposed standard looks to include any components that can trip the generator. At a nuclear facility, this could include protection of motors at the 4 kV level that may trip the generator due to NRC regulated safety issues. This should not fall under NERC jurisdiction. 3. The inclusion of station service transformers is another inclusion that should not be in this standard. There is no difference between a station service transformer and a transformer serving load on the distribution system. This has no impact on the BES, which is defined as the system greater than 100 kV. 4. Additionally, CPG has concerns regarding the vague language of R1.1, which requires the identification of all protection systems components. It provides no elaboration on the level of granularity expected or acceptable means of identification. It is unlikely that the SDT expected the unique identification of every discrete component down to individual test switches or dc fuses. In the case of current transformers, several of which, or even dozens of which may be connected to a single relay there is no apparent reliability benefit that comes from identifying them uniquely so long as it is proven that a protection system is receiving accurate current signals from the aggregate connection. (It may be argued that the revised definition of “protection stems” eliminates the need to include CT’s under R1.1 but that’s just one interpretation.) Some discrete components of communication systems may exist in an environment that is not owned by or known to the protection system owner. Additionally all protection system components may be identified in documents that are current and maintained but not in the form of a specific search-able list that is limited to components that are within the scope of PRC-005. Examples may be indexed engineering drawings that identify relays and other components for each protection systems or scanned relay setting and calibration documents that are current but not attached to search-able meta data. It is unclear whether or not these would be considered acceptable identification meeting R1.1. If they are not then the implementation plan for R1 is in all probability unachievable. 5. CPG requests that the SDT provide more elaboration on R1.1 in the standard and in the supporting

Organization	Question 7 Comment
	documents. In that vein, to clarify footnote 1 to R1 which excludes devices that sense non-electrical signals, it should explicitly say that the auxiliary relays, lockout relays and other control circuitry components associated with such devices are included. The matter is well-addressed in the FAQ's but could easily be misunderstood if not included here. 6. Lastly, Constellation Power Generation would like to voice concern over the expedited process in which this standard is being developed. Voting within a week of submitting comments does not leave enough time for the drafting team to thoroughly vet through the issues and identify much needed changes, let alone implement them.
Response: Thank you for your comments. 1. The intent of the cited section is to provide examples of how an entity might perform the testing. Any examples listed in either of the supporting documents should be looked upon as suggestions; these suggestions are not considered to be a complete list of the methods available. To the contrary, the Standard and the supporting documents were written considering that there are many ways to achieve a good test. Leeway is certainly available in how an entity complies with the Standard as the maintenance activities generally specify "what" must be achieved but not "how" an entity achieves it. Please see FAQ II.3.D. 2. FAQ III.2.A specifies that relays that trip breakers serving station auxiliary loads such as fans, pumps, and fuel handling equipment need not be included in the program even if loss of those loads could result in the tripping of the generator. 3. The "load" being served by the station service transformer may be essential to operation of the generating plant, and therefore is not the same as general distribution system load. Therefore, the SDT believes that these system components must remain within the Applicability section of the Standard. 4. Requirement R1, part 1.1, has been revised to state, "Address all Protection System component types." 5. Requirement R1, part 1.1, has been revised to state, "Address all Protection System component types." The SDT believes that the components associated with devices that sense non-electrical signals are clearly included within the scope of dc control circuits. 6. This Standard has been designated for an expedited process in order to achieve approval in the minimum time possible.	
Pepco Holdings, Inc. - Affiliates	Dates of the Supplemental Reference Documents in Section F of the standard need to be updated. 1. The word "calendar" is used widely to define month and year intervals. Sometimes causes

Organization	Question 7 Comment
	confusion, need definition/examples. 2. The level 2 table regarding Protection Station dc supply states that level 1 maintenance activities are to be used, but then goes on to give a list of Maintenance Activities that don't match those in level 1. Which activities shall we use? Same situation for Station DC Supply (battery is not used) where the 18 month interval is missing. 3. Req 1.1: "All Components" wording should say something like all components covered in our plan
Response: Thank you for your comments. 1. Section 8.4 of the Supplementary Reference document provides an example to assist in this determination. A "calendar year" is a single number year on the Gregorian calendar; a calendar month is any one of the twelve months within a single calendar year. 2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. 3. Requirement R1, Part 1.1, has been revised to state, "Address all Protection System component types."	
SERC Protection and Control Sub-committee (PCS)	1. Descriptors in the "type of the protection system component" column need to be consistent between 1A, 1B and 1C. 2. Also, in the tables, please clarify "complete functional trip test" for UVLS and UVLS trip tests since the breaker is not being tripped. Facilities Section 4.2.1 "or designed to provide protection for the BES" needs to be clarified so that it incorporates the latest Project 2009-17 interpretation. The industry has deliberated and reached a conclusion that provides a meaningful and appropriate border for the transmission Protection System; this needs to be acknowledged in PRC-005-2 and carried forward. 3. We commend the SDT for developing such a clear and well documented second draft. The SDT considered and adopted many industry comments on the first draft. It generally provides a well reasoned and balanced view of Protection System Maintenance, and good justification for its maximum intervals. The SERC Protection & Control Subcommittee generally agrees that this second draft will be beneficial to BES reliability.

Organization	Question 7 Comment
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. 2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 3. Thank you for your comment.	
Dynegy Inc.	For protection system component verification, flexibility is needed subsequent to a system event to allow the analysis of a protection system operation to be utilized as a protection system component verification. We believe this flexibility is needed and should be incorporated in Requirement R4.
Response: Thank you for your comments. Operational results, if desired by an entity, MAY be used to meet maintenance requirements to the degree that they verify, etc., the relevant performance. The entity must determine if their use is effective.	
MidAmerican Energy Company	1. From the compliance registry criteria for generator owner/operator and the language in 4.2.5.3 it is implied that the intent is that protection systems for individual generators less than 20 MVA would not be covered by PRC-005. To make this clear in the PRC-005-2 standard, the following footnote to section 4.2.5.3 is recommended: Protection systems for individual generating units rated at less than 20 MVA in aggregated generation facilities are not included within the scope of this standard. The Request for Interpretation of a Reliability Standard submitted March 25, 2009 indicates that a protection system is only subject to the NERC standards if the protection system interrupts the BES and is in place to protect the BES. The following changes are recommended to clarify this in the standard: A.3. Purpose: To ensure all transmission and generation Protection Systems protecting and affecting the reliability of the Bulk Electric System (BES) are maintained. A.4.2.1. Protection Systems applied on, or and designed to provide protection for the BES.B.R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a PSMP for its Protection Systems that use measurements of voltage, current, frequency and/or phase angle to determine anomalies and to trip a portion of the BES and that are applied on, or and are designed to

Organization	Question 7 Comment
	provide........ 2. FERC Order 693 includes the directive that “testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System”. If unanticipated conditions (e.g. force majeure) of the bulk-power system do not allow outages to complete protection system maintenance as required by the standard without compromising the reliability of the system delay of the particular maintenance activity should be allowed. This provision should be included in the standard in R4.
Response: Thank you for your comments. 1. This is an issue for your regional BES definition. The SDT has drafted the Standard to apply to all NERC entities with due regard for the applicable BES definition. 2. “Grace periods” within the Standard are not measurable, and would probably lead to persistently increasing intervals. However, an entity may establish an internal program with grace-period allowance, as long as the entire program (including grace periods) does not exceed the intervals within the Standard.	
Southern Company Transmission	1. General FAQ1) Attached is an elementary drawing showing a typical transmission line relay protection scheme utilizing SEL-351S and SEL-321 microprocessor relays. Does this qualify as partially monitored control circuitry? See pdf file Control Elementary_1-07-13 & Control Elementary_2-07-13in email documentation sent to Al McMeekin. If not, and this is an unmonitored circuit, what would be the appropriate maintenance interval (6 years or 12 years) for the Control and Trip Circuits from page 9 of PRC-005-2? The description of the two choices is ambiguous See pdf file PRC-005-2_clean_2 010June8.pdf in email documentation sent to Al McMeekin. If not, what would it take to make this circuit partially monitored (including inputs)? 2) Table 1a, page 9, row 2 (Voltage and Current Sensing Inputs) Question - Does this mean secondary quantities from CT’s and VT’s only? If so, please consider changing the wording from “Voltage and Current Sensing Inputs” to “CT and VT secondary quantities”. 3) Table 1a, page 9, row 3 (Control and trip circuits with EM contacts)Question - Does "electromechanical trip or auxiliary contacts" mean EM protective relay outputs and EM tripping/lockout tripping contacts only? Or does it also include any part of the trip circuitry such as

Organization	Question 7 Comment
	cutout switch contacts and breaker trip coils plus associated aux. breaker contacts. For example, the schematic with a microprocessor relay described in the first bulleted item could be considered an unmonitored EM control circuitry (6 year interval). Is this because of the mechanical breaker aux contacts, breaker maintenance switch, and FT-1 test switch? If so, how could any control circuitry fall in the solid state trip contacts category (12 year interval)? 4) Table 1a, page 9, rows 3, 4, 5, 6 - Please consider rewording these to make it clear where control schemes with MP relays that do have trip coil / circuit monitors but don't meet the Partially Monitored requirements fit. (Does this type scheme fit in the 6 year trip test category or the 12 year category?) 5) Table 1a, page 12, row 1 - The maintenance requirements are not the latest wording used for all other Protective Relays. Please consider changing for consistency. 6) Table 1b, page 13, row 1 (Protective Relays) - Line three of the maintenance activities requires us to check inputs and outputs. The last maintenance item is to verify correct operation of output actions that are used for tripping. Question - How is this different than the line three maintenance requirements to check inputs and "outputs"? 7) Table 1b, page 14, rows 1 and 2 - Consider combining these into one row. The maintenance intervals and maintenance activities are these same. Please specify what is required for UFLS and UVLS control schemes). 8) Table 1b, page 14, rows 1 - The first sentence is very general for a monitoring attribute. ("Monitoring of Protection System component inputs, outputs, and connections with reporting of monitoring alarms to a location where action can be taken.") Consider deleting this row or make it more specific. 9) Table 1b, page 14, row 2 [Control Circuitry (Trip Circuits) (except for UFLS/UVLS)]Question: Should there be a 12 year functional trip test requirement for this partially monitored control circuitry? Should this be added to Table 1b? 10) Table 1b, page 14, row 1 [Control Circuitry (Trip Circuits) (except for UFLS/UVLS)] - It states Monitoring of Protection System component inputs, outputs, and connections ... Question - what does "inputs" mean? There are Protection System components such as protective relays, control circuitry, station dc supply, associated communications systems, etc. Does this mean we must monitor inputs to any or all of these Protection System components? How would this be

Organization	Question 7 Comment
	accomplished? 11) Table 1c, page 18, row 4 - Should there still be a requirement to trip breakers by all trip coils every 6 years? Supplementary Reference Document 12) Question on Figure 1, page 27 - Box 1 denoting Protection Relays includes Aux devices, Test or Blocking Switches. The Aux devices Test or Blocking Switches should be part of Box 3 (Control Circuitry). Please correct or note accordingly. FAQ Document 13) On Page 30, please add an Example with Partially Monitored (Level 2) Control Circuit. 14) On the Control Circuit Decision Tree on page 36, the flow chart does not match the current Table 1 requirements. They match the previous version which is described in the first question of this document. We still propose leaving the flow chart on page 36 as is and change Table 1 to match the original requirements. 15) Please consider adding a diagram /elementary drawing of a Partially Monitored Control Circuit showing the trip output contacts, inputs, etc that must be monitored to meet the Monitoring Attributes / Requirements. A diagram showing an Unmonitored control scheme and what it would take to make it Partially Monitored would be helpful too. Additional General FAQ 16) PRC-005-2, R1 requires the Functional Entity to establish a Protection System Maintenance Program (PSMP). It is not clear if this standard establishes a specified frequency for reviewing and updating the PSMP itself or the PSMP criteria outlined in subparts 1.1 through 1.4. By comparison, EOP-005-1 System Restoration Plans, requires the Functional Entity to (a) have a restoration plan and (b) to review and update the restoration plan annually (see EOP-005-1, R1 and R2). This approach to a comprehensive and periodic review considers the PSMP as a whole and is independent of the specific maintenance methods (time-based, condition-based, or performance-based) and maintenance intervals for those respective methods. It is noted however that PRC-005 Attachment A mentions annual updates to the list of Protection System component. According to the

Organization	Question 7 Comment
	Attachment's subtitle, Criteria for a Performance-Based Protection System Maintenance Program, this annual update seems limited to performance-based maintenance and not inclusive of other maintenance methods. The recommendation is to evaluate the need for a periodic review of the PSMP as a whole. 17) R1, Criteria 1.1, and companion VSL. This Criterion requires the identification of all Protection System components. The VSL for R1 uses a percent-based approach to parse out different quantities of components across the four VSL categories. This implies that a Functional Entity must have the ability to put a numerical quantity on its various components and should be able to demonstrate within certain tolerances that its components are included (or counted). If the number of components within scope amount to hundreds or thousands of individual items, the PSMT SDT should consider the Functional Entities' ability to track and quantify the items for a compliance demonstration. If an entity is not able to reasonably quantify which components are in scope, demonstrating compliance on a percent-basis may prove difficult or impossible. Further review may indicate the need to reformat the VSL. Similar concerns are noted in other VSLs (R2, R3, and R4) and in Attachment A where percentage-of-components are mentioned. 18) R4 essentially requires the Functional Entity to implement its PSMP. R4 takes care to highlight the specific task of "identification of the resolution of all maintenance correctable issues." It is noted that other "identification tasks" are included as criterion for the PSMP in R1. If these tasks are all appropriately categorized as identification-type tasks, it may be more efficient to restructure the standard by incorporating this task into R1 with the other criteria. R4 could remain as a basic implementation requirement with more detail provided in subparts 4.1, 4.2, and 4.3. 19) Footnote No. 2 describes maintenance correctable issues and could be interpreted as a potential new term for inclusion in NERC's Glossary of Terms. The PSMT SDT should conduct further review of this terminology as a potential new Glossary term. 20) At R4, subpart 4.3, insert "design" such that it reads as follows: "Ensure that the components are within acceptable design parameters at the..." Also, this subpart duplicates Footnote No. 3 which describes "maintenance correctable issues" and was established in the main requirement R4 at Footnote No. 2.

Organization	Question 7 Comment
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 2. This portion of the definition of Protection System has been revised. Also, the Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3. 3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 4. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 5. The Tables have been rearranged and considerably revised to improve clarity. 6. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 7. The Tables have been rearranged and considerably revised to improve clarity. 8. The Tables have been rearranged and considerably revised to improve clarity. 9. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. 10. Some examples of input may include, but are not limited to: breaker fail initiate, start timer. This cannot be an all-inclusive list as any given scheme could have many variations. In short, if your scheme requires a specific input to function properly then you must have that input maintained; if your scheme has a specific output that must function then it must be maintained. If the input or output is used for a non-protective function (such as, but not limited to, Sequence-of-Events Recorder, alarm or indication) then it does not have to be maintained under this Standard. See Section 15.3 of the Supplementary Reference and FAQ II.2.L. 11. Yes. 12. The diagram is for illustrative purposes only, and is intended to demonstrate all devices which need to be included within a PSMP. Box 1 shows the cited devices as being within the relay panel, and makes no distinction regarding what specific type of Protection System component is being addressed. The preceding Table has been revised to avoid this conclusion. 13. The Tables have been revised to remove descriptions of various levels of monitoring. 14. The decision trees have been removed. 15. The Tables have been revised to remove descriptions of various levels of monitoring.	

Organization	Question 7 Comment
16. The expectation is that an entity's PSMP will be current. No periodicity is provided. However, in Attachment A, the performance-based program necessarily requires an ongoing review of the program to assure that it is still relevant. 17. Requirement R1, part 1.1, has been revised to state, "Address all Protection System component types." 18. The SDT believes that the identification of maintenance-correctable issues is properly an issue for <u>implementation</u> of the PSMP, not establishment of the PSMP. 19. The referenced footnote has been removed and a new definition established for this Standard only. 20. The SDT disagrees. The acceptable parameters for a specific application may not be identical to the design parameters for the component.	
FirstEnergy	Implementation Plan a. We do not support the 3 month implementation timeframe for Requirement 1. For many entities, it will take some time to develop a sound PSMP that meets the new PRC-005-2 standard. We suggest a 12 month implementation which we believe is more logical and in alignment with the implementation timeframe for Protection System Components with maximum allowable intervals of less than 1 year, as established in Table 1a. b. Although we support the implementation timeframes for Requirements R2, R3, and R4, we do not support the required periodic percentages of protections systems to be completed. There could be numerous reasons where an entity has to adjust its program schedule which could lead to noncompliance with these percentage milestones. We suggest simply requiring 100% completion of the maintenance per the maximum maintenance intervals. Alternatively an entity should have the flexibility to indicate they have fully transitioned to the new standard during the early stages of the implementation plan if their existing maintenance practices meet or exceed the standards minimum expectations. Doing so should negate the need to produce the "% complete" implementation status.
Response: Thank you for your comments. a. The Implementation Plan has been modified in consideration of your comment. b. The SDT disagrees and feels that a "phased" Implementation Plan is appropriate. The Implementation Plan has been revised to	

Organization	Question 7 Comment
	clarify that the percentages are minimums, not absolute.
American Transmission Company	1. It is appreciated that the SDT is attempting to provide options for maintenance and testing programs. Practically speaking, it will be difficult to perform any type of program outside of Time-Based Maintenance (TBM). Too many circuits are a mix of technology. For example, a line may have microprocessor relays for detecting and tripping line faults, but the bus differential lockout could also trip the line breaker. One may be partially monitored and the other unmonitored. It will force the utility to perform maintenance at the shorter of the maintenance cycles. Additional time and cost will be required to organize and switch out the applicable equipment for the outage, approximately doubling the cost associated with performing these trip tests. When entities are required to maintain tens of thousands of these devices, the simplest approach will be to revert to TBM. ATC does not support the existing 2nd Draft of PRC-005-2 Standard because it is our opinion that: o There is a high probability that system reliability will be reduced with this revised standard. o The number of unplanned outages due to human error will increase considerably. o Availability of the BES will be reduced due to an increased need to schedule planned outages for test purposes (to avoid unplanned outages due to human error). o To implement this standard, an entity will need to hire additional skilled resources that are not readily available. (May require adjustments to the implementation timeline.) o The cost of implementing the revised standard will approximately double our existing cost to perform this work. 2. ATC requests that relevant reliability performance data (based on actual data and/or lessons learned from past operating incidents, Criteria for Approving Reliability Standards per FERC Order 672) be provided to justify the additional cost and reliability risks associated with functional testing. 3. Under a Performance-Based Program, what happens if the population of components drops below 60 (as all will eventually)? Is there an implementation period to default to TBM? 4. Are the internal relays and timers associated with a circuit breaker included as part of the protection scheme? In the Independent Pole Operation breakers (IPO), there are various internal schemes built to protect for pole discordance (one pole open, two closed, event measured over time frame

Organization	Question 7 Comment
	(milliseconds)), these schemes may re-trip the breaker, initiate breaker failure protection or trip a bus lock out relay. In DC control schemes fuses and panel circuit breakers protect for wiring faults. Do these devices need to be tested? Is there an obligation to test the distribution circuit breakers for correct operation points? Is there an obligation to replace fuses after a defined time period?
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see the new Tables. 2. The Standard does not preclude an entity from largely utilizing other methods of verification, although functional testing may be the easiest to achieve. 3. The entity must revert to TBM if the population falls below 60. There is no implementation period; the SDT believes that the annual PBM review will alert the entity that the population is nearing 60, and allow the entity to react to the diminishing component population accordingly. 4. Only those control circuit components necessary for proper Protection System operation are included. As noted, many breakers have numerous other internal auxiliary functions (gas pressure, etc.) that are not relevant. A purely-functional test may address many of the issues cited. There is no obligation to test either distribution circuit breakers or dc panel fuses.	
NERC Staff	NERC staff is pleased with the current iteration of this standard. The staff understands that while PRC-005-2 has historically been the most frequently violated standard, it has mostly been due to documentation issues. The standard has not been much of a heavy hitter in causal or contributive aspects, and with respect to relay operations, there have been very few times that lack of maintenance has been the problem. 1. NERC staff does propose a slight change to 4.2.5.1. The concern is that 4.2.5.1 could be interpreted to apply to devices that protect the generator as opposed to those that protect the Bulk Electric System. The suggested language is as follows: “Protection System components that act to trip generators that are part of the BES, either directly or via generator lockout or auxiliary tripping relays.” 2. Additionally, staff suggests some changes to R1. In that requirement, the PSMP covers “Protection Systems that use measurements of voltage, current, frequency and/or phase angle to determine

Organization	Question 7 Comment
	anomalies and to trip a portion of the BES...” It probably would be better if the list was limited to voltage and current or if the list was replaced with electrical quantities. The former would be okay since voltage and current are the only two electrical quantities that relays measure directly. To remove ambiguity, the most inclusive way to rephrase this is probably the latter alternative, to change the requirement to, “...that use measurements of electrical quantities to determine anomalies...” 3. Finally, Footnotes 2 and 3 (in Requirement 4) are identical. Unless that’s intentional, one should be removed. (And note that Footnote 2 is missing a period.)
Response: Thank you for your comments. 1. The essence of your suggestion is already addressed within 4.2.5 itself. 2. The definition of Protection System has been revised to address your suggestion. 3. The footnotes have been removed.	
MEAG Power	No comment.
Exelon	1. Nuclear generators are licensed to operate and regulated by the Nuclear Regulatory Commission (NRC). Each licensee operates in accordance with plant specific Technical Specifications (TS) issued by the NRC which are part of the stations’ Operating License. TS allow for a 25% grace period that may be applied to TS Surveillance Requirements. Referencing NRC issued NUREGs for Standard Issued Technical Specifications (NUREG-143 through NUREG-1434) Section 3.0, "Surveillance Requirement (SR) Applicability," SR 3.02 states the following: "The specified Frequency for each SR is met if the Surveillance is performed within 1.25 times the interval specified in the Frequency, as measured from the previous performance or as measured from the time a specified condition of the Frequency is met." The NRC Maintenance Rule (10 CFR 50.65) requires monitoring the effectiveness of maintenance to ensure reliable operation of equipment within the scope of the Rule. Adjustments are made to the PM (preventative maintenance) program based on equipment performance. The Maintenance Rule

Organization	Question 7 Comment
	program should provide an acceptable level of reliability and availability for equipment within its scope. The NRC has provided grace periods for certain maintenance and surveillance activities. Exelon strongly believes that SDT should consider providing this grace period to be in agreement and be consistent with the NRC methodology. Not providing this grace period will directly affect the existing nuclear station practices (i.e., how stations schedule and perform the maintenance activities) and may lead to confusion as implementing dual requirements is not the normal station process. Nuclear generating stations have refueling outage schedule windows of approximately 18 months or 24 months (based on reactor type). If for some reason the schedule window shifts by even a few days, an issue of potential non-compliance could occur for scheduled outage-required tasks. The possibility exists that a nuclear generator may be faced with a potential forced maintenance outage in order to maintain compliance with the proposed standard. For the requirements with a maximum allowable interval that vary from months to years (including 18 Months surveillance activities), the SDT should consider an allowance for NRC-licensed generating units to default to existing Operating License Technical Specification Surveillance Requirements if there is a maintenance interval that would force shutting down a unit prematurely or face non-compliance with a PRC-005 required interval. Therefore, at a minimum, maintenance intervals should include an allowance for any equipment specifically controlled within each licensee's plant specific Technical Specifications to implement existing Operating License requirements if such a conflict were to occur. 2. PECO would like to have the implementation plan provide at least 1 year for full implementation of the new standard. This will provide adequate time for development of documentation, training for all personnel, and testing then implementation of the new process(es).

Response: Thank you for your comments.

1. The SDT understands that nuclear power plants are licensed and regulated by the NRC, has a general understanding of the role that plant Technical Specifications (TS) and associated Surveillance Requirements (SR) in the facilities' operating licenses, and has tried to be sensitive to potential conflicts between PRC-005-2 and NRC requirements.

Organization	Question 7 Comment
The SDT believes that the majority of components making up the protection systems for in-scope generating facilities as discussed in Section 4.2.5 of the Standard would be considered balance of plant equipment and, therefore, not subject to NRC-issued TS and associated SR requirements. While availability of plant auxiliary sources to the plant's safety related equipment is addressed by TS and associated SR requirements, these documents are focused on the effects that the availability of these transformers have on reactor safety rather than specifying maintenance and testing requirements for the Protection Systems for these transformers. The SDT recognizes that some battery systems may serve as a source of DC power to both reactor safety systems and to Protection Systems discussed in Section 4.2.5. The SDT acknowledges that there might be plant TS and SR applicable to these batteries. However, the SDT believes that the 3-month and 18-month inspection requirements called for in PRC-005-2 would be no more onerous than plant TS requirements for routine online safety system battery inspections and, furthermore, would not necessitate a plant outage. The SDT recognizes that the PRC-005-2 requirement for validating battery design capability via battery capacity testing would require a plant outage. However, it is the opinion of the SDT that the maximum allowed battery capacity testing intervals of not to exceed 6 calendar years for vented lead acid or NiCad batteries (not to exceed 3 calendar years for VRLA batteries) could easily be integrated within the plant's routine 18-month to 2-year interval refueling outage schedule. The SDT believes that PRC-005-2 is complementary to the NRC Maintenance Rule in that PRC-005-2 requirements allow for the leveraging of the entire electrical power industry experience in establishing minimum maintenance activities and maximum allowed maintenance intervals necessary to ensure reliable Protection System performance. Please see Supplemental Reference Section 8.4 for further discussion for the SDT's rationale for exclusion of grace periods. Please see FAQ IV.2.C for further discussion of impact of PRC-005-2 testing requirements on power plant outage schedules. The challenge of integrating PRC-005-2 testing requirements with a plant's outage schedule is not unique to nuclear plants. Finally, the SDT notes that an entity may build grace periods into its own PSMP as long as the maximum allowed time intervals of PRC-005-2 are not exceeded. If an entity wishes to build a 25% grace period into its program, it may do so by setting its program maintenance and testing intervals at <80% of the PRC-005-2 maximum allowable time interval. 2. The Implementation Plan has been modified in consideration of your comments.	
Hydro One Networks	1. Footnotes 2 and 3 on page 4 are identical. Delete footnote 3. 2. UFLS systems by design can suffer random failures to trip. It would make sense for a requirement to exist to perform maintenance on the UFLS relay as their failure to operate may affect numerous distribution level feeders. However maintenance on associated DC schemes connected to the

Organization	Question 7 Comment
	devices should only be done on the same frequency as maintenance on the relevant interrupting devices. Consideration should be given to exempting schemes that have a maintenance program in place on those distribution level devices from PRC-005 Standard-specified maintenance intervals. Such Standard-specified intervals could apply to interrupting devices that have no maintenance program in place.
Response: Thank you for your comments. 1. The footnotes have been removed. 2. The Tables have been rearranged and considerably revised to improve clarity, and many activities related to UFLS have been removed. Please see the new Tables.	
Progress Energy Carolinas	1. R1.1.1 states that “all” protection system components be identified. Does the term “all” refer to the major components identified in the Protection System definition (protective relays, communication systems, voltage and current sensing devices, station dc supply, and control circuitry) or does it include all sub-components (jumpers, fuses, and auxiliary relays used in dc control circuits and communication paths/wavetraps/tuners/filters)? We assume the former but request clarification. 2. Draft Implementation Plan for PRC-005-02: The phased implementation plan for R2, R3, and R4 seems reasonable. However, the three-month implementation plan for R1 seems extremely short. Utilities will have to change procedures, job plans, basis documents, provide training, and change intervals in their work tracking databases. In addition, if the utility wants to take advantage of the longer intervals allowed by partial monitoring, significant print work must be performed up front. 3. Descriptors in the type of the protection system column needs to be consistent between 1A, 1B and 1C. In the tables, please clarify “complete functional trip test” for UVLS and UVLS trip tests since the breaker is not being tripped.
Response: Thank you for your comments. 1. Requirement R1, Part 1.1, has been revised to state, “Address all Protection System component types.” 2. This portion of the Implementation Plan has been revised to twelve months in consideration of your comment.	

Organization	Question 7 Comment
3. The Tables have been rearranged and considerably revised to improve clarity. Please see the new Tables.	
Manitoba Hydro	1. Once the new Standard is approved, NERC must allow for a greater implementation stage and no further changes proposed for the foreseeable future. It does take a lot of resources for a Utility to make the required changes in maintenance frequency templates or type of maintenance required as per the proposed "Standard". 2. Regarding the use of the term “Calendar” (i.e. end of calendar year) for maximum maintenance interval. Our utility uses end of fiscal year as our cutoff date for completing maintenance tasks for a given year. It would be considerable work for us to have to switch to end of calendar year with zero improvement in our overall reliability. We suggest it be left up to each utility to define their calendar yearly maintenance cycle when all tasks for that year must be completed.
Response: Thank you for your comments. 1. The implementation period for Requirement R1 has been extended from 3 months to 12 months in consideration of your comments. 2. With the vast array of entities subject to compliance monitoring, it would be very difficult for the ERO to assess compliance for varying “years.” Additionally, the SDT understands that most compliance monitors currently request data on a calendar year basis when assessing compliance.	
Grant County PUD	PRC005-02 Comment We offer some comment for your consideration for incorporation into the Standard PRC-005-02 (draft) as presented in the May 27th 2010 PRC 005-02 “Standard Development Roadmap.” RE: Comment on the 2nd Draft of the Standard for Protection System Maintenance and Testing” 1) The term “The Protection System Maintenance Program” (Page 2) appears to be centered on the concept of maintaining specific components as stand alone objects, and therefore infers that the resultant documentation be organized in a similar fashion. Neither is optimal from a practical or a functional perspective. Many rational work practices combine components (example, meggering from the relay input test switch through the cables and the CTs) in the interest of minimizing circuit intrusion and human error. For this reason, such maintenance practices are superior from a reliability standpoint. The emphasis on “components” in the current draft is, at best, tangential to NERC’s

Organization	Question 7 Comment
	stated goal and purpose of PRC-005 to improve reliability. How would we fix this? We would insert the phrase “or Element”-as defined in NERC’s Glossary of Terms to include “one or more components / devices with terminals that measures voltage, current, frequency and/or phase angle” to determine anomalies and to trip a portion of the BES” immediately after any occurrence of the word “component” in each of the Requirements or in a Definition paragraph, intending it to be applied globally to R-1 through R4. This would foster the validity of maintenance activities being applied to aggregations of components - “Elements”-such as would occur during Verification of DC control circuitry or through the employment of fault data analysis. 2) Protection System Maintenance Program. The categorization of maintenance into 7 maintenance activities is welcomed as advancing practices which foster BES reliability. Likewise we find the clarifications denoted by superscripts 1 and 2 helpful. However....under C: MEASURES: M1, the last sentence of the paragraph provides: “For each protection system component, the documentation shall include the type of maintenance program applied (time based, etc), maintenance activities (1 or more of the 7 identified) and maintenance intervals.....” This measure goes beyond the requirements of the standard and should be revised consistent with the deletion of the previous R.1.1 as shown in track changes under the version 2 draft which had included the identification of the maintenance activity associated with each component. COMMENT: It should be apparent in reviewing the evidence that one or more of the 7 listed activity categories are represented. The proscription to explicitly call out these categories is thus redundant---the requirement being that at least one has to be identifiable in the program-and will cause unnecessary complications to the Entity and interpretation issues in the Compliance monitoring effort. We recommend that the words “maintenance activities” be removed from the last sentence in the paragraph pertaining to C: MEASURES: M1.We also believe it is unnecessary to restate the definition of “Protection System” in the Measure. 3) A fundamental incompatibility exists between NERC’s proposition of “maximum maintenance (time based) interval” and the typical CMMS PM generation algorithm. SPCTF members and regional compliance engineers have verbally represented that the “maximum maintenance interval” is a precise term “not to exceed-even by one day---” maximum, otherwise generating a fine-able Violation and that fixed intervals plus or minus a certain additional period of time to account for other operational exigencies are no longer going to be permitted. There is always an interval between the

Organization	Question 7 Comment
	time a CMMS PM is issued and its completion. The time interval between the issue date and the completion date is normally a period of time to allow maintenance staff to schedule their work in an orderly fashion. The maximum time based interval is fixed by the time period specified for issuance of the planned maintenance (PM) work order (e.g. every 3 years) and the defined period of time to complete the work (usually described as a percentage of the PM interval e.g. 25%). So predicating a PM issue date based on the last issue date plus a percentage of the interval time to complete the work is not inconsistent with a fixed time interval. Under the proposed tables, however, there is no accommodation for this predominate maintenance practice. Even if maintenance intervals were shortened to ensure that the required completion date as defined by program intervals does not exceed the NERC maximum interval as described in the tables, this will not be sufficient because auditors may conclude that the tables permit the use of only a single defined interval and not permit an additional defined period of time to schedule and complete the work. Remember, it is immaterial whether the Entity's interval is more stringent than the NERC maximum, a violation may occur if the maintenance is not performed within the Entity's maintenance interval, even if it is shorter than the NERC maximum. A precise maximum interval requires constant managerial intervention on the part of the Entity to ensure that operational exigencies do not cause violations on a component-by component (or element) basis. The shortened interval would tend to destroy the sense of rhythm and pattern which should be manifest in a time based program. Further, after one or more iterations, seasonal restrictions on outages begin to impinge requiring adjustments to be made to the Maintenance Program document to adjust the interval or maintenance activity. At best, it results in a clumsy way of doing business and requiring significantly more oversight into keeping the maintenance program document updated for presentation to auditors rather than focusing on prudent maintenance activities as desired by FERC Order 693. Auditing is not any more difficult if the Maintenance Program also specifies that a percentage of a fixed target / time interval is allowed to schedule and complete the work-as meeting the interval requirements of a time based maintenance program. This method allows for a fixed time for issuance of the work order and maintenance personnel some flexibility to schedule and complete their work within a defined period of time. We recommend to vote against adoption until some more workable solution is identified and disseminated, satisfying both the Compliance Authority and the affected Entities. Specifically, we recommend that the drafting team adopt "target" intervals with a +/- range of

Organization	Question 7 Comment
	acceptability, based on percentage or a fixed time per interval, which can be global for the Program or specific to the elements or components in question. The target intervals must be stated in the PSMP, the range of acceptability easily calculable and enforceable, and within the maximum intervals to be identified in the tables 1a, b, and c, satisfying compliance issues. This also allows the Entities to rationally plan their maintenance using existing CMMS technologies. 4) Within the Violation Security levels, we are aware of no activity by NERC to differentiate the relative criticality of components or Elements of the BES system. For example, protection system components or Elements in a regional switchyard may present a larger potential for disruption of the BES in the event of a mis-operation than does one associated with one generator among fifteen others and which is more electrically remote from and of less consequence to the BES. Unless and until this issue is addressed, both the PRC-005 maintenance and documentation will be less effective and more expensive than it could be. 5) PRC-005-02's proposed effective date is "See Implementation Plan." This is not adequate to provide regulated entities with appropriate notice of the Effective Date of PRC-005-2 standard. " 6) Additionally, NERC has not posted the "Implementation Plan" for comment in the same manner as the proposed standard and thus we are not able to comment on the schedule provided in the Plan. We understand that the retention and documentation cycles go back three years and that a regulated entity, depending on the effective date of this standard and the entity's audit cycle, will be audited to both PRC-005-1 and PRC-005-2 during the same audit period. Some further discussion should be given to allowing comment on the Implementation Plan because of the potential overlapping requirements during a single audit cycle.

Response: Thank you for your comments.

1. The draft Standard supports a variety of methods of designing the PSMP.
2. A definition of "Component" and "Component Type" has been added to the draft Standard. The SDT's intent is that this definition will be used only in PRC-005-2, and thus will remain with the Standard when approved, rather than being relocated to the Glossary of Terms. The Requirements and Measures have been modified to use these terms in a consistent manner. These defintions will assist in addressing your concern.

Organization	Question 7 Comment
3. This comment seems to suggest that a "grace period" should be permitted. "Grace periods" within the Standard are not measurable, and would probably lead to persistently increasing intervals. However, an entity may establish an internal program with grace-period allowance, as long as the entire program (including grace periods) does not exceed the intervals within the Standard. 4. Thank you for your comment. The VRFs address the reliability impact of the Requirements, while the VSLs simply address "how bad did you miss it?" 5. The Implementation Plan for Requirement R1 has been revised from 3 months to 12 months to address this comment. 6. The Implementation Plan was posted for comment, with a question on the comment form during the first posting. The Implementation Plan was not substantially revised for the second posting. During the implementation period, there will be some overlap between PRC-005-1 and PRC-005-2. An unattractive alternative would be to minimize the implementation period for PRC-005-2.	
Xcel Energy	1. R1.1 "Identify all Protection System Components" - does this mean that the PSMP must contain a "list"? Please explain what this means. If it is a list, then essentially it will be a dynamic database, not necessarily a "program" as defined in the PSMP 2. R1.3 "include all maintenance activities..." seems to be an indirect way of indicating that the entities PSMP must comply with the tables. Tables - the components related to DC Supply and battery are confusing. It the battery is the specific component then state "battery". If the charger is the specific component, then state "charger". As currently written, one must sort through all of the different "Station DC Supply" line items to figure out what is required.- 3. In tables 1b and above, it is written "no level 2 monitoring attributes are defined - use level 1 maintenance activities" but then maintenance activities are listed that don't match with Level 1 maintenance activities. Please clarify what exactly needs to be done if using Table 1 b and above.
Response: Thank you for your comments. 1. Requirement R1, Part 1.1, has been revised to state, "Address all Protection System component types." 2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4.	

Organization	Question 7 Comment
3. The Tables have been rearranged and considerably revised to improve clarity.	
Northeast Utilities	1. R1.1 It is not clear what would constitute “all Protection System components”. Suggest the addition of a definition for “Protection System components”.R1.4 Suggest revise to read: “all batteries or dc sources” 2. Table 1a vented lead acid -- “Verify that the station battery can perform as designed by evaluating ...” -- Please define evaluating, including: a. What is the basis for the evaluation? b. Is 5% 10% 20% etc acceptable? c. Where does baseline come from for older batteries? 3. Request clarification of 2.3 Applicability of New Protection System Maintenance Standards from Supplementary Reference. Specifically, please clarify if a functional trip test is needed to be performed on the distribution circuit breakers to protect the Bulk Electric System (BES) if these low side breakers are not part of the transmission path. (A diagram identifying the applicable breakers would be helpful in the Supplementary Reference)
Response: Thank you for your comments. 1. Requirement R1, Part 1.1, has been revised to state, “Address all Protection System component types”..(a) The basis is related to the variation from the baseline. Please see FAQ II.5.G and II.5.F. (b) This is determined by the entity based on the application. (c) The baseline can be provided by the battery manufacturer or the test equipment OEMs. **2.** The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5.	
South Carolina Electric and Gas	R1.1 states “Identify all Protection System Components”. To avoid confusion this should be clarified. It could be interpreted that discreet components must be individually identified. An example would be as individual aux relays used in the tripping path.
Response: Thank you for your comment. Requirement R1, Part 1.1, has been revised to state, “Address all Protection System component types”.	

Organization	Question 7 Comment
PacifiCorp	1. R1.1: Please clarify what the requirements for "identify" means. Does each component need to be "identified" in our maintenance system, or at least referenced in the maintenance program or labeled in the field??? 2. R4.3: Please provide guidance on what will be required to prove compliance that "maintenance correctable issues" have been identified and corrective actions initiated. 3. What is the implication of finding maintenance correctable issues as it relates to other requirements for no single points of failure? In other words, if during maintenance a relay is found to have failed, is there an acceptable time period under which we may operate the system without redundancy until a repair can be made? Similarly, if part of a redundant relay system is taken out of service for maintenance, may the facility it was protecting be left in service? If not, then is the implication that protection systems must be triple redundant in order to do relay maintenance on in service equipment? Otherwise facilities would always have to be removed from service to do relay maintenance. 4. Section D / 1.3: The data retention requirement for the two most recent performances of each maintenance activity is excessive. The requirement should be limited to the most recent or all activities since the last on-site audit. At the worse case an entity would have to retain records for up to 35 years for maintenance performed on a 12 year cycle. 5. Table 1a "Protective Relay" entry: The last maintenance activity is listed as "for microprocessor relays verify acceptable measurement of power system input values " for which a 6 year interval is provided". How is this different than the next item "Voltage and Current Sensing Inputs to Protective Relays and associated circuitry" which is on a 12 year interval?? Please clarify this. 6. Implementation Plan: This revised standard will drive significant revisions in existing maintenance programs. 3 months is not adequate time after approval to ensure compliance with R1. A minimum of 6 months should be utilized after regulatory approval. The Implementation plan requirements should also recognize that if the requirement to maintain records of the two previous maintenance tasks is implemented, it may not be possible to produce this information upon implementation. The implementation plan should be structured that the requirement to produce previous maintenance records should be phased in as the maintenance is performed. (ie. The requirement to produce two

<table>
<tr><th>Organization</th><th>Question 7 Comment</th></tr>
<tr><td></td><td>previous records for maintenance performed on a two year cycle should not be enforced until four years after implementation).</td></tr>
<tr><td colspan="2">Response: Thank you for your comments.
1. Requirement R1, Part 1.1, has been revised to state, “Address all Protection System component types”.
2. Various means may be used. One suggestion would be work orders that addressed the issue.
3. It is left to the entity to determine HOW to address maintenance-correctable issues. It is reasonable that an entity would do so in a manner that presents the least disruption to the system and considers the impact of the malfunctioning component on reliability.
4. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one, as well as data to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted Standard to establish this level of documentation. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1.
5. The Implementation Plan for Requirement R1 had been revised from 3 months to 12 months.</td></tr>
<tr><td>Springfield Utility Board</td><td>SUB is supportive of the intent behind the standard and appreciates the ability to provide input into this process.

1.The following is a repeat of the comment in Question #5 with regard to the supplemental reference.

SUB appreciates that Time Based, Performance Based, and Condition Based programs can be combined into one program. However it should be clear that a utility may include one, two or all three of these types of programs for each individual device type.

Currently the language reads:"TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System." The "and" requires all three to be combined if they are combined. SUB suggests the “and” be changed to "or" language.

Change:"TBM, PBM, or CBM can be combined for individual components, or within a complete Protection System."</td></tr>
</table>

Organization	Question 7 Comment
Response: Thank you for your comments. Please see our response to your comment in Question 5.	
The Detroit Edison Company	1. Suggest that the implementation plan for R1 (PSMP) be changed to 12 months. 2. The statement in R1.1, “Identify all Protection System components” regarding the PSMP should be clarified. Is a complete list of every “component” of each specific protection system required to be included in the PSMP?
Response: Thank you for your comments. 1. The Implementation Plan for Requirement R1 has been revised from 3 months to 12 months. **2.** Requirement R1, Part 1.1, has been revised to state, “Address all Protection System component types.”	
Long Island Power Authority	1. Table 1a under Maintenance Activities for Control and trip circuits with unmonitored solid-state trip or auxiliary contacts (UFLS/UVLS Systems Only) states: Perform a complete functional trip test that includes all sections of the Protection System control and trip circuit, including all solid-state trip and auxiliary contacts (e.g. paths with no moving parts), devices, and connections essential to proper functioning of the Protection System., except that verification does not require actual tripping of circuit breakers or interrupting devices. The word complete may be removed as it requires actually tripping the breakers. The sentence that tripping of the circuit breakers is not required contradicts with the word complete. 2. More specifics are required to spell out the adequate testing e.g. up to the lockout with the trip paths isolated etc. 3. Table 1a under Maintenance Activities for Station dc Supply (used only for UVLS or UFLS) states: Verify proper voltage of the dc supply. Is this requirement applicable to the distribution substations only? 4. Table 1a under Maintenance Activities for Station dc supply (battery is not used) - states Verify that the dc supply can perform as designed when the ac power from the grid is not present. - Please clarify this requirement.

Organization	Question 7 Comment
	5. Table 1a for Associated communications systems - specify the group for the applicability of this requirement. BPS,BES,UFLS etc. 6. Table 1a under Maintenance Activities for Associated communications systems states - Verify that the performance of the channel meets performance criteria, such as via measurement of signal level, reflected power, or data error rate. Why is this required? The requirement "Verify proper functioning of communications equipment inputs and outputs that are essential to proper functioning of the Protection System. Verify the signals to/from the associated protective relays seems sufficient to ensure reliability. 7. Table 1a under Maintenance Activities for Relay sensing for Centralized UFLS OR UVLS systems UVLS and UFLS relays that comprise a protection scheme distributed over the power system states: Perform all of the Maintenance activities listed above as established for components of the UFLS or UVLS systems at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the UFLS or UVLS components whose operation leads to that control action must each be verified. Clarify what is meant by overlapping segments? What is the specified interval? Is actual breaker tripping required?

Response: Thank you for your comments.

1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5.
2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4.
3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4.
4. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4.
5. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3.
6. Communications systems are subject to a variety of problems. The listed activities will detect many of these problems. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-2.
7. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1. Please see Section 8 of

Organization	Question 7 Comment
	the Supplementary Reference document regarding “overlapping segments.”
American Electric Power	1. The "Supplementary Reference" and the "Frequently-Asked Questions" document should be combined into a single document. This document needs to be issued as a controlled NERC approved document. AEP suggests that the document be appended to the standard so it is clear that following directions provided by NERC via the document are acceptable, and to avoid an entity being penalized during an audit if the auditor disagrees with the document’s contents. 2. NiCAD batteries should not be treated differently from Lead-Acid batteries. NiCAD battery condition can be detected by trending cell voltage values. Ohmic testing will also trend battery conditions and locate failed cells (although will usually lag behind cell voltages). A required load test is detrimental to the NiCAD manufacturer's business, and will definitely hurt the NiCAD business for T&D applications. Historically NiCADs may have been put into service because of greater reliability, smaller space constraints, and wider temperature operation range.”Individual cell state of charge” is a bad term because it implies specific gravity testing. Specific gravity cannot be measured automatically (without voiding battery warranty or using an experimental system), and when it is measured, it is unreliable due to stratification of the electrolyte and differing depths of electrolyte taken for samples. “Battery state of charge” can be verified by measuring float current. Once the charging cycle is over the battery current drops dramatically, and the battery is on float, signaling that the battery has returned to full state of charge. This is an appropriate measure for Level 3 monitoring as float current monitoring is a commercially viable option and electrolyte level monitoring is not. 3. In Table 2b, why is Ohmic testing required if the battery terminal resistance is monitored? Cell to cell and battery terminal resistance should not be monitored because they will be taken in 18 month intervals. This further supports the argument that the battery charger alarms would be sufficient for level 2 monitoring, while keeping an 18 month requirement for Ohmic testing, electrolyte level verification, and battery continuity (state of charge). Automatic monitoring of the float current should be sufficient for level 3 monitoring as it gives state of charge of the string, and battery continuity (detect open cells). Shorted cells will still be found during the Ohmic testing and a greater interval is sufficient to locate these problems.

Organization	Question 7 Comment
Response: Thank you for your comments. 1. The SDT disagrees that the documents should be combined. The Supplementary Reference is a holistic presentation of rationale and basis for the various elements of the Standard – discussing mostly the "what" behind the requirements. The FAQ, on the other hand, presents responses to specific frequently-asked questions, and, as such, offers more-focused advice on specific subjects, and is more of a how-to/example discussion. The FAQ is primarily a means of capturing some of the most prevalent comments offered on the Standard by various entities, with the SDT's response. The SDT believes that the format of the FAQ is a more effective means of presenting the included information than it would be to include this information within the text of the Supplementary Reference document. The Standards Committee has a formal process for determining whether to authorize posting a reference document with an approved standard. That process is posted on the Standard Resources web page – here is a link to the procedure: http://www.nerc.com/files/SC_Process_Approve_Supporting_References_Approved_10Mar08.pdf 2. The SDT believes that, since the IEEE Stationary Battery Committee has determined that VRLA batteries and Ni-Cad batteries are different enough to require separate IEEE Standards (IEEE 1188 and IEEE 1106, respectively), these battery technologies are different enough to be treated separately within PRC-005-2. The SDT has drawn upon these IEEE Standards, as well as other sources (EPRI, etc) to develop the Requirements of PRC-005-2. The trending activity cited has not been shown to be effective for Ni-Cad batteries (see FAQ II.5.G), and thus a performance tests must be performed; the performance test may take many forms. The Tables have been rearranged and considerably revised to improve clarity, and all references to specific gravity have been removed. Please see new Table 1-4. Determining the "state of charge" by monitoring the float voltage may be relevant to the overall station battery, but does not provide an indication of the condition of individual cells as required within the new Table 1-4. 3. Battery terminal resistance shows the condition of the external connections, but reveals nothing regarding the internal condition of the individual cells. Measuring the internal cell/unit resistance provides an opportunity to trend the cell condition over time by verifying the electrical path through the electrolyte within the battery. The ohmic testing is not intended to look for open cells/units, but instead at the ability of the individual cell/unit to perform properly. The new Table 1-4 clarifies that, if the electrolyte level is monitored, the internal ohmic testing need only be performed every six years. Please see FAQ II.5.B, II.5,C, and II.5.D for a discussion about continuity.	
JEA	The current interpretation by the SDT of partially monitored is set at a higher bar than most utilities use in their current designs today. We all wish to take advantage of the microprocessor relays and their renowned and improved monitoring capability. If TC1 is monitored by primary relay A and TC2 is

Organization	Question 7 Comment
	monitored by primary relay B, and these relays in turn monitor their DC supplies, the vast majority of the system is monitored - (partially monitored), including all the control cable out to the remote breakers and their trip coils. To add to this some additional contacts within the scheme, located very near the primary relays, is extending the partially monitored bar to a higher level than most designs incorporate today. If you know that 98% of the DC control system is monitored - isn't that partially monitored? Please consider changes to the SDT's current view of a partially monitored protection systems.
Response: Thank you for your comments. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 through 1-5.	
Arizona Public Service Company	1. The generator Facilities subsections 4.2.5.1 through 5 are too prescriptive and inconsistent with sections 4.2.1 through 4. Recommend this section be limited to description of the function as in the preceding sections. 2. Clarification is needed on how the “Note 1” in Table 1a, which appears to be used in to define a calibration failure would be used in Time Based Maintenance. In PRC-005-2 Attachment A: Criteria for a Performance-Based Protection System Maintenance Program, a calibration failure would be considered an event to be used in determining the effectiveness of Performance Based Maintenance. It is unclear in how it will be used in time based maintenance.
Response: Thank you for your comments. 1. The SDT believes that transmission lines, UFLS, UVLS, and SPS are clear without additional granularity, but that the additional granularity regarding generation plants is necessary. This is illustrated by numerous questions regarding “what is included for generation facilities?” relative to PRC-005-1. 2. The Tables have been rearranged and considerably revised to improve clarity. In addition, the Note was removed, and Requirement 4 has been considerably revised.	
Pacific Northwest Small Public Power Utility Comment Group	1. The level 2 table regarding Protection Station dc supply states that level 1 maintenance activities are to be used, but then goes on to give a list of Maintenance Activities that don’t match those in level 1. Which activities shall we use? Same situation for Station DC Supply (battery is not used) where the

Organization	Question 7 Comment
	18 month interval is missing. 2. IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months due to storms and outages must set a target interval of two months thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, we also suggest that all intervals expressed as 3 calendar months be changed to 4 calendar months. 3. We are concerned over R1.1, where all components must be identified, without a definition for the word component or the granularity specified. While the FAQ gives a definition, and allows for entity latitude in determining the granularity, the FAQ is not part of the standard. We believe this will allow REs to claim non-compliance for every three inch long terminal jumper wire not identified in a trip circuit path. We suggest that the FAQ definitions be included within the standard.
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. 2. The SDT disagrees. The entity should schedule routine inspections to complete the specified activities within the specified 3-month interval. 3. Requirement R1, Part 1.1, has been revised to state, "Address all Protection System component types."	
PNGC Power	The level 2 table regarding Protection Station dc supply states that level 1 maintenance activities are to be used, but then goes on to give a list of Maintenance Activities that don't match those in level 1. Which activities shall we use? Same situation for Station DC Supply (battery is not used) where the 18 month interval is missing.
Response: Thank you for your comments. The Tables have been rearranged and considerably revised to improve clarity.	
MRO's NERC Standards Review Subcommittee	1. The NSRS does not support the existing 2nd Draft of PRC-005-2 Standard because it is our opinion

Organization	Question 7 Comment
(NSRS)	that: o There is a high probability that system reliability will be reduced with this revised standard. o The utility industry is in the business of keeping the lights on, but these requirements will force the industry to take customers out of service in order to fulfill these requirements. A possible solution is to increase the test intervals, set performance targets, test set on a basis of past performance, etc. o The number of unplanned outages due to human error will increase considerably. o The requirement of a complete functional trip test will reduce the level of reliability and all levels of the BES to include distribution systems. o Availability of the BES will be reduced due to an increased need to schedule planned outages for test purposes (to avoid unplanned outages due to human error). o To implement this standard, an entity will need to hire additional skilled resources that are not readily available. (May require adjustments to the implementation timeline.) o The cost of implementing the revised standard will approximately double our existing cost to perform this work. 2. Requests that relevant reliability performance data (based on actual data and/or lessons learned from past operating incidents, Criteria for Approving Reliability Standards per FERC Order 672) be provided to justify the additional cost and reliability risks associated with functional testing. 3. Under a Performance-Based Program, what happens if the population of components drops below 60 (as all will eventually)? Is there an implementation period to default to TBM? 4. Please clarify In R1, the statement “or are designed to provide protection for the BES” re-opens the argument about transformer protection or breaker failure protection for transformer high-side breakers tripping BES breakers being included in the transmission protection systems. 5. Also, for Table 1b “Verify that each breaker trip coil, each auxiliary relay, and each lockout relay is electrically operated within this time interval” should be changed from a 6 year interval to a 12 year interval similar to the relay input and outputs. Experience has shown that these both have very

Organization	Question 7 Comment
	similar reliability. 6. The standard as currently drafted raises concern as it relates to the identification of all Protection System components, particularly those with associated communications equipment. In the case of leased lines, a utility would be expected to maintain equipment they do not own. Recommend revising the standard to consider maintenance activities on a communications channel basis in which intermediate device functioning can be verified by sending a signal from one relay to another. 7. Clarification should be given as to the reason for stating control circuitry separately, such as in “Control and trip circuits”. As currently stated, this implies that close circuit DC paths are now subject to a protection system maintenance program when reclosing and closing of breakers have never before been considered part of a Protection System. 8. Statements 3 (For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the Protection System.) and 6 (Verify correct operation of output actions that are used for tripping. in Table 1b for Protective Relays essentially address the same issue. Please clarify if these are addressing the same issue or not. If the purpose is to describe the functionality of the protection system, that should be covered under another section in the table, such as DC circuitry. 9. How one identifies a voltage and current sensing input is not well defined. In most cases, this should already be identified with the relay. Also, the scope of detail required is ambiguous. Would individual cables, terminal blocks, etc. need to be identified as would be implied by “associated circuitry”? Please clarify. The NSRS recommends that individual cables, terminal blocks, etc are not included in this program. 10. Recommend removing “proper functioning of” from the maintenance activities for voltage and current sensing inputs in Table 1b. A utility is not verifying the functionality of the signal(s), they are verifying the signals themselves. Any functioning of the signals, which is related to ensuring proper relay interpretation, would be covered under the protective relay section. 11. In general, has thought been put into the possibility of degrading reliability by implementing such a rigorous maintenance program? To implement such a program, the number of scheduled outages would greatly increase resulting in scheduling conflicts that will increase, as well as degrading

Organization	Question 7 Comment
	system conditions by taking lines, transformers, etc. out of service. Because of past design practices many of the requirements for maintenance will only be able to be performed by lifting wires to isolated trip paths. Potential error is introduced anytime a wire is lifted, especially numerous wires, by means of ensuring they are put back in the correct place. Redundancy is one thing that has been implemented in great detail throughout the history of protection systems to ensure that they work as intended. Diligent commissioning may need to be given its due credit.

Response: Thank you for your comments.

1. Thank you for your opinions.
2. The Standard does not preclude an entity from largely utilizing other methods of verification, although functional testing may be the easiest to achieve.
3. The entity must revert to TBM if the population falls below 60. There is no implementation period; the SDT believes that the annual PBM review will alert the entity that the population is nearing 60, and allow the entity to react to the diminishing component population accordingly.
4. This comment relates to your regional BES definition, not the Standard.
5. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-5. The SDT believes that mechanical solenoid-operated devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-based maintenance is an option to increase the intervals if the performance of these devices supports those intervals.
6. The functional testing of the channel will verify that the communications system operates properly. If the communications system does not perform properly, the applicable entity is responsible to assure that it is restored to service; the physical actions to do so may have to be performed by other parties. Your suggested end-to-end test is one effective way of performing this maintenance; however, this is only one of several ways of doing this.
7. This component of the definition is stated to apply as "associated with protective functions" and thus excludes close/reclosing circuits. Please see FAQ II.1.A.
8. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-1.
9. This component of the Protection System definition is to generally include this functionality as a part of the Protection System. The

Organization	Question 7 Comment
detailed applicability of this component within PRC-005-2 is addressed within the Standard. The "protective relay" only addresses how the relay itself uses these signals, but does not address the concern regarding whether these signals are accurate. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3. Requirement R1, part 1.1, has been revised to state, "Address all Protection System component types" to clarify that "individual cables, terminal blocks, etc." need not be discretely addressed. The definition has also been revised to remove "associated circuitry" from this portion. Please see FAQ II.3.A. 10. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-3. **11.** The SDT believes that performing these maintenance activities will benefit the reliability of the BES.	
Indiana Municipal Power Agency	1. The proposed effective date working is confusing and maybe incorrect. It looks like the second part of the paragraph refers to the additional maintenance and testing required by requirement 2 of the current version of PRC-005-1. PRC-005-2 will be adding additional maintenance and testing. Since the current wording is confusing, we are not sure when we have to ensure the new testing is done on the protection equipment. 2. When it comes to battery maintenance, the battery cell to cell connection resistance has to be verified. IMPA is not sure how the SDT wants this maintenance performed. Some battery banks are made up of individual battery cases with two posts at each end that contain two to four individual battery cells inside of each case. To actually tear down the individual cells in a case would be extremely hard and maybe impossible on the sealed cases without destroying the cases. It would be nice to describe how the SDT wants the connection resistance of battery cell to cell verified in the FAQ guide. 3. In the same guide, the SDT might give insight on what is meant by verifying the state of charge of the individual battery cell/units (table 1A). It seems like measuring the voltage level of the individual battery would work for this verification, but additional information of what the SDT wants for this verification would eliminate any doubt and help with being in compliant with this requirement.
Response: Thank you for your comments. 1. The SDT does not understand your concern. Perhaps you are referring to the Implementation Plan for the definition rather than the Implementation Plan for the Standard. The second bullet in the introductory portion of the Implementation Plan for the Standard has	

<table>
<tr><th>Organization</th><th>Question 7 Comment</th></tr>
<tr><td colspan="2">been modified to state, " ... is being performed according to …" rather than "has been moved to" to be more concise.
2. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. The term "cell" has been modified to "cell/unit" to address part of your concern. Please see FAQ II.5.L.
3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Table 1-4. IEEE Standards 1188, 450, and 1106 provide "how-to" guidance specific to various battery technologies.</td></tr>
<tr><td>ReliabilityFirst Corp.</td><td>The SDT should be congratulated on its hard work in making substantial improvements to an existing standard.
1. In revising the draft standard, the SDT should consider the difficulty an entity will have in providing the evidence required to show compliance.
2. R1 unnecessarily limits PSMPs to "Protection Systems that use measurements of voltage, current, frequency and or phase angle to determine anomalies." However, if an entity applies devices that protect equipment based on other non-electrical quantities or principles such as temperature or changes in pressure, the entity is not required to maintain them. These types of devices have long been considered by many organizations as important forms of protection and therefore in some instances are connected to trip. There are also many organizations that consider these types of devices too unreliable to use as protection and therefore only connect them for monitoring (and not to trip). If protection based on non-electrical quantities is not properly maintained, it will Misoperate and will negatively impact reliability. The standard cannot simply ignore a type of protection that can ultimately affect the reliability of the BES.</td></tr>
<tr><td colspan="2">Response: Thank you for your comments.
1. The SDT has considered this, and has provided examples in the Measures. Please see Section 15.7 of the Supplementary Reference document and FAQ IV.1.B.
2. Requirement R1 does not preclude entities from maintaining such devices or including them in the PSMP.</td></tr>
<tr><td>Indeck Energy Services</td><td>The standard should include an assessment of, and criteria for, determining whether a Protective System is important to reliability. It presently treats a fault current relay on a 345 kV or higher voltage</td></tr>
</table>

Organization	Question 7 Comment
	transformer the same as one on a small generator on the 115 kV system. The impact of failures on both on a hot summer day like we've had recently in NY, would be very different. As discussed at the FERC Technical Conference on Standards Development, the goal of the standards program is to avoid or prevent cascading outages--specifically not loss of load. This seems to have been lost in the drafting process. Much of the effort expended on complying with the existing PRC maintenance standards, as well as that to be expended on PRC-005-2, has little to no significant in terms of improving reliability. That effort could be better utilized if focused on activities that could significantly improve reliability. As one of the Commissioners at the FERC Technical Conference on Standards Development characterized the relationship between FERC and NERC as a wheel off the track. The whole standards program, and especially PRC-005-2, is off the track.
Response: Thank you for your comments. Your comments seem to be related to NERC Standards Development in general, and to BES definitions. The 2007-17 SDT is unable to address these concerns. The SDT is addressing its assignment from the approved SAR, and believes that performing maintenance on Protection Systems will benefit the reliability of the BES.	
US Bureau of Reclamation	1. The sub-requirements for R1, are not criteria, rather implementation requirements more suitable to be included in R4. Examples of what the PSMP shall address which would be more consistent with the language in R1 would be: • How are changes to the PSMP administered? • Who approves the determination of the use of time-based, condition based or performance based maintenance. • Who reviews activities under the PSMP 2. References used within the standard are not consistent. In R1.2 Attachment as is referred to as Attachment A. In R3 Attachment A is referred to as PRC-005 Attachment A. This implies a difference. Under a voluntary world, we could draft criteria and procedures with these problems and interpret them correctly. Today in the compliance world, the language must be precise and unambiguous. The reference must be the same it means something different. 3. The requirement in R1, which is consistent with the purpose, does not support the applicability in

Organization	Question 7 Comment
	R4.2.5.4. Protection systems associated with stations service are not designed to provide protection for the BES. In particular we have been told that intent was not to look at every device that tripped the generator but devises that sensed problems on the BES and trip the generator. Hence we include such things as frequency relays, Differential relays, zone relays, over current, and under voltage relays. Even a loss of field looks at the system as included. Speed sensing devices were explicitly excluded. As such, if the stations service transformer protection looks toward the BES (e.g. differential relays and zone relays) they would be included. Over current would not as it would be on the station side. If a Station Service transformer saw excess current, the system would in most cases fail over to other side. If not, it would cause the generator to trip much like a generator thermal device which is also excluded. Maintenance programs offer a unique problem to the FERC and regulatory world. The knee jerk reaction is to define them. What happens if the solution is bad, who will accept the consequences that narrow prescription was wrong and the interval caused a reliability impact. It would no longer be the Entity. History is replete with examples of this type of micro managing. Rather than fall into the same trap, and suffer the consequences of the unknown, allow Entities to optimize their programs to ensure reliability of the BES and create a standard of disallowed practices which have a demonstrated impact on reliability.
Response: Thank you for your comments. 1. Requirement R1 presents the requirements to establish a PSMP; Requirement R4 presents the implementation of the program. The SDT believes that this arrangement is correct. The examples cited seem to be related more to the internal administration of the PSMP within an entity, and not to the requirements. 2. The Standard has been modified to make these phrases consistent in consideration of your comment. 3. The SDT believes that the station service transformers may be essential to the operation of the generator (which is the BES element), and thus that the protection of these needs to be addressed as part of PRC-005-2.	
Bonneville Power Administration	1. The term “maintenance correctable issue” used in Requirement 4 seems to be at odds with the definition given for it. It seems that an issue that cannot be resolved by repair or calibration during the maintenance activity would be a maintenance non-correctable issue. Also, in Requirement 4, the term “identification of the resolution” is ambiguous. Suggested changes for Requirements 4 and 4.1

Organization	Question 7 Comment
	are: a. R4. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement its PSMP, and resolve any performance problems as follows: b. 4.3 Ensure either that the components are within acceptable parameters at the conclusion of the maintenance activities or initiate actions to replace the component or restore its performance to within acceptable parameters.
Response: Thank you for your comments. **1.** The definition of "maintenance correctable issue" is consistent with the way it is used within the Standard.	
Santee Cooper	There is some discussion in the documents, such as the definition of component in the Frequently-Asked Questions, about the idea that an entity has some latitude in determining the level of "protection system component" that they use to identify protection systems in their program and documentation. The example given is about DC control circuitry. There are requirements in this standard that are specific to a component, such as R1.1 - Identify all protection system components. Historically, if your maintenance and testing program is defined as (say, for relays) testing all the relays in a station at one time, your program, test dates, etc. could be identified by the station. There needs to be some addition, possibly to the Frequently asked questions, to explain what kind of documentation will be required with this new standard. For example, if your program is to test all the relays at a station every 4 years, and all the relays are tested at the same time, can your documentation of your schedule (the "date last tested" and previous date) be listed by station (accepting that you should have the backup data to show the testing was thorough) or must you be able to provide a list by each relay. Without some clarification, it seems like this could get confusing at an audit with many of the requirements pertaining to "each component."
Response: Thank you for your comments. Requirement R1, Part 1.1, has been revised to state, "Address all Protection System component types." The remaining issues within your comment are dependent on how your PSMP addresses them.	
Northeast Power	1. UFLS systems by design can suffer random failures to trip. A requirement should exist that stipulates to perform maintenance on the UFLS relay as their failure to operate may affect numerous

Organization	Question 7 Comment
Coordinating Council	distribution level feeders. However maintenance on associated DC schemes connected to the devices should only be done on the same frequency as maintenance on the relevant interrupting devices. Consideration should be given to exempting schemes that have a maintenance program in place on those distribution level devices from PRC-005 Standard-specified maintenance intervals. Such Standard-specified intervals could apply to interrupting devices that have no maintenance program in place. 2. This standard is overly prescriptive. Owners of protection system equipment establish maintenance procedures and timelines based on manufacturers' recommendations and experiences to ensure reliability. Maintenance intervals change with improved practices and equipment designs, and whenever that occurs PRC-005 will have to go through the revision process, which would be frequent and unnecessary if the standard were more general.
Response: Thank you for your comments. 1. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-1 through 1-5. 2. FERC Order 693 and the approved SAR for this project directed the SDT to establish both maximum maintenance intervals and minimum maintenance activities within the revised Standard.	
Entergy Services	We support this project and believe it is a positive step towards BES reliability. However, we believe the draft document needs additional work as per our comments. Also, as indicated by the amount of industry input on the last version draft comments, we believe revisions are still needed to properly address this technically complex standard. If this standard is to deviate from the original project schedule and follow a fast track timeline for approval, then we disagree with the 3 month implementation for Requirement 1 and ask for at least 12 months. The original schedule provided sufficient advance notice to work on an implementation plan and it included the typical time required for NERC Board of Trustees and regulatory approvals. If the project schedule and typical NERC Board of Trustees and regulatory approval times are to be accelerated, the implementation plan should be extended.
Response: Thank you for your comments. The Implementation Plan for Requirement R1 has been revised from 3 months to 12	

Organization	Question 7 Comment
months.	
Utility Services	With regard to DPs who own transmission Protection Systems, the standard is still very unclear on when a DP owns a transmission Protection System. Many DPs own equipment that is included within the definition of a Protection System; however, ownership of such equipment does not necessarily translate directly into a transmission Protection System under the compliance obligations of this standard. DPs need to know if this standard applies to them and right now, there is no certain way of determining that from within this language or previous versions of this standard. Additionally, the NPCC Regional Standards Committee withdrew a SAR on this very subject as we informed the question would be addressed in this proposal.
Response: Thank you for your comments. Your concern seems to be primarily related to the applicable regional BES definition.	
Y-W Electric Association, Inc.	1. Y-WEA concurs with Central Lincoln regarding the timing of required battery tests. The IEEE standards referenced indicate target maintenance intervals. In order to remain reasonable, then, this compliance standard needs to allow some buffer between a targeted maintenance and inspection interval and a maximum enforceable maintenance and inspection interval. Central Lincoln's suggestion of a four-month maximum window is reasonable and should be incorporated into the standard. 2. Y-WEA is also concerned with R1.1's language indicating that all components must be identified with no defined "floor" for the significance of a component to the Protection System. The SDT cannot possibly expect that a parts list containing every terminal block, wire and jumper, screw, and lug is going to be maintained with every single part having all the compliance data assigned to it, but without clearly stating this, that is exactly the degree of record-keeping that some overzealous auditor could attempt to hold the registered entity to. The FAQ is much clearer as to what is and is not a component and should be considered for the standard. 3. Y-WEA also concurs with FMPA's comments regarding the testing of batteries and DC control circuits associated with UFLS relaying. Many UFLS relays are installed on distribution equipment. Furthermore, many distribution equipment vendors are including UFLS functions in their distribution equipment. For example, many recloser controls incorporate a UFLS function in them. These

Organization	Question 7 Comment
	controls and the reclosers they are attached to, however, are strictly distribution equipment. 16 USC 824o (a)(1) limits the definition of the Bulk-Power System to "not include facilities used in the local distribution of electric energy." A distribution recloser and its control clearly fall into this exclusion. 16 USC 824o (i)(1) prohibits the ERO from developing standards that cover more than the Bulk-Power System. As such, the DC control circuitry and batteries associated with many UFLS relaying installations are precluded from regulation under NERC's reliability standards and may not be included in this standard because they are distribution equipment and therefore not part of the Bulk-Power System. The proposed standard needs to be rewritten to allow for this exclusion and to allow for the testing of only the UFLS function of any distribution class controls or relays.

Response: Thank you for your comments.

1. The SDT disagrees. You should complete the activities within the intervals specified.
2. Requirement R1, Part 1.1, has been revised to state, "Address all Protection System component types."
3. The Tables have been rearranged and considerably revised to improve clarity. Please see new Tables 1-4 and 1-5.

The new proposed definition of Protection System reads as follows:

Protection System:

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply, and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

Protection System Definition

Current Approved Definition:

Protective relays, associated communication systems, voltage and current sensing devices, station batteries and DC control circuitry.

The drafting team initially proposed changes to the definition as shown below:

Protective relays, associated communication systems necessary for correct operation of protective devices, voltage and current sensing inputs to protective relays ~~devices~~, station DC supply ~~batteries~~, and DC control circuitry from the station DC supply through the trip coil(s) of the circuit breakers or other interrupting devices.

Based on stakeholder comments, the drafting team made minor changes to the proposed definition as shown below.

Protective relays, ~~associated~~ communication systems necessary for correct operation of protective ~~devices~~functions, voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and ~~DC~~ control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers or other interrupting devices.

The proposed definition of Protection System reads as follows:

Protective relays which respond to electrical quantities, communication systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays ~~and associated circuitry from the voltage and current sensing devices~~, station dc supply, and control circuitry associated with protective functions ~~from the station dc supply~~ through the trip coil(s) of the circuit breakers or other interrupting devices.

The new proposed definition of Protection System reads as follows:

Protection System:

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply, and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

Implementation Plan for the Revised Definition of Protection System

Prerequisite Approvals or Activities:
The implementation of the revised definition is not dependent upon any other activity.

Recommended Modifications to Already Approved Standards
The non-capitalized version of the term, "protection system" is used in the following approved standards:

- NUC-001-2 — Nuclear Plant Interface Coordination
- PER-005-1 — System Personnel Training
- PRC-001-1 — System Protection Coordination

The term, "protection system" shall be capitalized where used in these standards when the definition of "Protection System" is approved by applicable regulatory authorities.

Proposed Effective Date:
Each responsible entity (Distribution Provider that owns a transmission Protection System, Transmission Owner, and Generator Owner) shall modify its protection system maintenance and testing program description and basis document(s) (required in Requirement R1 of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing) as necessary to reflect the modified definition of 'Protection System' by the first day of the first calendar quarter twelve months following regulatory approvals and implement any additional maintenance and testing (required in Requirement R2 of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing) by the end of the first complete maintenance and testing cycle described in the entity's program description and basis document(s) following establishment of the program changes resulting from the revised definition.

The original definition of "Protection System" shall be retired at the same time the revised definition becomes effective.

NERC
NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Implementation Plan for the Revised Definition of Protection System

Prerequisite Approvals or Activities:

The implementation of the revised definition is not dependent upon any other activity.

Recommended Modifications to Already Approved Standards

The non-capitalized version of the term, "protection system" is used in the following approved standards:

- NUC-001-2 – Nuclear Plant Interface Coordination
- PER-005-1 – System Personnel Training
- PRC-001-1 – System Protection Coordination

The term, "protection system" shall be capitalized where used in these standards when the definition of "Protection System" is approved by applicable regulatory authorities.

Proposed Effective Date:

Each responsible entity (Distribution Provider that owns a transmission Protection System, Transmission Owner, and Generator Owner) shall modify its protection system maintenance and testing program description and basis document(s) (required in Requirement R1 of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing) as necessary to reflect the modified definition of 'Protection System' by the ~~end~~ first day of the first calendar quarter ~~six~~ twelve months following regulatory approvals and implement any additional maintenance and testing (required in Requirement R2 of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing) by the end of the first complete maintenance and testing cycle described in the entity's program description and basis document(s) following establishment of the program changes resulting from the revised definition.

The original definition of "Protection System" shall be retired at the same time the revised definition becomes effective.

Standards Announcement

Second Ballot Window Open
July 23–August 2, 2010

Now available at: https://standards.nerc.net/CurrentBallots.aspx

Project 2007-17: Protection System Maintenance and Testing
A second ballot window for the definition of “Protection System” is now open **until 8 p.m. Eastern on August 2, 2010**.

Instructions
Members of the ballot pool associated with this project may log in and submit their votes from the following page: https://standards.nerc.net/CurrentBallots.aspx

Recirculation Ballot Process
The Standards Committee encourages all members of the ballot pool to review the consideration of comments submitted with the initial ballots and those submitted through the formal comment period. In this second ballot, votes are counted by exception only — if a ballot pool member does not submit a revision to that member’s original vote, the vote remains the same as in the first ballot. Members of the ballot pool may:

- Reconsider and change their vote from the first ballot.
- Vote in the second ballot even if they did not vote on the first ballot.
- Take no action if they do not want to change their original vote.

Next Steps
Voting results will be posted and announced after the ballot window closes.

Project Background
When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the Protection System and Maintenance Standard Drafting Team, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given “priority.” The Standards Committee directed the team to advance the definition of Protection System in parallel with the development of PRC-005-2.

Special Notes:
On March 18, 2010, FERC issued several orders and notices of proposed rulemakings pertaining to standards development activities and processes, suggesting a lack of progress in responding to directives from Order 693 as well in the timeliness of standards development in general. At the May 2010 NERC Board meeting, Gerry Cauley, NERC's President, also expressed these concerns, indicating that the resolution to these concerns is one of NERC's top priorities in the near term. As a result, the Standards Committee has authorized deviations from the normal standards development process for the Protection System Maintenance and Testing project, as well as other projects, to demonstrate that the NERC enterprise is responsive to FERC directives, and is making progress in developing standards.

The Standards Committee approved the following deviations from the standards development process for the definition of Protection System:

- The proposed changes to the definition will be posted for a 35-day comment period (rather than 45-day comment period). The ballot pool will be formed during the first 21 days of the 35-day comment period;
- The initial ballot will be conducted during the last 10 days of the 35-day comment period; and
- The drafting team may make modifications between the initial and successive ballots based on stakeholder comments to improve the overall quality of the standard and definition.

Standards Development Process

The Reliability Standards Development Procedure contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance, please contact Lauren Koller at Lauren.Koller@nerc.net

RELIABILITY CORPORATION

Standards Announcement
Final Ballot Results

Now available at: https://standards.nerc.net/Ballots.aspx

Project 2007-17: Protection System Maintenance and Testing
The second ballot for the definition of "Protection System" ended on August 2, 2010.

Ballot Results
Voting statistics are listed below, and the Ballot Results Web page provides a link to the detailed results:

Quorum: 94.70%
Approval: 58.61%

Next Steps
The drafting team will review and respond to the comments received, and will determine whether to make additional changes to the definition or its implementation plan, based on those comments. Should the team decide to make revisions the revised item(s) will be posted for a 30-day comment period with another ballot conducted during the last ten days of that comment period.

Project Background
When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the Protection System and Maintenance Standard Drafting Team, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." The Standards Committee directed the team to advance the definition of Protection System in parallel with the development of PRC-005-2.

More information is available on the project page:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.htmlb

Standards Development Process
For this project, the Standards Committee authorized using the standard development process in the *Standard Processes Manual*. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

Ballot Criteria (from *Standard Processes Manual*)
Approval requires both a (1) quorum, which is established by at least 75% of the members of the ballot pool for submitting either an affirmative vote, a negative vote, or an abstention, and (2) A two-thirds majority of the weighted segment votes cast must be affirmative; the number of votes cast is the sum of affirmative and negative votes, excluding abstentions and nonresponses. If there are no negative votes with reasons from the first ballot, the results of the first ballot shall stand. If, however, one or more members submit negative votes with reasons, at least one more ballot must be conducted. If the drafting team makes no substantive changes following the initial ballot, then a "recirculation" ballot is conducted – however if the drafting team makes substantive changes, the revised standard (or definition) must be posted for a 30-day comment period, with a successive ballot conducted during the last 10 days of that comment period. If the drafting team does not make substantive changes following the successive ballot, then the standard moves forward to a recirculation ballot.

For more information or assistance, please contact Courtney Camburn at Courtney.camburn@nerc.net

Consideration of Comments on Second Ballot — Project 2007-17 Protection System Maintenance (Protection System definition)

Date of Second Ballot: 07/23/10 - 08/02/10

Summary Consideration: There were numerous comments opposing balloting the definition separately from the definition; the NERC BOT has directed that a revised definition be approved as quickly as possible to close a reliability gap. Many other comments were offered relative to the standard, not the definition, and the SDT noted this in its responses.

Some commenters suggested the "station dc supply" portion of the definition be modified to specifically address battery chargers; the SDT modified the definition as suggested. The revised definition is shown below:

Protection System –

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The SDT did not make any other modifications to the definition and did not make any modifications to the implementation plan based on stakeholder comments submitted with ballots.

If you feel that the drafting team overlooked your comments, please let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 609-452-8060 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedure: http://www.nerc.com/files/RSDP_V6_1_12Mar07.pdf.

Voter	Entity	Segment	Vote	Comment
Kirit S. Shah	Ameren Services	1	Negative	1. Remove “devices providing” yielding ‘voltage and current sensing inputs to protective relays’. This will match the SDT intent with which we concur. "The definition has been changed for clarity; the SDT intends that the output of these devices, measured at the relay should properly represent the primary quantities." 2. The 12 month implementation plan is an improvement, but will result in multiple maintenance plan changes within a short time. We believe that the implementation of the revised definition and PRC-005-2 PSMP must align on the same date.
Response: Thank you for your comments. 1. The definition of Protection System is for all applications of this term throughout NERC Standards. The detailed applicability of this element of the definition relative to maintenance within PRC-005-2 is addressed within the standard by specifying, “Verify that acceptable measurements of the current and voltage signals are received by the protective relays”. 2. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.				
Terri F Benoit	Entergy Services, Inc.	6	Negative	2007-17 the definition - Negative with Comments: The following are the reasons associated with our Negative Ballot. 1. We agree with the definition, however we do not agree with the implementation plan. We believe implementation of the definition needs to coincide with the implementation of Standard PRC-005-2. To do otherwise, will cause entities to address equipment, documentation, work management process, and employee training changes needed for compliance twice within an unreasonably short timeframe. 2. A 12 month minimum timeframe is need to implement this definition
Response: Thank you for your comments.				

Voter	Entity	Segment	Vote	Comment
1. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1. 2. The SDT modified the implementation plan to provide a 12-month implementation period with the previous posting.				
Brenda L Truhe	PPL Electric Utilities Corp.	1	Affirmative	Although PPL EU previously voted against this definition, due to the change in language, we now support this definition.
Response: Thank you for your comments.				
John C. Collins	Platte River Power Authority	1	Negative	Although the applicable relays to which protective relays are outlined in the NERC PRC-005-2 Protection system Maintenance Draft Supplementary Reference dated May 27, 2010, they are not defined in the NERC Glossary of terms. Until it is clearly defined which relays are included inconsistencies will exists from region to region in their audit approaches and which relays they will be looking at. Also, there is still debate why the protective relays would extend to mechanical devices such as the lock-out relay and tripping for trip-free relays. In our system configuration we risk reliability to customer load by testing the lock-out relays which we feel out weights the benefit of testing devices that we see little to no evidence of failure in.
Terry L Baker	Platte River Power Authority	3	Negative	
Response: Thank you for your comments. The definition of Protection System is for all applications of this term throughout NERC Standards. The detailed applicability of the definition relative to maintenance within PRC-005-2 is addressed within the standard. Your comments appear to be on the draft standard PRC-005-2, rather than on the definition. Failure of a lock-out relay or tripping relay can keep a circuit (or multiple circuits) from clearing a fault. Routine testing of these devices could find problems before the system needs them to clear a fault.				
Mel Jensen	APS	5	Negative	Although the SDT has made changes in trying to define the Protection System the definition remains too prescriptive. In particular, the devices providing current and voltage inputs as well as the dc supply. These items are also used for other functions not related to the reliability of the BES. They are critical to business and operation of the generating systems and not solely dedicated to protective relaying. Including them in the definition obligates the utility to methods where there should be some discretion.
Robert D Smith	Arizona Public Service Co.	1	Negative	

Voter	Entity	Segment	Vote	Comment
Response: Thank you for your comments. The SDT is aware that many devices have multiple functions within the business of supplying power to loads. Regardless of these other functions, if a device is a part of a Protection System then it must be maintained in accordance withPRC-005. The definition of Protection System is for all applications of this term throughout NERC Standards. The detailed applicability of the definition relative to maintenance within PRC-005-2 is addressed within the standard.				
Stan T. Rzad	Keys Energy Services	1	Negative	As written, is opens up the PRC-005 standard to Technical Feasibility Exceptions because some batteries are not able to accommodate all of the tests proscribed in the draft standard. The draft standard would cause NERC to regulate through the standards battery testing, DC circuit testing, etc. on distribution elements with no significant improvement to BES reliability, which is beyond the statutory scope of the standards The standard unreasonably retains the "100% compliance" paradigm for thousands, if not millions of protection system components.
Response: Thank you for your comments. Your comments appear to be relative to the draft standard PRC-005-2, rather than the definition. The SDT had not completed the consideration of comments on the standard when the definition was re-posted. The SDT has responded to similar comments within the responses to ballot comments and the consideration of comments on the standard itself.				
Joseph S. Stonecipher	Beaches Energy Services	1	Negative	Because the definition changes the scope of what PRC-005 covers, the definition should not be balloted separately from PRC-005 so that the industry knows what is being committed to. What happens if the standard is voted down but the definition change is passed? For instance, the circuitry connecting the voltage and current sensing devices to the relays is a scope expansion. Station DC supply increases the scope to include the charger, etc. This scope increase needs to have an appropriate implementation period.
Thomas W. Richards	Fort Pierce Utilities Authority	4	Negative	
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.				
Paul Rocha	CenterPoint Energy	1	Negative	CenterPoint Energy does not support any Protection System definition that includes the trip coils of the interrupting devices.
Response: Thank you for your comments. The current definition includes “DC Control Circuitry”; the SDT attempted to clarify the definition by stating which				

<table>
<tr><th>Voter</th><th>Entity</th><th>Segment</th><th>Vote</th><th>Comment</th></tr>
<tr><td colspan="5">of the many control circuits are included. Because the current definition is vague, it can certainly include the trip coils, close coils, and alarm circuits of the interrupting device. The SDT believes that the electrically-operated trip coils are an important part of the control circuitry.</td></tr>
<tr><td>Christopher L de Graffenried</td><td>Consolidated Edison Co. of New York</td><td>1</td><td>Negative</td><td rowspan="2">Comment: There is not enough clarity on whether a Distribution Provider (DP) will be able to clearly identify which protection system components it does own and needs to maintain. Many DPs own and/or operate equipment identified in the existing or proposed definition. However, not all such equipment translates into a transmission Protection System. The definition needs clarification on when such equipment is a part of the transmission protection system. Also, the time provided for the first phase "at least six months" is too open ended and does not provide entities with a clear timeline. It is suggested that one year is appropriate for the first phase phasing out the second year in stages.</td></tr>
<tr><td>Nickesha P Carrol</td><td>Consolidated Edison Co. of New York</td><td>6</td><td>Negative</td></tr>
<tr><td colspan="5">Response: Thank you for your comments. Your comments appear to be relative to the draft standard PRC-005-2, rather than the definition. The SDT had not completed consideration of comments on the standard when the definition was re-posted. The SDT has responded to similar comments within the responses to ballot comments and the consideration of comments on the standard itself.

Regarding the comment that the definition needs to identify when equipment is part of the transmission system, this is properly an issue to address in the various standards that use this definition.</td></tr>
<tr><td>Hugh A. Owen</td><td>Public Utility District No. 1 of Chelan County</td><td>6</td><td>Negative</td><td>Comments have convinced me that ambiguities in the requirements will make compliance/enforcement difficult and the testing procedures may not lead to greater reliability.</td></tr>
<tr><td colspan="5">Response: Thank you for your comments. Your comments appear to be relative to the draft standard PRC-005-2, rather than the definition. The SDT had not completed the consideration of comments on the standard when the definition was re-posted. The SDT has responded to similar comments within the responses to ballot comments and the consideration of comments on the standard itself.</td></tr>
<tr><td>Charles A. Freibert</td><td>Louisville Gas and Electric Co.</td><td>3</td><td>Affirmative</td><td>Comments will be submitte4d under the comment form</td></tr>
<tr><td colspan="5">Response: Thank you for your comments. There was no formal comment period with the second ballot of the proposed definition.</td></tr>
</table>

Voter	Entity	Segment	Vote	Comment
Ralph Frederick Meyer	Empire District Electric Co.	1	Negative	Comments: It is still unclear whether relays that respond to mechanical inputs, such as sudden pressure relays, are included in the proposed definition as protective relays. While PRC-005-2 R1 limits the scope of that particular standard to protection systems that sense electrical quantities, it is remains unclear in other standards that use the defined term whether mechanical input protections are included. We suggest that "Protective Relay" also be defined, and that the definition clearly exclude devices that respond to mechanical inputs in line with the NERC interpretation of PRC-005-1 in response to the CMPWG request.
Response: Thank you for your comments. The definition has been modified to include only protective relays that respond to electrical quantities. The SDT sees no need to either repeat or modify the IEEE definition of protective relays.				
Michael J. Haynes	Seattle City Light	5	Negative	Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices. - In order to comply with this statement utilities would need to conduct functional tests of their relay system. This type of test is problematic. A better definition would be to test the output of the relay.
Response: Thank you for your comments. This component of the Protection System definition is to generally include this functionality as a part of the Protection System for all applications of the definition throughout NERC Standards. The detailed applicability of this component relative to maintenance within PRC-005-2 is addressed within the standard, which defines the maintenance required relative to control circuits. The SDT agrees that testing will be required in the standard itself.				
Jim D. Cyrulewski	JDRJC Associates	8	Negative	1. Definition needs to be more specific. Case in point if the drafting team wants to include battery chargers should state so. 2. Also implementation plan does not appear to be in synch with proposed changes.
Response: Thank you for your comments. 1. The current definition uses the term batteries in place of dc supply. The use of the term batteries was quite specific and as such excluded battery chargers. The definition has been modified to specifically include battery chargers. Battery chargers are now expected to be covered within the proposed definition and the term dc supply, so too are systems that do not use batteries and/or battery chargers. 2. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given				

Voter	Entity	Segment	Vote	Comment
"priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.				
Daniel Brotzman	Commonwealth Edison Co.	1	Affirmative	Exelon suggests that the definition further clarify protective relays that are in scope by adding the following to the frequently asked questions: 1. "devices providing inputs to protective relays" - this is to clarify that testing for CTs and PTs will only ensure proper voltage and current into the relay - therefore not requiring CT and PT testing. 2. Elimination of "from the station dc supply" - the intent here is that the DC is testing only the trip functionality to ensure that certain relays actuate (e.g., 86 and 94 devices) and to ensure that breaker trip coils are exercised on a 6 year periodicity. Therefore, the ancillary wiring part of the controls will be on a longer periodicity (e.g., 12 years)
Response: Thank you for your comments. Your comments appear to be relative to the FAQs for PRC-005-2, rather than the definition. The SDT will consider these comments when it updates the FAQs.				
Robert Martinko	FirstEnergy Energy Delivery	1	Affirmative	FirstEnergy appreciates the hard work of the drafting team, but ask that the team consider the following suggestions: It is our understanding that the phrase "Station DC supply" in the definition is intended to cover the Battery, Battery Charger, and other DC supplies sources such as flywheels, fuel cells, and motor-generator sets. However, since the current Protection System Maintenance and Testing standard PRC-005-1 does not specify maintenance activities, as does the proposed Version 2 of PRC-005, it therefore does not provide compliance certainty related to mandatory expectations. This is because the current standard only requires that an entity develop a maintenance program and follows their program. Therefore, it is not clear from the definition that Battery Chargers must be included in the maintenance program developed per PRC-005-1. As we stated in our Initial Ballot comments, the phrase "Station DC supply" should be clarified. In response to our Initial Ballot comments the SDT stated "Clarifications such as this properly belong in supplementary materials. This is described in the FAQ posted in June 2010 (FAQ II.5.A)". We do not agree that supplementary materials should be relied upon to determine
Kevin Querry	FirstEnergy Solutions	3	Affirmative	
Kenneth Dresner	FirstEnergy Solutions	5	Affirmative	
Mark S Travaglianti	FirstEnergy Solutions	6	Affirmative	
Douglas Hohlbaugh	Ohio Edison Company	4	Affirmative	

Voter	Entity	Segment	Vote	Comment
				"what" is required and should only give you guidance on "how" to comply. The "what" should be described in the standard requirements and definitions.
Response: Thank you for your comments. It is the intent of the SDT that battery chargers and other devices that supply power to Protection System devices be included within the definition. As such, those devices have been included within the minimum maintenance activities of PRC-005-2. However, in the interim before PRC-005-2 is accepted, under the present PRC-005-1 an entity must have a maintenance program that includes the devices within the definition. PRC-005-1 does not prescribe the maintenance, only that the PSMP must include maintenance for the device. The definition has been modified to specifically include battery chargers.				
Pawel Krupa	Seattle City Light	1	Negative	Functional testing is impractical.
Dana Wheelock	Seattle City Light	3	Negative	
Hao Li	Seattle City Light	4	Negative	
Response: Thank you for your comments. The definition of Protection System is for all applications of this term throughout NERC Standards. The detailed applicability of this element relative to maintenance within PRC-005-2 is addressed within the standard, which defines the maintenance required relative to control circuits. Your comments appear to be relative to the draft standard PRC-005-2, rather than the definition. The SDT had not completed the consideration of comments on the standard when the definition was re-posted. The SDT has responded to similar comments within the responses to ballot comments and the consideration of comments on the standard itself. The SDT agrees that testing will be required in the standard itself.				
Dennis Sismaet	Seattle City Light	6	Negative	Functional testing is impractical. Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices. - " In order to comply with this statement utilities would need to functional test their relay system. A better definition would be to test the output of the relay"
Response: Thank you for your comments. The definition of Protection System is for all applications of this term throughout NERC Standards. The detailed applicability of this element relative to maintenance within PRC-005-2 is addressed within the standard, which defines the maintenance required relative to control circuits. Your comments appear to be relative to the draft standard PRC-005-2, rather than the definition. The SDT had not completed the consideration of comments on the standard when the definition was re-posted. The SDT agrees that testing will be required in the standard itself.				
Mark Ringhausen	Old Dominion Electric Coop.	4	Affirmative	I am voting Yes on the ballot, but I do have a small issue with the wording of 'station DC supply'. In some of our UFLS locations, we are not in a substation, but out on the feeder circuit and utilizing the DC supply on the feeder recloser. I think my reading of this definition would apply to this recloser DC supply as well as the

Voter	Entity	Segment	Vote	Comment
				Station DC Supply.
Response: Thank you for your comments. Your concern is appreciated. A review of the standard itself shows that the dc supply maintenance activities are minimal related to UFLS.				
Jeff Mead	City of Grand Island	5	Negative	I echo MRO NSRS comments.
Response: Thank you for your comments. The station dc supply element has been modified essentially as you suggest. As to your suggestion regarding inclusion of "BES' within the definition – this is properly an issue to address in the various standards that use this definition.				
John Yale	Chelan County Public Utility District #1	5	Negative	If the new definition is: The new proposed definition of Protection System reads as follows: Protection System: o Protective relays which respond to electrical quantities, o Communications systems necessary for correct operation of protective functions, o Voltage and current sensing devices providing inputs to protective relays, o Station dc supply, and o Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices. In this list format, it appears it is the entire station dc supply not just that portion and circuitry associated with the protective circuits. This is an unreasonable burden as many parts of the station dc supply are used for non-protective functions.
Response: Thank you for your comments. The SDT has modified the definition in consideration of your comments. That bullet now reads: station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply)				
Joseph O'Brien	Northern Indiana Public Service Co.	6	Negative	1. It is still not clear whether battery chargers fall under this definition. 2. The implementation plan should be coordinated with the new PRC-005-2, not -1. 3. It's not clear if a breaker trip has to be actuated to test/maintain the control circuitry through the trip coils.

Voter	Entity	Segment	Vote	Comment
				and testing program of R1 has not been reached yet, or are two maintenance and tests needed to be auditably compliant?
Response: Thank you for your comments. The SDT observes that the implementation plan for the definition requires that the entity implement the revised program. The implementation plan also requires completion of maintenance within one full cycle of the revised program.				
Martin Bauer P.E.	U.S. Bureau of Reclamation	5	Negative	1. It is unfortunate that the definition did not retain consistency in the terms. As an example, the definition indicates it includes protective relays and communication systems for the correct operation of protective functions. It would have been better to use the term relays instead of the term functions. 2. Now it is unclear what the communication systems are for, since a different term was used rather than protective relays. Since it is not clear what the communications have to do with protective relays, as it may also include those that do not just respond to electrical quantities, the definition cannot be used to support the standard. 3. The change to insert the term "devices providing" when referring to voltage and current sensing unfortunately eliminates the circuitry form the voltage and current sensing devices to the relays. This was caused by inserting the word “devices”. I do not believe it was the SDT intent, however, we are in a literal word world. Since we are primarily focused on the performance of the device as a function of the burden on the device, I cannot vote in favor. My company believes the circuit from the PT and CT must be a part of the Protection System and is arguably of greater concern. Consider that if a PT or CT fails partially or completely it will be known immediately. Maintenance practices will rarely help that predict failure. On the other hand, the circuitry from the voltage and current sensing devices can have a problem that will affect relay performance through instrument transformer error and in most cases is only found through testing. Had you changed “devices” to “circuits” I would agree with providing the first issue addressed as well. The term

Voter	Entity	Segment	Vote	Comment
				"circuits" could have included both (devices and circuits), but as I explained, the latter is more important, more variable, and has been attributed to many protection system failures.

Response: Thank you for your comments.

1. "Protective relays which respond to electrical quantities" is a description intended to clarify which relays are excluded (those not responding to electrical quantities are excluded). However a different descriptor was aimed at communications devices; after all there are many communication circuits employed that are not used for protective functions (voice, alarm data, revenue data, etc.).
2. The term "communications systems necessary for correct operation of protective functions" was chosen to include all methods of conveying tripping, permissive and blocking signals that are used now or may be used in the future. The SDT saw no need to include language that might result in the inclusion of voice equipment.
3. The change to insert the term "devices providing" was to improve clarity while also excluding voltage and current measuring devices that provide data exclusively to metering equipment as opposed to Protection Systems. The SDT agrees with the commenter that an appropriate maintenance activity is to ensure that the measured voltage and current values correctly make it to the relays. The maintenance activity is a part of the standard. The absence of this activity from the definition is not intended to lead one to believe that the activity is not important.

Voter	Entity	Segment	Vote	Comment
John J. Moraski	Baltimore Gas & Electric Company	1	Negative	It seems not to be the intention of the SDT to require testing of CT's and PT's beyond verifying that they that are delivering acceptable signals to relays. Table 1 a of the standard includes: - Voltage & Current Sensing Devices / 12 Calendar Years / Verify proper functioning of the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays. The FAQ's are even clearer and say: *********************************** 3. Voltage and Current Sensing Device Inputs to Protective Relays A. What is meant by "...verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays ..." Do we need to perform ratio, polarity and saturation tests every few

Voter	Entity	Segment	Vote	Comment
Amir Y Hammad	Constellation Power Source Generation, Inc.	5	Negative	years? No. You must prove that the protective relay is receiving the expected values from the voltage and current sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. Some examples follow: - Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit. - Compare the values, as determined by the questioned relay, to another protective relay monitoring the same line, with currents supplied by different CTs. - Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay. - Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay. The point of the verification procedure is to ensure that all of the individual components are functioning properly; and that, an ongoing proactive procedure is in place to re-check the various components of the protective relay measuring systems. ********************************** But the neither the originally revised or newly revised definitions carry that implication very well. Suppose the phrase in the definition were changed from: “Voltage and current sensing devices providing inputs to protective relays” to; “Voltage and current sensing device output circuits and the associated circuits to the inputs of protective relays”. This would make the whole definition read: Protection System: Protective relays which respond to electrical quantities, communication systems necessary for correct operation of protective functions, voltage and current sensing device output circuits and the associated circuits to the inputs of protective relays, station dc supply, and control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

Response: Thank you for your comments. Your comments appear to be relative to the draft standard PRC-005-2, rather than the definition. The SDT had not completed the consideration of comments on the standard when the definition was re-posted. The SDT has responded to similar comments within the

Voter	Entity	Segment	Vote	Comment
responses to ballot comments and the consideration of comments on the standard itself. You have put together a complete discussion of the fact that there is more to a system than merely 5 listed devices.				
Garry Baker	JEA	3	Negative	JEA believes the change in the definition should coordinate with the new standard PRC-005-002.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.				
William Mitchell Chamberlain	California Energy Commission	9	Negative	Lack of clarity or apparent conflict between certain requirements would make compliance assessment difficult.
Response: Thank you for your comments. Your comments appear to be relative to the draft standard PRC-005-2, rather than the definition. The SDT had not completed the consideration of comments on the standard when the definition was re-posted. The SDT has responded to similar comments within the responses to ballot comments and the consideration of comments on the standard itself.				
Bruce Merrill	Lincoln Electric System	3	Negative	LES would like to thank the Drafting Team for its time and effort in developing the definition. However, at this time LES believes that the implementation plan for the definition should be directly linked to the approval and implementation schedule for PRC-005-2 and the proposed definition of Protection System is incomplete as written and remains open to interpretation. LES offers the following Protection System definition for the SDT's consideration: "Protection System" is defined as: A system that uses measurements of voltage, current, frequency and/or phase angle to determine anomalies and trips a portion of the BES and consists of 1) Protective relays, and associated auxiliary relays, that initiate trip signals to trip coils, 2) associated communications channels, 3) current and voltage transformers supplying protective relay inputs, 4) dc station supply, excluding battery chargers, and 5) dc control trip path circuitry to the trip coils of BES connected breakers, or equivalent interrupting device, and lockout relays.
Dennis Florom	Lincoln Electric System	5	Negative	
Eric Ruskamp	Lincoln Electric System	6	Negative	
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close				

Voter	Entity	Segment	Vote	Comment
this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1. The SDT disagrees with several aspects of your suggested changes: Auxiliary relays are not a protective relay, but are instead a part of the dc control circuit; “associated” communication systems is too vague to address existing concerns with the definition; battery chargers specifically should NOT be excluded; and “to the trip coils” does not include trip coils as intended by the SDT. The SDT has made changes to the definition which may address other parts of your comment				
Robert Ganley	Long Island Power Authority	1	Affirmative	LIPA offers the following definition which we feel is clearer: Protective relays which respond to electrical quantities, communication systems required for operation of protective functions, voltage and current sensing devices to protective relays, station dc supply, and control circuitry from the associated protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.
Response: Thank you for your comments. The SDT has adopted your suggestion regarding Protective Relays.				
Saurabh Saksena	National Grid	1	Affirmative	National Grid suggests adding “Protection System Components including” in the beginning. This is because the word “components” has been used extensively throughout the standard and there is no mention of what constitutes a protection system component in the standard. The word “component” does find mention in FAQs, however, it is recommended to mention it in the main standard. Also, National Grid proposes a change in the proposed definition (changing "voltage and current sensing inputs" to "voltage and current sensing devices providing inputs"). The revised definition should read as follows: Protective System Components including Protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers or other interrupting devices. The time provided for the first phase “at least six months” is too open ended and does not give entities a clear timeline. National Grid

Voter	Entity	Segment	Vote	Comment
				suggests 1 year for the first phase. As a result, National Grid suggests phasing out the second phase in stages.
Response: Thank you for your comments. The SDT believes that inclusion of the defined term within its own definition is not appropriate, and declines to adopt your suggestion regarding the definition. The Implementation Plan and definition have both been modified in a manner that supports your comments.				
Liam Noailles	Xcel Energy, Inc.	5	Negative	NERC has indicated that this definition is being processed to close a reliability gap. It is not clear as to what gap this proposed definition is closing. The use of the term “Station DC Supply” actually introduces more confusion since some entities may view this as only batteries, and not include chargers. It would appear that the intent is to ensure that during a loss of substation service power scenario that the source of power (whatever that may be) to the Protection System is available and able to perform as designed. Recommend the definition be re-written to make it clear as to what components related to this assured source of power are required to be maintained as part of the Protection System, or alternatively define “Station DC Supply”.
David F. Lemmons	Xcel Energy, Inc.	6	Negative	
Response: Thank you for your comments. The definition has been modified to specifically include battery chargers.				
David H. Boguslawski	Northeast Utilities	1	Negative	NU believes that a protection system includes: 1) Protective relays which respond to electrical quantities, 2) Communications systems necessary for correct operation of protective functions, 3) Voltage and current sensing devices providing inputs to protective relays", and associated circuitry from the voltage and current sensing devices" 4) Station dc supply, and 5) Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices The proposed definition excludes "and associated circuitry from the voltage and current sensing devices" from item 3. NU believes that the associated circuitry for voltage and current sensing devices should be included. It is our concern that the proposed definition implies PRC-005 will apply specifically to the voltage and current sensing devices and not include the AC circuitry between these devices and the relay inputs.
Response: Thank you for your comments. The words of the definition were chosen to help clarify and exclude devices used exclusively for non-protective functions (metering, etc.), while the maintenance standard itself has a minimum maintenance activity that seeks to demonstrate the importance of the entire				

Voter	Entity	Segment	Vote	Comment
scheme.				
Chifong L. Thomas	Pacific Gas and Electric Company	1	Affirmative	PG&E believes the definition should identify that the protection system is associated with direct BES electrical quantities with the intention of protecting the BES from any device from propagating a problem in one part of the BES to another. The definition should not include associated systems, i.e. auxiliary systems including their transformers, motors, etc. For generating stations the protection included should only be the generator itself and its associated main bank transformer that delivers the power to the system. Likewise, for distribution substations, the protection should only include equipment such as the main transformer that draws power from the BES and not equipment such as distribution feeders.
Response: Thank you for your comments.				
James D. Hebson	PSEG Energy Resources & Trade LLC	6	Affirmative	Please reference comments submitted by the PSEG companies on the official comment form for this standard.
Response: Thank you for your comments. For this second ballot, there was no formal comment period.				
Rebecca Berdahl	Bonneville Power Administration	3	Negative	Please see BPA's comments submitted during the concurrent formal comment period ending July 16, 2010.
Response: Thank you for your comments. The SDT changed the definition following the formal comment period that ended July 16, 2010.				
Mark A Heimbach	PPL Generation LLC	5	Negative	Please see comments submitted by "PPL Supply" on 7/16/10.
Response: Thank you for your comments. The SDT changed the definition following the formal comment period that ended July 16, 2010.				
Laurie Williams	Public Service Company of New Mexico	1	Negative	PNM rejects this definition as too broad and not consistent with the way utilities treat the various items in the definition, but agrees with the proposed changes to the implementation plan.
Response: Thank you for your comments. Absent specific comments on the definition, the SDT is unable to respond to your concerns.				

Voter	Entity	Segment	Vote	Comment
Wayne Lewis	Progress Energy Carolinas	5	Affirmative	Progress Energy does not believe that the definition should be implemented separately from and prior to the implementation of PRC-005-2. We believe there should be a direct linkage between the definition's effective date to the approval and implementation schedule of PRC-005-2. Since this new definition should be directly linked to the proposed revised standard, it would be premature to make this new definition effective prior to the effective date of the new standard. We believe that changes to the maintenance program should be driven by the revision of the PRC standard, not by the revision of a definition.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.				
Kenneth D. Brown	Public Service Electric and Gas Co.	1	Affirmative	PSE&G is now voting affirmative. Thanks to the drafting team for improving the clarity of the definition.
Response: Thank you for your comments.				
Dan R. Schoenecker	Midwest Reliability Organization	10	Negative	Revise Protection System definition to: o BES Protective relays which respond to electrical quantities, o Communications systems necessary for correct operation of the BES protective functions, o Voltage and current sensing devices providing inputs to BES protective relays, o Battery and battery chargers that supply dc to BES protective relays, communications, and control circuitry, and o Control circuitry associated with the BES protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.
Response: Thank you for your comments. The station dc supply component type has been modified essentially as you suggest. As to your suggestion regarding inclusion of "BES' within the definition – this is properly an issue to address in the various standards that use this definition.				

Voter	Entity	Segment	Vote	Comment
Thomas C. Mielnik	MidAmerican Energy Co.	3	Negative	Revise Protection System definition to: BES Protective relays which respond to electrical quantities, Communications systems necessary for correct operation of the BES protective functions, Voltage and current sensing devices providing inputs to BES protective relays, Battery and battery chargers that supply dc to BES protective relays, communications, and control circuitry, and Control circuitry associated with the BES protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.
Response: Thank you for your comments. The station dc supply component type has been modified essentially as you suggest. As to your suggestion regarding inclusion of “BES’ within the definition – this is properly an issue to address in the various standards that use this definition.				
Brian Evans-Mongeon	Utility Services, Inc.	8	Negative	see filed comments
Response: Thank you for your comments. The SDT changed the definition following the formal comment period that ended July 16, 2010; there was no formal comment period during the second ballot of the proposed definition.				
Glen Reeves	Salt River Project	5	Affirmative	SRP believes the requirements of the Standard are confusing and may be problematic in determining compliance. We also believe the required functional testing of the breaker trip coil may potentially increase maintenance outages of circuit breakers. In most cases, circuit breaker maintenance outages can be coordinated such that Protection System maintenance and testing can be done simultaneously. However, in some cases this may not be possible. Outages of any BES facility whether planned or unplanned can impact system reliability. SRP suggests that trip coil monitoring devices be included as an acceptable means of ensuring the trip coil is functioning properly. This will help to avoid unnecessary outages.
Response: Thank you for your comments. Your comments appear to be relative to the draft standard PRC-005-2, rather than the definition. The SDT had not completed the consideration of comments on the standard when the definition was re-posted. The SDT provides the following response, in accordance with the responses to comments on the standard itself.				
James V. Petrella	Atlantic City Electric Company	3	Affirmative	Suggested improvement: add "and associated circuitry" to "Voltage and current sensing devices and associated circuitry providing inputs to protective relays".

Voter	Entity	Segment	Vote	Comment
Response: Thank you for your comments. Many other commenters have previously expressed concern with the definition as you suggest, and the SDT believes that the definition as currently posted best expresses this portion of the definition.				
Thomas R. Glock	Arizona Public Service Co.	3	Negative	The change to the definition relative to the voltage and current sensing devices is too prescriptive. Methods of determining the integrity of the voltage and current inputs into the relays to ensure reliability of the devices should be up to the discretion of the utility.
Response: Thank you for your comments. Absent any specific comment regarding how the definition is too prescriptive, the SDT is unable to respond to your concerns. Your comments appear to be relative to the draft standard PRC-005-2, rather than the definition. The SDT had not completed the consideration of comments on the standard when the definition was re-posted. The SDT has responded to similar comments within the responses to ballot comments and the consideration of comments on the standard itself.				
William D Shultz	Southern Company Generation	5	Negative	The definition alone is acceptable, but the existing version of PRC-005 does not guarantee any additional maintenance or testing will occur with its ratification. Maintenance methodology documents will have to be revised to include the new definition, but entities may still dictate limited maintenance activities and lengthy intervals which require no additional maintenance to be done. The PRC-005-2 version of the standard includes this revised definition and requires specific maintenance activities at specific intervals. Establishing only a new definition does not close the perceived reliability gap that is the basis for the current vote. The new definition needs to be ratified along with the revised standard.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.				
Raj Rana	American Electric Power	3	Negative	The definition as drafted includes "Station dc supply." While this appears reasonable and innocuous, the term is unclear and could be construed by an auditor to include a lot of equipment and infrastructure not intended by the PSMT SDT. For example, station battery chargers are typically supplied by station auxiliary power transformers, which in turn are supplied by primary-voltage bus work, primary-voltage fuses, or primary-voltage circuit breakers.

Voter	Entity	Segment	Vote	Comment
				An auditor for either PRC-005 or any other Standard referencing "Protection System" could read that such primary-voltage equipment is part of the Protection System and therefore subject to certain requirements in either PRC-005 or any other Standard referencing Protection System. The definition as drafted includes "Communications systems necessary. . . ". Once again, this term appears innocuous, but it is actually unclear. For example, if a transfer-trip channel is carried on a microwave path, an auditor may decide that the entire microwave equipment, microwave building battery, and microwave building emergency generator are all part of the Protection System, and thus subject to requirements in either PRC-005 or other existing or future Standards that refer to Protection System. AEP recommends that the term be phrased "communications paths" opposed to "communications systems". Similar to the above two items, we are concerned about the inclusion of voltage and current-sensing "devices" in the Definition. As written, applicability can be inferred to the entire device and not merely its output quantities, not only for this Standard but any other that references a Protection System. AEP recommends the phrase "circuitry from voltage and current-sensing devices providing inputs to protective relays" instead of "voltage and current-sensing devices providing inputs to protective relays"
Response: Thank you for your comments. The definition has been modified to specifically include battery chargers. As to your other comments, it appears that your comments apply more to the application of the definition within PRC-005-1 or PRC-005-2 than they do to the definition itself. Within the reference materials associated with PRC-005-2, the SDT advises that equipment associated with microwave systems is part of the communications system. The SDT believes that the proposed definition is less vague than the current definition on the issues you cite, and would improve the situation that you discuss from the current level.				
Michael Moltane	International Transmission Company Holdings Corp	1	Negative	The definition contained in this ballot really needs to be part and parcel of the PRC-005-2 Standard Ballot, since the definition has such a huge impact on the standard itself. It is problematic to vote on a definition and on the standard independent of one another. Therefore, ITC must vote negative on this Ballot.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical				

Voter	Entity	Segment	Vote	Comment
- not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.				
Michael Schiavone	Niagara Mohawk (National Grid Company)	3	Affirmative	The definition could be worded better
Response: Thank you for your comments. The SDT has modified the definition for improved clarity.				
Kenneth Parker	Entegra Power Group, LLC	5	Negative	The definition infers testing of CTs and PTs which should not be necessary.
Response: Thank you for your comments. The definition of Protection System is for all applications of this term throughout NERC Standards. The detailed applicability of this element of the definition relative to maintenance within PRC-005-2 is addressed within the standard by specifying, "Verify that acceptable measurements of the current and voltage signals are received by the protective relays".				
Christopher Plante	Integrys Energy Group, Inc.	4	Negative	1. The definition should state what is meant by "station dc supply". There continues to be questions in the industry regarding if dc supply includes the battery charger. We believe the charger is not included in station dc supply and that the Definition of Protection System should specifically address the point. 2. Also, the definition should specify BES relays, BES protection functions and elements associated with BES relays and functions.
Response: Thank you for your comments. 1. The definition has been modified to specifically include battery chargers. 2. This is properly an issue to address in the various standards that use this definition.				
Terry Harbour	MidAmerican Energy Co.	1	Negative	The following changes should be incorporated in the definition to insure it is used consistently in PRC-005 and any other standards where it appears. Revise Protection System definition to: o BES Protective relays which respond to electrical quantities, o Communications systems necessary for correct operation of the BES protective functions, o Voltage and current sensing devices providing inputs to BES protective relays, o Battery and battery chargers that supply dc to BES protective relays, communications, and control circuitry, and Control circuitry associated with the BES

Voter	Entity	Segment	Vote	Comment
				protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.
Response: Thank you for your comments. The station dc supply component type has been modified essentially as you suggest. As to your suggestion regarding inclusion of "BES' within the definition – this is properly an issue to address in the various standards that use this definition.				
Robert W. Roddy	Dairyland Power Coop.	1	Negative	The implementation of the revised definition should not take place until the revised standard PRC-005-2 is in effect.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.				
John Tolo	Tucson Electric Power Co.	1	Negative	The mention of communication systems maintenance (M1.) needs more clarity as to the depth of the maintenance required. Also, Table 1a, a 3-month interval to verify that the Protection System communications system is functional is too frequent to be practical.
Response: Thank you for your comments. Your comments do not seem relevant to the definition, but instead appear to be related directly to the revisions to the draft PRC-005-2 itself. The SDT had not completed consideration of comments on the standard when the definition was re-posted. The SDT provides the following response, in accordance with the responses to comments on the standard itself.				
Scott Kinney	Avista Corp.	1	Negative	The modified definition of Protection System now refers to "functions" rather than "devices." What are the "functions?" This new term adds confusion without being defined in the standard.
Response: Thank you for your comments. The reference to "functions" is intended to reflect that there is increasing use, particularly in SPS, of devices which mimic protective relays but are not actually traditional relays.				
Michael Gammon	Kansas City Power & Light Co.	1	Negative	The proposed changes in the Standard are far too prescriptive and do not take into account the multitude of manufacturers

Voter	Entity	Segment	Vote	Comment
Charles Locke	Kansas City Power & Light Co.	3	Negative	equipment by establishing broad maintenance cycles and testing intervals.
Scott Heidtbrink	Kansas City Power & Light Co.	5	Negative	
Thomas Saitta	Kansas City Power & Light Co.	6	Negative	
Response: Thank you for your comments. Your comments appear to be relative to the draft standard PRC-005-2, rather than the definition. In Order 693, the FERC directed that NERC establish maximum allowable intervals for maintenance of protection systems.				
Jack Stamper	Clark Public Utilities	1	Negative	The proposed definition does not provide the level of clarity that is needed.
Response: Thank you for your comments. The SDT has modified the definition for improved clarity.				
Ajay Garg	Hydro One Networks, Inc.	1	Affirmative	The proposed definition of Protection System needs clarification on when such equipment is a part of the transmission protection system. Emphasis should be on systems and not individual components.
Response: Thank you for your comments. This issue is better addressed in the various standards that use the definition.				
Mace Hunter	Lakeland Electric	3	Affirmative	The proposed draft may introduce TFEs into the PRC standards, not a good thing. The proposed draft reaches beyond the statutory scope of the reliability standards. Perfection is not a realistic goal.
Response: Thank you for your comments. The SDT has modified the definition for improved clarity.				
Kim Warren	Independent Electricity System Operator	2	Affirmative	The proposed revision to the definition has removed the "associated circuitry from the voltage and current sensing devices" which we believe should be included since failure of this wiring will render the Protection System inoperative. On this basis we recommend the following change to once again include this circuitry in the definition: “Protective relays which respond to electrical quantities, communication systems necessary for correct operation of protective functions, voltage and current sensing devices AND ASSOCIATED CIRCUITRY [emphasis added] providing inputs to protective relays, station dc supply, and control circuitry

Voter	Entity	Segment	Vote	Comment
				associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.”
Response: Thank you for your comments. The change to insert the term “devices providing” was to improve clarity while also excluding voltage and current measuring devices that provide data exclusively to metering equipment as opposed to Protection Systems. The SDT agrees with the commenter that an appropriate maintenance activity is to ensure that the measured voltage and current values correctly make it to the relays. The maintenance activity is a part of the standard. The absence of this activity from the definition is not intended to lead one to believe that the activity is not important.				
Roger C Zaklukiewicz		8	Negative	The proposed rewording of the definition implies that the wiring from the current transformers and voltage transformers to the protective relay systems are independent of the protection system being tested and that separate maintenance standards will have to be established to test the integrity of the wiring and the Potential device and current transformer. The definition of the Protection System should not exclude the wiring and devices which generate the current and voltage sources to the protective relays.
Response: Thank you for your comments. The change to insert the term “devices providing” was to improve clarity while also excluding voltage and current measuring devices that provide data exclusively to metering equipment as opposed to Protection Systems. The SDT agrees with the commenter that an appropriate maintenance activity is to ensure that the measured voltage and current values correctly make it to the relays. The maintenance activity is a part of the standard. The absence of this activity from the definition is not intended to lead one to believe that the activity is not important.				
Jim R Stanton	SPS Consulting Group Inc.	8	Negative	The reference to "communication systems" should be deleted from the definition. It is confusing to Registered Entities who do not consider the circuits that connect components of a protection system to be a communication "system" such as a telephone system, postal service or computer network which is more properly called a communication system. Suggest changing it to "signal carrying circuitry."
Response: Thank you for your comments. The SDT believes that “Communication Systems” is a term that is generally well understood within the industry.				

Voter	Entity	Segment	Vote	Comment
Brock Ondayko	AEP Service Corp.	5	Negative	The term "station" should either be defined or removed from the definition, as it implies transmission and distribution assets while the term "plant" is used to define generation assets. It would suffice to simply refer to the "DC Supply". As written, the implementation plan only specifies a time frame for entities to update their documentation for PRC-005-1 and PRC-005-2 compliance. The implementation plan also needs to give entities a time frame to address any required changes to their documentation for other standards that use the term "Protection System", including but not limited to NUC-001-2, PER-005-1, PRC-001-1, etc.
Response: Thank you for your comments. The term 'station' was used because it could include both a substation and a generation station while at the same time excluded installations that were strictly communications repeater sites. As noted on the "Assessment of Impact of Proposed Modification to the Definition of "Protection System" which was posted with the first comment period, the SDT believes that the bulk of the implementation of the new definition will be regarding PRC-005 (generically) and that there will be very little implementation associated with the other standards that utilize this term.				
Paul B. Johnson	American Electric Power	1	Negative	1. The term "station" should either be defined or removed from the definition, as it implies transmission and distribution assets while the term "plant" is used to define generation assets. It would suffice to simply refer to the "DC Supply". As written, the implementation plan only specifies a time frame for entities to update their documentation for PRC-005-1 and PRC-005-2 compliance. The implementation plan also needs to give entities a time frame to address any required changes to their documentation for other standards that use the term "Protection System", including but not limited to NUC-001-2, PER-005-1, PRC-001-1, etc. we still support a "negative" ballot with the following comments: 2. The definition as drafted includes "Station dc supply." While this appears reasonable and innocuous, the term is unclear and could be construed by an auditor to include a lot of equipment and infrastructure not intended by the PSMT SDT. For example, station battery chargers are typically supplied by station auxiliary power transformers, which in turn are supplied by primary-voltage buswork, primary-voltage fuses, or primary-voltage circuit

Voter	Entity	Segment	Vote	Comment
				breakers. An auditor for either PRC-005 or any other Standard referencing "Protection System" could read that such primary-voltage equipment is part of the Protection System and therefore subject to certain requirements in either PRC-005 or any other Standard referencing Protection System. The definition as drafted includes "Communications systems necessary. . . ". Once again, this term appears innocuous, but it is actually unclear. For example, if a transfer-trip channel is carried on a microwave path, an auditor may decide that the entire microwave equipment, microwave building battery, and microwave building emergency generator are all part of the Protection System, and thus subject to requirements in either PRC-005 or other existing or future Standards that refer to Protection System Similar to the above two items, we are concerned about the inclusion of voltage and current-sensing "devices" in the Definition. As written, applicability can be inferred to the entire device and not merely its output quantities, not only for this Standard but any other that references a Protection System.
Response: Thank you for your comments. 1. The term 'station' was used because it could include both a substation and a generation station while at the same time excluded installations that were strictly communications repeater sites. As noted on the "Assessment of Impact of Proposed Modification to the Definition of "Protection System" which was posted with the first comment period, the SDT believes that the bulk of the implementation of the new definition will be regarding PRC-005 (generically) and that there will be very little implementation associated with the other standards that utilize this term. 2. The definition has been modified to specifically include battery chargers. As to your other comments, it appears that your comments apply more to the application of the definition within PRC-005-1 or PRC-005-2 than they do to the definition itself. Within the reference materials associated with PRC-005-2, the SDT advises that equipment associated with microwave systems is part of the communications system. The SDT believes that the proposed definition is less vague than the current definition on the issues you cite, and would improve the situation that you discuss from the current level.				
Peter T Yost	Consolidated Edison Co. of New York	3	Negative	1. There is not enough clarity on whether a Distribution Provider (DP) will be able to clearly identify which protection system components it does own and needs to maintain. Many DPs own and/or operate equipment identified in the existing or proposed definition. However, not all such equipment translates into a transmission Protection System. The definition needs clarification on when such equipment is a part of the transmission protection system.

Voter	Entity	Segment	Vote	Comment
				2. Also, the time provided for the first phase "at least six months" is too open ended and does not provide entities with a clear timeline. It is suggested that one year is appropriate for the first phase phasing out the second year in stages.
Response: Thank you for your comments. 1. Your comments appear to be relative to the draft standard PRC-005-2, rather than the definition. The SDT had not completed the consideration of comments on the standard when the definition was re-posted. The SDT has responded to similar comments within the responses to ballot comments and the consideration of comments on the standard itself. “When such equipment is part of the transmission protection system” is properly a matter to be resolved within the various standards that use this term. 2. The implementation period has been revised from six months to twelve months.				
Greg Lange	Public Utility District No. 2 of Grant County	3	Negative	These systems are not always maintained at the component level. ie. meggering from the relay input test switch through the cable and the CT. This has not closed all the issues around professional judgement (interpretations) that make us nervous when faced with the human element of an audit. We need more specificity to close that gap.
Response: Thank you for your comments. Your comments appear to be relative to the draft standard PRC-005-2, rather than the definition. The SDT had not completed the consideration of comments on the standard when the definition was re-posted. The SDT has responded to similar comments within the responses to ballot comments and the consideration of comments on the standard itself.				
Silvia P Mitchell	Florida Power & Light Co.	6	Affirmative	This revision is better written.
Response: Thank you for your comments.				

Voter	Entity	Segment	Vote	Comment
Joseph G. DePoorter	Madison Gas and Electric Co.	4	Negative	Upon review of the updated proposed “Protection System” definition and its main use in describing PRC-005, which applies to BES Protective Systems, the definition needs to incorporate BES within it. Without BES used within the definition, it will be used to interpret every protection system that the industry uses. This is not the course that we wish to travel. Please note the following recommended definition: o BES Protective relays which respond to electrical quantities, o Communications systems necessary for correct operation of the BES protective functions, o Voltage and current sensing devices providing inputs to BES protective relays, o Battery and battery chargers that supply dc power to BES protective relays, communications, and control circuitry, and o Control circuitry associated with the BES protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.
Response: Thank you for your comments. The station dc supply component type has been modified essentially as you suggest. As to your suggestion regarding inclusion of “BES’ within the definition – this is properly an issue to address in the various standards that use this definition.				
Richard J. Mandes	Alabama Power Company	3	Affirmative	We agree that the definition provides clarity and will enhance the reliability of the Protection Systems to which it is applicable. However, we feel that there needs to be a direct linkage of the definition’s effective date to the approval and implementation schedule of PRC-005-2. Since this new definition is directly linked to the proposed revised standard, it would be premature to make this definition effective prior to the effective date of the new standard.
Anthony L Wilson	Georgia Power Company	3	Affirmative	
Gwen S Frazier	Gulf Power Company	3	Affirmative	
Don Horsley	Mississippi Power	3	Affirmative	
Horace Stephen Williamson	Southern Company Services, Inc.	1	Affirmative	
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.				
Jason L Marshall	Midwest ISO, Inc.	2	Abstain	We are abstaining because a number of our stakeholders have concerns regarding the definition of Protection System.
Response: Thank you for your comments. The SDT responded to the individual stakeholder comments submitted.				

Voter	Entity	Segment	Vote	Comment
Claudiu Cadar	GDS Associates, Inc.	1	Negative	We do not agree with inclusion of the trip coil. The trip coil is not a protective device; it does not sense voltage or current and operates based on a faulted condition. It is supplied the necessary input from the DC system which is based on protective relays signaling and contact operation. The trip coil is part of the circuit breaker; it is not separate equipment. Does this mean that the circuit breaker is now part of the protection system?
Response: Thank you for your comments. The current definition includes “DC Control Circuitry”; the SDT attempted to clearly define which of the many control circuits and the limit of the definition. While the current definition is vague, it can certainly include the trip coils and close coils and alarm circuits of the interrupting device. The SDT believes that the electrically-operated trip coils are an important part of the control circuitry.				
Anthony Jankowski	Wisconsin Energy Corp.	4	Negative	We Energies does not agree to the implementation plan proposed. While it makes common sense to proceed with R1 prior to proceeding with implementing R2, R3, and R4, the timeline to be compliant for R1 is too short. It will take a considerable amount of resources to migrate the maintenance plan from today’s standard to the new standard in phase one. ATC recommends that time to develop and update the revised program be increased to at least one year followed by a transition time for the entity to collect all the necessary field data for the protection system within its first full cycle of testing. (In ATC’s case would be 6 years) To address phase two, We Energies believes human and technological resources will be overburdened to implement this revised standard as written. The transition to implementing the new program will take another full testing cycle once the program has been updated. Increased documentation and obtaining additional resources to accomplish this will be challenging. Implementation of PRC-005-2 will impact We Energies in the following manner: a. Increase costs: double existing maintenance costs. b. Since there will be a doubling of human interaction (or more), it is expected that failures due to human error will increase, possibly proportionately. c. Breaker maintenance may need to be aligned with protection scheme testing, which will always contain elements that are include in the non-monitored table for 6 yr testing. d. We Energies is developing standards for redundant bus and transformer protection schemes. This would allow We Energies to

Voter	Entity	Segment	Vote	Comment
				test the protection packages without taking the equipment out of service. Further if one system fails, there is full redundancy available. With the current version of PRC-005-2, We Energies would need to take an outage to test the protection schemes for a transformer or a bus, there is not an incentive to install redundant schemes. We Energies is working with a condition based breaker maintenance program. This program's value would be greatly diminished under PRC-005-2 as currently written. Consideration also needs to be given for other NERC standards expected to be passed and in the implementation stage at the same time, such as the CIP standards.
Response: Thank you for your comments. Your comments appear to be relative to the draft standard PRC-005-2, rather than the definition. The SDT had not completed the consideration of comments on the standard when the definition was re-posted. The SDT has responded to similar comments within the responses to ballot comments and the consideration of comments on the standard itself.				
Linda Horn	Wisconsin Electric Power Co.	5	Negative	We object strongly to the addition of the term "voltage and current sensing devices...". This revised definition will make it a requirement to perform actual tests on the voltage and current transformers. The previous definition was "voltage and current inputs to protective relays" and this is much preferred to allow the needed flexibility in maintenance practices.
James R. Keller	Wisconsin Electric Power Marketing	3	Negative	
Response: Thank you for your comments. The current definition of Protection System uses the term "voltage and current sensing devices". The current standard PRC-005-1 requires the entity to have a PSMP for those devices. The proposed revision PRC-005-2 would require minimum maintenance activities that verify other than an annual IR Scan of the voltage and current sensing devices. As there is no method listed in the standard, some of the process flexibility that you seek has been maintained.				
Brandy A Dunn	Western Area Power Administration	1	Affirmative	Western agrees with the revised definition of a Protection System and disagreese with the Implementation Plan under PRC-005-1. The definition implementation should be delayed until approval of PRC-005-2.
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give				

Voter	Entity	Segment	Vote	Comment
entities time to apply the new definition to PRC-005-1.				
Henry Delk, Jr.	SCE&G	1	Negative	While SCE&G believes the majority of the PRC-005-2 standard is ready to be affirmed there are still inconsistencies with areas of the standard that need to be corrected prior to approval. These inconsistencies are addressed in SCE&G's comments which have been submitted for the current draft of this standard.
Response: Thank you for your comments. Your comments appear to be relative to the draft standard PRC-005-2, rather than the definition. The SDT had not completed the consideration of comments on the standard when the definition was re-posted. Please see the response to your comments on the first draft of the standard.				
Richard J Kafka	Potomac Electric Power Co.	1	Affirmative	While voting in the affirmative, PHI feels the definition could be improved by adding and associated circuitry to the third item Voltage and current sensing devices and associated circuitry providing inputs to protective relays
Response: Thank you for your comments. The SDT agrees with the commenter of the importance of this as a maintenance activity and has attempted to capture relevant maintenance activities within the revised standard itself.				
David A. Lapinski	Consumers Energy	3	Negative	Without the context of draft PRC-005-2, the changes to this definition are difficult to understand and even more difficult to implement. We therefore strongly recommend that this definition NOT be approved independently from the draft of PRC-005-2, and that development of both the definition and the standard proceed as a single activity.
David Frank Ronk	Consumers Energy	4	Negative	
Response: Thank you for your comments. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.				
Gregory L Pieper	Xcel Energy, Inc.	1	Negative	Xcel Energy believes the standard still contains many aspects that are not clearly understood by entities, including what is needed to demonstrate a compliant PSMP. Comments have been submitted concurrently to NERC via the draft comment response form.
Michael Ibold	Xcel Energy, Inc.	3	Negative	
Response: Thank you for your comments. Your comments appear to be relative to the draft standard PRC-005-2, rather than the definition. The SDT had not completed the consideration of comments on the standard when the definition was re-posted. Please see the response to your comments on the first draft of				

Voter	Entity	Segment	Vote	Comment
the standard.				
James A Ziebarth	Y-W Electric Association, Inc.	4	Affirmative	Y-WEA thanks the SDT for clarifying what relays are and are not included in this definition.
Response: Thank you for your comments.				

Proposed Definition of Protection System:

Protection System –

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

Protection System Definition

The definition posted for the second ballot of Protection System reads as follows:

Protection System –

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply, and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

Based on stakeholder comments submitted with the second ballot, the drafting team made minor changes to the proposed definition as shown below:

Protection System –

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

Protection System Definition

The previously approved (Board of Trustees) definition of Protection System reads as follows:

Protection System: Protective relays, associated communication systems, voltage and current sensing devices, station batteries and DC control circuitry.

Proposed Changes to Board of Trustees Approved Version of Definition:

Protection System: Protective relays which respond to electrical quantities, ~~associated~~ communication systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays, station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery based ~~and DC~~ dc supply), and control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

Implementation Plan for the Revised Definition of Protection System

Prerequisite Approvals or Activities:

The implementation of the revised definition is not dependent upon any other activity.

Recommended Modifications to Already Approved Standards

The non-capitalized version of the term, "protection system" is used in the following approved standards:

- NUC-001-2 – Nuclear Plant Interface Coordination
- PER-005-1 – System Personnel Training
- PRC-001-1 – System Protection Coordination

The term, "protection system" shall be capitalized where used in these standards when the definition of "Protection System" is approved by applicable regulatory authorities.

Proposed Effective Date:

Each responsible entity (Distribution Provider that owns a transmission Protection System, Transmission Owner, and Generator Owner) shall modify its protection system maintenance and testing program description and basis document(s) (required in Requirement R1 of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing) as necessary to reflect the modified definition of 'Protection System' by the first day of the first calendar quarter twelve months following regulatory approvals and implement any additional maintenance and testing (required in Requirement R2 of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing) by the end of the first complete maintenance and testing cycle described in the entity's program description and basis document(s) following establishment of the program changes resulting from the revised definition.

The original definition of "Protection System" shall be retired at the same time the revised definition becomes effective.

Comment Form for the definition of Protection System [Project 2007-17]

Please **DO NOT** use this form to submit comments on the proposed definition of "Protection System." Comments must be submitted by **October 12, 2010**. If you have questions please contact Al McMeekin at al.mcmeekin@nerc.net or by telephone at 803-530-1963.

Background Information:

A second ballot for the definition of "Protection System" was conducted from July 23 – August 2, 2010. There were numerous comments opposing balloting the definition separately from the definition; the NERC Board of Trustees directed that a revised definition be approved as quickly as possible to close a reliability gap.

Some commenters suggested the "station dc supply" portion of the definition be modified to specifically address battery chargers; the SDT modified the definition as suggested. The revised definition is shown below with the new language shown in red:

Protection System –

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The SDT did not make any other modifications to the definition and did not make any modifications to the implementation plan following the second ballot. The implementation plan allows at least 12 months beyond the regulatory approval date for entities to implement the new definition.

1. Do you agree with the proposed definition of "Protection System?" If not, please provide specific suggestions for improvement.

   ☐ Yes

   ☐ No

Standards Announcement

Successive Ballot Open
October 2-14, 2010

Available at: https://standards.nerc.net/CurrentBallots.aspx

Project 2007-17 Protection System Maintenance Definition

A successive ballot for the definition of "Protection System" is now open through **8 p.m. Eastern on October 14, 2010**.

Instructions

Members of the ballot pool associated with this project may log in and submit their votes from the following page: https://standards.nerc.net/CurrentBallots.aspx

The Standards Committee encourages all members of the ballot pool to review the consideration of comments for the previous ballot and the modifications that team made to the definition. In a successive ballot, votes are not carried forward from the previous ballot.

Transition from Reliability Standards Development Procedure Version 7 – to Standard Processes Manual

Under the Reliability Standards Development Procedure Version 7, consensus was built with successive formal comment periods, followed by a 30-day pre-ballot review, followed by an initial ballot, and then a recirculation ballot. The intent was to use stakeholder views submitted through the formal comment periods to achieve consensus, and then to confirm that consensus during the balloting. This process did not allow a drafting team to make any changes to a standard (or definition) between ballots, which incented teams to avoid making improvements once a standard (or definition) had gone through an initial ballot. If a team made a change between ballots, then the standard (or definition) was required to be posted for a new comment period and then another pre-ballot review and another initial ballot, and finally if there were no more changes made to the standard (or definition), a recirculation ballot was conducted to confirm consensus.

Under the new Standard Processes Manual, consensus is achieved through parallel comment and ballot periods. Successive comment and ballot periods are conducted until there is consensus – and then a recirculation ballot is conducted to confirm that consensus. There is no 30-day pre-ballot review period, and drafting teams are encouraged to make revisions to the standard between successive ballots to improve the quality of the standard (or definition).

Next Steps

Voting results will be posted and announced after the ballot window closes.

Project Background

When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the Protection System and Maintenance Standard Drafting Team, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given “priority.” The Standards Committee directed the team to advance the definition of Protection System in parallel with the development of PRC-005-2.

Standards Announcement

Successive Formal Comment Period Open
September 13 – October 12, 2010

Now available at:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Project 2007-17: Protection System Maintenance and Testing

A formal comment period for the revised definition of "Protection System" is now open **until 8 p.m. Eastern on October 12, 2010.**

This is the fourth draft of the proposed definition. As envisioned, the definition, once approved, will apply to PRC-005-1 approximately twelve months following regulatory approval. The new definition will replace the existing definition of "protection system." The existing definition has some identified deficiencies that result in a reliability gap, where some protection system owners do not consider components such as battery chargers associated with protective functions as components of a protection system, and do not include the maintenance of these components in their protection system maintenance programs.

Transition from Reliability Standards Development Procedure Version 7 – to Standard Processes Manual

Under the Reliability Standards Development Procedure Version 7, consensus was built with successive formal comment periods, followed by a 30-day pre-ballot review, followed by an initial ballot, and then a recirculation ballot. The intent was to use stakeholder views submitted through the formal comment periods to achieve consensus, and then to confirm that consensus during the balloting. This process did not allow a drafting team to make any changes to a standard (or definition) between ballots, which incented teams to avoid making improvements once a standard (or definition) had gone through an initial ballot. If a team made a change between ballots, then the standard (or definition) was required to be posted for a new comment period and then another pre-ballot review and another initial ballot, and finally if there were no more changes made to the standard (or definition), a recirculation ballot was conducted to confirm consensus.

Under the new Standard Processes Manual, consensus is achieved through parallel comment and ballot periods. Successive comment and ballot periods are conducted until there is consensus – and then a recirculation ballot is conducted to confirm that consensus. There is no 30-day pre-ballot review period, and drafting teams are encouraged to make revisions to the standard between successive ballots to improve the quality of the standard (or definition).

Instructions

Please use this electronic form to submit comments. If you experience any difficulties in using the electronic form, please contact Monica Benson at monica.benson@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Next Steps

During the last 10 days of the 30-day formal comment period a successive ballot will be conducted for 10 days. All members of the ballot pool must cast a new ballot – the votes and comments from the last ballot will not be carried over. The drafting team will consider all comments (those submitted with a comment form, and those submitted with a ballot) and will determine whether to make additional changes to the definition. The team will post its response to comments and, if the definition has only minor changes, will post the definition and conduct a 10-day recirculation ballot.

Project Background

When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the Protection System and Maintenance Standard Drafting Team, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." The Standards Committee directed the team to advance the definition of Protection System in parallel with the development of PRC-005-2.

Standards Announcement
Successive Ballot Results

Now available at: https://standards.nerc.net/Ballots.aspx

Project 2007-17 Protection System Maintenance Definition
A successive ballot for the definition of "Protection System" ended **on October 14, 2010**.

Successive Ballot Results
Voting statistics are listed below, and the Ballot Results Web page provides a link to the detailed results:

Quorum: 84.11%

Approval: 84.52 %

Since at least one negative ballot included a comment, these results are not final. Another ballot (either a successive ballot or a recirculation ballot) must be conducted.

Transition from Reliability Standards Development Procedure Version 7 – to Standard Processes Manual
Under the Reliability Standards Development Procedure Version 7, consensus was built with successive formal comment periods, followed by a 30-day pre-ballot review, followed by an initial ballot, and then a recirculation ballot. The intent was to use stakeholder views submitted through the formal comment periods to achieve consensus, and then to confirm that consensus during the balloting. This process did not allow a drafting team to make any changes to a standard (or definition) between ballots, which incented teams to avoid making improvements once a standard (or definition) had gone through an initial ballot. If a team made a change between ballots, then the standard (or definition) was required to be posted for a new comment period and then another pre-ballot review and another initial ballot, and finally if there were no more changes made to the standard (or definition), a recirculation ballot was conducted to confirm consensus.

Under the new Standard Processes Manual, consensus is achieved through parallel comment and ballot periods. Successive comment and ballot periods are conducted until there is consensus – and then a recirculation ballot is conducted to confirm that consensus. There is no 30-day pre-ballot review period, and drafting teams are encouraged to make revisions to the standard between successive ballots to improve the quality of the standard (or definition).

Next Steps
The drafting team will review the comments submitted with ballots and post its consideration of those comments.

Project Background

When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the Protection System and Maintenance Standard Drafting Team, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given “priority.” The Standards Committee directed the team to advance the definition of Protection System in parallel with the development of PRC-005-2.

Project Page: http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Ballot Criteria

Approval requires both a (1) quorum, which is established by at least 75% of the members of the ballot pool submitting either an affirmative vote, a negative vote, or an abstention, and (2) a two-thirds majority of the weighted segment votes cast must be affirmative; the number of votes cast is the sum of affirmative and negative votes, excluding abstentions and non-responses. If there are no negative votes with reasons from the first (or successive) ballot, the results of that ballot shall stand. If, however, one or more members submit negative votes with reasons, another ballot shall be conducted. If the team makes significant changes to the definition, then another successive ballot must be conducted. If the team does not make any significant changes to the definition, then a final recirculation ballot is conducted.

Standards Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

The revised definition perpetuates the confusion over "communications systems" embedded or otherwise associated with Protection Systems. The term "communications components" is more accurate.
Individual
Martin Bauer
US Bureau of Reclamation
No
The term "protection functions" is ambiguous as it is not related to the protection function associated with the protective relays. There are other protection functions not associated with protective relays that respond to electrical quantities. The language for Communication systems should be changed to remove the ambiguity. The following change would be clear, "Communication system necessary for the correct operation of the protective relays" The input to the relays is from voltage and current sensing devices through their respective circuits. Since the definition for protective relays separates the term "control circuitry" associated with protective relays, it is clear that protective relays does not also include the "control circuitry". By the same token, voltage and current sensing devices do not include their related circuits. The definition for voltage and current sensing devices should be revised to include the term "circuits". The following language change would serve make it clear: "Voltage and current sensing devices and their respective circuits providing inputs protective relays,".
Individual

US Army Corps of Engineers
No
The use of the term "protection functions" is not a defined NERC term and either the term should be defined or it should not be used. At best the term is ambiguous and could lead to scope growth by auditors. Recommend that the following changes be made: "Communication system necessary for the correct operation of the protective relays." "Control circuitry associated with protective relays through the trip coil(s) of the circuit breaker or other interrupting device." See the next paragraph for the proposed correction to the DC Supply part of the definition. The input to the relay is from voltage and currenct sensing devices yet there is no mention of the associated circuits. The same can be said about the station DC supply circuits. The definition should apply to the circuits providing inputs or control power to the protective relays and from the output of the relays to the tripping coils of the circuit breaker. Recommend the following: "Voltage and current sensing devices and their respective circuits providing inputs to the protective relays." "Station DC supply associated with protective relays (including station batteries, battery charger, non-battery-based DC supply,circuitry to the protective relays and from the relay to the trip coil(s)of the circuit breaker), and"

NERC Staff
Mallory Huggins
No
NERC staff does not support the phrase “voltage and current sensing devices providing input to protective relays.” While no version of the definition has been all-inclusive with respect to this phrase.

we believe that the best phrase would be a combination of several drafts and should state the following: “voltage and current sensing devices and associated circuitry from the voltage and current sensing devices to the protective relay inputs.” As currently written, the definition represents a step backward from the language in the previous definition (“voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices”) and should be modified.

This project addresses the definition of a Protection System. However, an ongoing issue that needs to be addressed is clarification of when a Bulk Electric System transmission Protection System applies to a Distribution Provider. An example would be for a tee-tap off a Bulk Power System 345kV line to a step down transformer supplying distribution--would the relaying on the low side of the transformer be expected to comply with the requirements of PRC-005-2? Would the protection system configuration be considered a Protection System? Will this issue be addressed within the scope of Project 2007-17?

The majority of the definition is good; however, the term "non-battery-based dc supply' is still somewhat vague. Can you please further define or provide some examples?
Individual
Paul Rocha
CenterPoint Energy
No
(a) CenterPoint Energy believes the proposed re-definition of “Protection System” is technically incorrect due to the inclusion of trip coils as part of the control circuitry. A protection system has correctly performed its function if it provides tripping voltage up to the terminals of trip coils. From that point, the circuit breaker can fail to timely interrupt fault current due to several factors, such as a binding mechanism, stuck mechanism, broken pull rod, bad insulating medium, or bad trip coils. Local breaker failure protection, or remote backup protection, is installed to address the various possible causes of circuit breaker failure. The proposed re-definition of “Protection System” should be revised to indicate control circuitry associated with protective functions UP TO THE TERMINALS OF the trip coil(s) of the circuit breakers or other interrupting devices. (b) On the surface, the proposed re-definition of “Protection System” appears mainly applicable to PRC-005 based upon the Standards

Announcement and proposed Implementation Plan. However, NERC standard PRC-004-1 Analysis and Mitigation of Transmission and Generation Protection System Misoperations also uses the capitalized term “Protection System”. CenterPoint Energy believes it is inappropriate to require reporting of Misoperations of transmission Protection Systems and generator Protection Systems for bad trip coils within a circuit breaker. For application to PRC-004-1, CenterPoint Energy recommends revising the proposed re-definition to indicate control circuitry associated with protective functions UP TO THE TERMINALS OF the trip coil(s) of the circuit breakers or other interrupting devices.

This change in definition needs to occur concurrently with other related projects (PRC-005-2). The SDT nor the SC should establish a practice of making changes to definitions outside the parameters of changes to standards. This will introduce opportunities to confuse and does not provide the appropriate signals to the Registered Entities to adjust their programs and make the appropriate changes. If this has to be done faster than the pace of the current PRC-005-2 project, we suggest it still be paired with that project, but a smaller scope be considered to allow for this to pass quickly as possible and then the remaining work can be accomplished in PRC-005-3. We suggest that the SDT consider the creation of sub-definitions opposed to crafting a single term for complex and diverse components that could make up the “Protection System.” As it stands, AEP cannot support this as it still does not remove the degree of ambiguity that could result in interpretation challenges during later enforcement and monitoring activities. We understand the urgency to make progress; however, the deliverables of this team can have significant collateral impacts in the compliance process. The bullet for Protective relays should be further clarified with the addition of “applied on or designed to provide protection for the BES that respond to the electrical fault or disturbance conditions.” Below are the comments that were provided in the second draft that were not adequately addressed in the consideration of the comments. The definition as drafted includes "Station dc supply." While this appears reasonable and innocuous, the term is unclear and could be construed by an auditor to include a lot of equipment and infrastructure not intended by the PSMT SDT. For example, station battery chargers are typically supplied by station auxiliary power transformers, which in turn are supplied by primary-voltage bus work, primary-voltage fuses, or primary-voltage circuit breakers. An auditor for either PRC-005 or any other Standard referencing "Protection System" could read that such primary-voltage equipment is part of the Protection System and therefore subject to certain requirements in either PRC-005 or any other Standard referencing Protection System. The definition as drafted includes "Communications systems necessary. . . ". Once again, this term appears innocuous, but it is actually unclear. For example, if a transfer-trip channel is carried on a microwave path, an auditor may decide that the entire microwave equipment, microwave building battery, and microwave building emergency generator are all part of the Protection System, and thus subject to requirements in either PRC-005 or other existing or future Standards that refer to Protection System. AEP recommends that the term be phrased "communications paths" opposed to "communications systems". Similar to the above two items, we are concerned about the inclusion of voltage and current-sensing "devices" in the Definition. As written, applicability can be inferred to the entire device and not merely its output quantities, not only for this Standard but any other that references a

Protection System. AEP recommends the phrase "circuitry from voltage and current-sensing devices providing inputs to protective relays" instead of "voltage and current-sensing devices providing inputs to protective relays."

My comment is related to the Implementation plan which will modify the PER-005. I am specifically concerned with changing in R3.1 “established operating guides or “protection systems” to mitigate IROL violations” to “established operating guides or “Protection Systems” to mitigate IROL violations”. This modification changes the intent of requirement PER-005 R3.1. The requirement was developed by the drafting team to address an Order 693 directive to require the use of simulators by reliability coordinators, transmission operators and balancing authorities that have operational control over a significant portion of load and generation. The System Personnel Training SDT felt that the use of the phrase “established IROLs or has established operating guides or protection systems to mitigate IROL violations” appropriately represents the impact of entities on the reliability of the BES. In the context of PER-005 R3.1, this specific language was used to broadly include anything that an entity utilizes to prevent an IROL which could be an “operating guide or a protection system” like a RAS in WECC or an SPS in the Eastern Interconnection. It was not intended to include all the items included in the term that is being defined in Project 2007-17.

The drafting team did not properly address previous comments to include BES references in each PRC-005 sub bullet definitions and left "DC system" wording in the definition with only a comment in parentheses. The Protection System definition affects multiple standards and must stand alone across those standards. Therefore: 1. BES references are still needed in each sub bullet definition to eliminate ambiguity and to create clearly auditable requirements, meeting a basic standards drafting principal being requested both by FERC and the industry. 2. "DC system" remains a wide open definition. Because regulators and auditors are auditing to "zero" defect requirements and imposing their own interpretations, only specific wording is acceptable. The term "DC system" needs to be replaced with explicit pieces of equipment such as "batteries, battery chargers, and AC / DC

converters". To be a credible audit process, both the auditor and audited entity must have a clear understanding of what is being audited. DC system can be interpreted in many ways by an entity or auditor and is not an acceptable term. Further, BES references are needed to create clear and auditable boundaries for this definition.
Group

Steve Rueckert
The definition is generally accepable. However, we believe that better language for the third bullet is as follows: DC supply sources affecting the "Protection System" (including station batteries, battery chargers, and non-battery-based dc supply), and... A definition of non-battery-based dc supply should be included to avoid confusion and we offer the following: The inverter or rectifier in the circuit, dependent upon how the end use quipment is designed. Uninterruptible power supply (UPS) such as on-line, line-interactive or standby that some of the protection system could be on. The intent of the suggestion would consider that the entire protection system has to operate in order to maintain the reliability of the BES. An example would be if the protective relay and associated communications were on a UPS system and the intended device to operate were on station batteries, this would be the best case scenario as the Micro processors relays and the newer associated communications do not like the voltage drop when the station switches to the station batteries, hence the use of UPS options. Micro processors relays do have internal battery backup to keep them up and running, though a maintenance task would have to be included to be sure that they are properly maintained and tested, so the UPS option is easier and has been “kind of” an industry standard in the past. In the end the UPS would have to be on a maintenance schedule also.

While we agree with the definition itself, we do have a concern about its application. An ongoing issue that needs to be addressed is clarification of when a Bulk Electric System transmission Protection System applies to a Distribution Provider. This was addressed in part in the interpretation request regarding transmission Protection Systems, Project 2009-17. An example would be for a tee-tap off a Bulk Power System 345kV line to a step down transformer supplying distribution -- would the relaying on the low voltage side of the transformer be expected to comply with the requirements of PRC-005-2? Would the protection system configuration be considered a Protection System? Will this issue be addressed within the scope of Project 2007-17?

We have an issue with the implementation plan. The implementation plan proposes to capitalize the term "protection system" in NUC-001-2, PER-005-1, and PRC-001-1. We disagree with capatilizing the term because protection system was a defined term when these standards were written. Thus, if the drafting teams of those standards intended for the definition in the NERC glossary of terms to apply, they would have capatilized the term. Furthermore, capitalizing the term may fundamentally alter the meaning of the standard. For PER-005-1, we believe the standard is altered because protection system as used in this standard actually refers to special protection system or remedial action schemes.
Individual
Greg Rowland
Duke Energy

Yes
We agree with the revised definition. However the added language raises a question regarding how PRC-005-2 would be applied to DC supply situations where the battery is the backup to the “normal” source of DC power. Specifically, it’s unclear to us that Uninterruptible Power Supplies (UPS), rectifiers and motor-generator sets that use batteries as a backup are included in the scope of Table 1.
Individual
Alice Murdock Ireland
Xcel Energy
Yes
The Implementation Plan indicates that the lower case “protection system” in 3 other standards would be replaced with the capitalized term “Protection System” to properly reflect its use in those standards. In PRC-001 the term “protective system” is also used, however the Implementation Plan does not indicate whether this term will also be replaced. If not, then it would seem to imply that the term “protective system” has different meaning than “protection system/Protection System”. There is concern that the use of “Protection System” in PRC-001 will require entities to ‘coordinate” changes to all elements of the Protection System, which could be of no value for elements such as batteries, battery chargers. It is not clear as to if the intent that ALL elements of the Protection System be coordinated when a new or changed Protection System occurs.

The phrase, "non-battery-based dc supply" is ambigous and not well defined. It is critical this definition be clear in its intent and not introduce confusion to allow maintenance programs to be effective. Recommend this phrase either needs additional definition or should be considered for removal.

Consideration of Comments on Third Ballot — Project 2007-17 Protection System Maintenance (Protection System definition)

Dates of Third Ballot: 10/2/10 - 10/14/10

Summary: A successive ballot of the definition of Protection System was conducted from October 2-14, 2010 and achieved a quorum and an overall weighted segment approval of 84.52%.

Numerous balloters confused the definition with its applicability in various standards. Several balloters questioned the applicability of this defined term in PER-005 and the SDT modified the Implementation Plan for the definition to remove the reference to PER-005.

Several balloters used the ballot period as a forum to show displeasure with the NERC and Regional BES definitions. Modifying the definition of Bulk Electric System is outside the scope of this drafting team.

Some balloters made suggestions to modify various portions of the definition, however most balloters supported the definition as posted and the drafting team did not adopt any suggestions for further modifications to the definition.

Several balloters opposed this ballot because they felt the definition of Protection System should not have been balloted separately from the draft standard PRC-005-2. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT directed that the revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan allows entities at least 12 months to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.

If this has to be done faster than the pace of the current PRC-005-2 project, we suggest it still be paired with that project, but a smaller scope be considered to allow for this to pass quickly as possible and then the remaining work can be accomplished in PRC-005-3. 2. We suggest that the SDT consider the creation of sub-definitions opposed to crafting a single term for complex and diverse components that could make up the Protection System. As it stands, AEP cannot support this as it still does not remove the degree of ambiguity that could result in interpretation challenges during later enforcement and monitoring activities. We understand the urgency to make progress; however, the deliverables of this team can have significant collateral impacts in the compliance process. 3. The bullet for Protective relays should be further clarified with the addition of applied on or designed to provide protection for the BES that responds to the electrical fault or disturbance conditions. 4. Below are the comments that were provided in the second draft that were not adequately addressed in the consideration of the comments. A. The definition as drafted includes "Station dc supply." While this appears reasonable and innocuous, the term is unclear and could be construed by an auditor to include a lot of equipment and infrastructure not intended by the PSMT SDT. For example, station battery chargers are typically supplied by station auxiliary power transformers, which in turn are supplied by primary-voltage bus work, primary-voltage fuses, or primary-voltage circuit breakers. An auditor for either PRC-005 or any other Standard referencing "Protection System" could read that such primary-voltage equipment is part of the Protection System and therefore subject to certain requirements in either PRC-005 or any other Standard referencing Protection System. B. The definition as drafted includes "Communications systems necessary. . . ". Once again, this term appears innocuous, but it is

Segment	Entity	Member	Ballot	Comments
				actually unclear. For example, if a transfer-trip channel is carried on a microwave path, an auditor may decide that the entire microwave equipment, microwave building battery, and microwave building emergency generator are all part of the Protection System, and thus subject to requirements in either PRC-005 or other existing or future Standards that refer to Protection System. AEP recommends that the term be phrased "communications paths" opposed to "communications systems". C. Similar to the above two items, we are concerned about the inclusion of voltage and current-sensing "devices" in the Definition. As written, applicability can be inferred to the entire device and not merely its output quantities, not only for this Standard but any other that references a Protection System. AEP recommends the phrase "circuitry from voltage and current-sensing devices providing inputs to protective relays" instead of "voltage and current-sensing devices providing inputs to protective relays."

Response: When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.

2. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry.

3. The SDT believes these questions are not within the scope of Project 2007-17 and should be addressed by the Regional Entities.

4A. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry. The definition of Protection System with regards to dc supply has been modified and now reads: Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply).

4B. The SDT believes your comment pertains to standards and requirements, and not the definition of Protection System.

4C. The SDT believes the current draft of the definition as balloted is better supported by industry.

Segment	Entity	Member	Ballot	Comments
1	Baltimore Gas & Electric Company	John J. Moraski	Negative	The definition can be read to imply an obligation to test PTs and CTs in a way that exceeds the apparent intention of the SDT as expressed in the FAQs. The definition should be constructed so as to present no conflict with idea that the standard can be met by verifying the correctness of signal delivered from PTs and CTs to protective relays. Suggestive language included with the previous ballot --- Protection System: Protective relays which respond to electrical quantities, communication systems necessary for correct operation of protective functions, voltage and current sensing device output circuits and the associated circuits to the inputs of protective relays, station dc supply, and control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.
Response: The SDT believes your comment is aimed at revising the definition so that it achieves a particular outcome when applied to specific requirements in the proposed PRC-005. The team is trying to develop a definition that would be applicable for use in several standards, and does not want to make modifications to the definition that would limit the term's applicability.				
1	Colorado Springs Utilities	Paul Morland	Negative	CSU feels that battery chargers should not be included in the "Protection System" definition based on the following: Battery chargers are not a single point of immediate failure. As long as real-time station battery monitoring is provided, a reliable protection system will be maintained.
Response: When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" not including battery chargers, and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.				
1 3 6	FirstEnergy Energy Delivery FirstEnergy Solutions FirstEnergy Solutions	Robert Martinko Kevin Querry Mark S Travaglianti	Affirmative	FirstEnergy supports the definition and thanks the drafting team for incorporating our suggestion for clarification of the phrase "station dc supply".

Response: The SDT appreciates your support.				
1	MidAmerican Energy Co.	Terry Harbour	Negative	The drafting team did not properly address previous comments to include BES references in each PRC-005 sub bullet definitions and left "DC system" wording in the definition with only a comment in parentheses. The Protection System definition affects multiple standards and must stand alone across those standards. Therefore: 1. BES references are still needed in each sub bullet definition to eliminate ambiguity and to create clearly auditable requirements, meeting a basic standards drafting principal being requested both by FERC and the industry. 2. "DC system" remains a wide open definition. Because regulators and auditors are auditing to "zero" defect requirements and imposing their own interpretations, only specific wording is acceptable. The term "DC system" needs to be replaced with explicit pieces of equipment such as "batteries, battery chargers, and AC / DC converters". To be a credible audit process, both the auditor and audited entity must have a clear understanding of what is being audited. DC system can be interpreted in many ways by an entity or auditor and is not an acceptable term. Further, BES references are needed to create clear and auditable boundaries for this definition.
Response: The SDT believes your comment is aimed at revising the definition so that it achieves a particular outcome when applied to specific requirements in the proposed PRC-005. The team is trying to develop a definition that would be applicable for use in several standards, and does not want to make modifications to the definition that would limit the term's applicability.				

Segment	Entity	Member	Ballot	Comments
1	Nebraska Public Power District	Richard L. Koch	Affirmative	1. Please provide the reasoning for including the battery chargers. Where do you draw the line of what is included. For example, should the panel providing power to the chargers be included? 2. Better clarification is needed when defining the DC control circuit. The trip coils are identified on one end of the circuit but nothing is identified upstream of the trip coils. For example, control switches, indicators, auxiliary relays, power supply breakers, etc.
Response: 1. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" not including battery chargers, and directed that work to close this reliability gap should be given “priority.” The definition of Protection System with regards to dc supply has been modified and now reads: Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply). The SDT believes this clearly limits the dc supply. 2. The SDT believes the balloted definition includes all the control circuitry essential for the Protection System to function properly.				
1	Pacific Gas and Electric Company	Chifong L. Thomas	Negative	We disagree with the drafting team response to comments that the term BES should be included only in the standard. It is an essential part of the definition as it pertains to the purpose of NERC Standards. As a result we have changed our vote to negative. We view the basic intent of this definition is to identify what protective systems in facilities are to be utilized to protect the BES from two primary troubles 1) minimize interruption of the flow of electrical power from one portion of the BES to another, and 2) to prevent the propagation of BES trouble from one portion of the BES to another. While we agree that protection systems for all transmission related components can be adequately limited in scope by utilizing "electrical quantities", we do not feel that it is adequate for generating facilities. There are multitudes of elements in generating facilities that can remove the facility from service and impact the power flow from the facility to other portions of the BES. The efforts utilized thus far demonstrate that it is not desirable or realistically possible to address all devices from an oversight point of view and that the current definition which discriminates solely with the qualifier of "electrical quantities" is too broad and leaves much open to interpretation to define what types of protection are included in the definition. The definition, as it currently reads, leaves many protective devices to the owner/operator to manage for

Segment	Entity	Member	Ballot	Comments
				maximum reliability of the generating facility. In the interest of clarity the definition should limit the scope for protective relays to those relays designed to prevent the propagation of trouble from one portion of the BES to another. We recommend changing the proposed definition to read as follows: A control system designed to detect electrical faults or abnormal conditions in the power system and initiate corrective action(s). A protection system consists of the following components: 1. Protective relays which protect: a) Transmission BES elements, including generating facility step up transformers, and respond to power system electrical quantities such as voltage and current, b) Generating facilities by responding to power system electrical quantities, such as voltage and current, and are designed to protect against potential problems in the BES on the high side of the generator step up transformer. 2. Communications systems necessary for correct operation of protective functions, 3. Voltage and current sensing devices which transform high level power system quantities to low level inputs for protective relays, and the associated circuitry to the inputs for protective relays. 4. Station DC supply associated with protective relay power supplies and control functions (including station batteries, battery chargers, and non-battery-based DC supply), and 5. Control circuitry associated with protective relay functions (including auxiliary relays) through the trip coil(s) of the circuit breakers or other interrupting devices.
Response: The SDT believes your comment is aimed at revising the definition so that it achieves a particular outcome when applied to specific requirements in the proposed PRC-005. The team is trying to develop a definition that would be applicable for use in several standards, and does not want to make modifications to the definition that would limit the term's applicability. The applicability of the definition of Protection System will be addressed in the various standards which utilize the definition. The SDT believes the current draft of the definition as balloted is better supported by industry.				
1 3 4 5	Seattle City Light	Pawel Krupa Dana Wheelock Hao Li Michael J. Haynes	Affirmative	Seattle supports this definition with the understanding that issues that have been previously addressed through comment will be considered during the Standard development process.

Segment	Entity	Member	Ballot	Comments
6		Dennis Sismaet		
Response: The SDT appreciates your support.				
1 3	Tri-State G & T Association, Inc.	Keith V. Carman Janelle Marriott	Negative	2nd bullet - Add communication-aided before protective functions. We think that this is important because you can have correct operation of protective functions without the communication-aided tripping functions operating correctly, especially with POTT or DCUB schemes. 5th bullet - replace through with including. We think that the phrase through the trip coil could be misinterpreted to mean protective functions that cause current to flow through the trip coil rather than the inclusive meaning such as from A through Z. If the intent of the drafting team is to exclude the trip coil, then we think it should be changed to control circuitry associated with protective functions required to operate the trip coil(s) of the circuit breakers or other interrupting devices.
Response: The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry.				

Segment	Entity	Member	Ballot	Comments
1	Western Area Power Administration	Brandy A Dunn	Negative	The term "protection functions" is ambiguous as it is not related to the protection function associated with the protective relays. There are other protection functions not associated with protective relays that respond to electrical quantities. The language for Communication systems should be changed to remove the ambiguity. The following change would be clear, "Communication system necessary for the correct operation of the protective relays" The input to the relays is from voltage and current sensing devices through their respective circuits. Since the definition for protective relays separates the term "control circuitry" associated with protective relays, it is clear that protective relays do not also include the "control circuitry". By the same token, voltage and current sensing devices do not include their related circuits. The definition for voltage and current sensing devices should be revised to include the term "circuits". The following language change would serve make it clear: "Voltage and current sensing devices and their respective circuits providing inputs protective relays,".
5	U.S. Bureau of Reclamation	Martin Bauer P.E.	Negative	The term "protection functions" is ambiguous as it is not related to the protection function associated with the protective relays. There are other protection functions not associated with protective relays that respond to electrical quantities. The language for Communication systems should be changed to remove the ambiguity. The following change would be clear, "Communication system necessary for the correct operation of the protective relays" The input to the relays is from voltage and current sensing devices through their respective circuits. Since the definition for protective relays separates the term "control circuitry" associated with protective relays, it is clear that protective relays do not also include the "control circuitry". By the same token, voltage and current sensing devices do not include their related circuits. The definition for voltage and current sensing devices should be revised to include the term "circuits". The following language change would serve make it clear: "Voltage and current sensing devices and their respective circuits providing correct inputs to protective relays."

Segment	Entity	Member	Ballot	Comments
Response: The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry.				
2	Midwest ISO, Inc.	Jason L Marshall	Negative	We disagree with the implementation plan. The implementation plan calls for capitalizing protection system in NUC-001-2 and PER-005-1. Because Protection System had been included in the NERC Glossary of Terms before the development of these standards, we believe the drafting teams would have capitalized those terms in these standards if they had intended for the Protection System definition to apply. Furthermore, we believe the use of protection system PER-005-1 was actually intended to be special protection systems or remedial actions schemes. To capitalize protection system in PER-005-1 will fundamentally alter the requirement in which it is contained.
Response: The SDT agrees and will revise the Implementation Plan to remove PER-005 from the list of standards to be modified. However, the SDT believes the term Protection System should be capitalized as described in the Implementation Plan for NUC-001-2.				
3 4 5	Consumers Energy	David A. Lapinski David Frank Ronk James B Lewis	Negative	We understand that this posting is intended to address perceived flaws in the currently approved definition. However, since this change, if approved, is likely to result in changes to an entity's PRC-005-1 maintenance program, we feel that it is inappropriate to approve this definition without simultaneous approval of the revised PRC-005-2 which will clarify the related changes to maintenance programs.
Response: When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" not including battery chargers, and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.				
3	MidAmerican Energy Co.	Thomas C. Mielnik	Negative	BES references are needed in each sub bullet definition to eliminate ambiguity and to create clearly auditable requirements. The term "DC system" needs to be replaced with explicit pieces of equipment such as "batteries, battery chargers, and AC / DC converters".
Response: The SDT believes these comments relative to BES are not within the scope of Project 2007-17 and should be addressed by the Regional Entities; and that the current draft of the definition as balloted is clear, concise, and contains the specific dc systems equipment you mention.

4	Madison Gas and Electric Co.	Joseph G. DePoorter	Affirmative	Believe that Communication systems necessary for correct operation of protective "relay" functions be considered as an enhancement to the definition. This would also need to be added within the Station dc supply and Control circuitry bullets. This will provide clarity to exactly what the definition is describing.
Response: The SDT appreciates your support. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry.				
5	Constellation Power Source Generation, Inc.	Amir Y Hammad	Negative	Constellation has previously voted against these revised definitions because as written, it implies that the testing of PTs and CTs in PRC-005 is required. This latest proposal is no different. Constellation agrees with the SDT in that current and voltage sensing devices are an important aspect of the Protection System. However, by including PTs and CTs in the definition, auditors have been interpreting that as stating that dielectric testing and other tests are necessary on them. This does not seem to be the intention of the SDT. The intention of the SDT seems to be to verify that the sensing devices are delivering acceptable signals to relays. Table 1 a of the PRC-005-2 standard includes: Voltage & Current Sensing Devices / 12 Calendar Years / Verify proper functioning of the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays. The FAQ for PRC-005-2 is even clearer in stating that ensuring the protection system is receiving the expected values from current and voltage sensing devices. But neither the originally revised or newly revised definitions carry that implication very well. The definitions are still including the devices themselves and not their outputs. To make the definition less ambiguous with PTs and CTs, Constellation proposes the following change in the definition: Voltage and current sensing devices providing inputs to protective relays to; Voltage and current sensing device output circuits and the associated circuits to the inputs of protective relays.

Segment	Entity	Member	Ballot	Comments
6	Constellation Energy Commodities Group	Brenda Powell	Negative	Constellation has previously voted against these revised definitions because as written, it implies that the testing of PTs and CTs in PRC-005 is required. This latest proposal is no different. Constellation agrees with the SDT in that current and voltage sensing devices are an important aspect of the Protection System. However, by including PTs and CTs in the definition, auditors have been interpreting that as stating that dielectric testing and other tests are necessary on them. This does not seem to be the intention of the SDT. The intention of the SDT seems to be to verify that the sensing devices are delivering acceptable signals to relays. The definitions are still including the devices themselves and not their outputs. To make the definition less ambiguous with PTs and CTs, Constellation proposes the following change in the definition: Voltage and current sensing devices providing inputs to protective relays to; Voltage and current sensing device output circuits and the associated circuits to the inputs of protective relays.
Response: The SDT believes your comment is aimed at revising the definition so that it achieves a particular outcome when applied to specific requirements in the proposed PRC-005. The team is trying to develop a definition that would be applicable for use in several standards, and does not want to make modifications to the definition that would limit the term's applicability.				
5	Dynegy Inc.	Dan Roethemeyer	Affirmative	Please clarify "non-battery-based dc supply". It is vague.
Response: The SDT appreciates your support, and believes the current draft of the definition as balloted is clear, concise, and supported by industry. The term “non-battery-based dc supply” is meant to be a broad term to capture other methods such as flywheels, compressed air, fuel cells, or any other emerging technology which is capable of supplying dc power to the Protection System.				

Segment	Entity	Member	Ballot	Comments
5	Indeck Energy Services, Inc.	Rex A Roehl	Negative	Neither batteries nor battery chargers are part of protection systems. They may be included in protection system maintenance procedures, but are not part of a protection system. Similarly, current and voltage measuring devices that are used for metering or monitoring and not exclusively for protection, are not part of the protection system, but may be included in protection system maintenance. THE SDT seems to have tried to incorporate some of the PRC standards with this definition rather than focusing on the one element being defined.
Response: When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" not including battery chargers, and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now.				
5	Liberty Electric Power LLC	Daniel Duff	Negative	Battery chargers are not protection system elements. This part of the definition should be redacted.
Response: When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" not including battery chargers, and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now.				
5	Public Utility District No. 1 of Lewis County	Steven Grega	Negative	Do not support the expanded definition of the protection system. Battery chargers are not part of the protection system.
Response: : When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" not including battery chargers, and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now.				

Segment	Entity	Member	Ballot	Comments
5 6	RRI Energy	Thomas J. Bradish Trent Carlson	Negative	It is not appropriate to define the battery or chargers as protection system elements. For DC circuits or supply, the definition and subsequent boundary of the protection system should end at the fuses or circuit breakers of the sources supplying the individual DC control circuits of the protection system. For a typical power plant station battery, the percent of the battery capacity sized for the protection system is very small. The battery and chargers are power source elements, not protection elements. Likewise, all intermediate power distribution elements between the battery, chargers, and dedicated protection system branch circuits, do not belong in the definition of the Protection System.
Response: : When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" not including battery chargers, and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now.				
5	TransAlta Centralia Generation, LLC	Joanna Luong-Tran	Negative	To increase the clarity of the definition, TransAlta proposes the following: Control circuitry associated with protective functions through to and including the trip coil(s) of the circuit breakers or other interrupting devices
Response: The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry.				

Segment	Entity	Member	Ballot	Comments
8	SPS Consulting Group Inc.	Jim R Stanton	Negative	The term "Communication System" remains in the definition, despite the reality that at least for most generators, there is no communication system within the Protection System. Communication from device to device, such as a protective relay to a trip coil or alarm, it not a "system" per se but merely a wire connecting the devices. Keeping this definition as is perpetuates the confusion of generators when they design, modify and execute their protection system maintenance and testing program as the definition of the Protection System requires addressing a "communication system" which they do not have. Keeping the definition as is could lead to confused auditors who insist on literal adherence to the requirement language, clouding the audit and imposing ad hoc and perhaps inconsistent interpretations for audits, spot checks and self reports. What will most surely happen if this definition is approved is a quick request for interpretation by one or more entities seeking clarification on the requirement to include "communication systems" within their maintenance and testing program when they in fact have no such system. All this can be avoided by changing the term "communication systems" to "communication components." This is a primary example of fixing something on the front end so we don't have to go through interpretations and revisions to fix an ambiguity. This definition would also not pass a Quality Review due to the ambiguity of terms.
Response: The SDT believes the language is clear and addresses relay communication systems currently used by industry.				
8	Utility Services, Inc.	Brian Evans-Mongeon	Negative	While the language by itself is supportable, the definition is not complete. The SDT has still not addressed the question of when the definition will apply to Distribution Providers. Many DPs own and or operate the elements listed in the definition; however, the definition lacks clarity when such ownership or operation is subject to the performance obligations under the standard.
Response: This clarification is provided in each requirement that uses the term, “Protection System” by identifying the responsible entity. The comment relates to "application" of the definition, not to the definition.				

Segment	Entity	Member	Ballot	Comments
9	California Energy Commission	William Mitchell Chamberlain	Affirmative	The proposed definition is generally acceptable. However, a slight modification to the third bullet in the definition would be an improvement to the proposed wording: "DC supply sources affecting the 'Protection System' (including station batteries, battery chargers, and non-battery-based dc supply), and " In addition, a definition of non-battery-based dc supply should be included to avoid confusion we recommend the following: "The inverter or rectifier in the circuit, dependent upon how the end use equipment is designed. Uninterruptible power supply (UPS) such as on-line, line-interactive or standby that some of the protection system could be on."
Response: The SDT appreciates your support. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry. The term "non-battery-based dc supply" is meant to be a broad term to capture other methods such as flywheels, compressed air, fuel cells, or any other emerging technology which is capable of supplying dc power to the Protection System.				
9	Oregon Public Utility Commission	Jerome Murray	Affirmative	Although I voted yes, I recommend the following proposed wording for the third bullet: DC supply sources affecting the "Protection System" (including station batteries, battery chargers, and non-battery-based dc supply), and Also the definition of non-battery-based dc supply should be included to avoid confusion. I recommend the following: The inverter or rectifier in the circuit, dependent upon how the end use equipment is designed. Uninterruptible power supply (UPS) such as on-line, line-interactive or standby that some of the protection system could be on.
Response: The SDT appreciates your support. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry. The term "non-battery-based dc supply" is meant to be a broad term to capture other methods such as flywheels, compressed air, fuel cells, or any other emerging technology which is capable of supplying dc power to the Protection System.				
10	Midwest Reliability Organization	Dan R. Schoenecker	Affirmative	Suggest the second bullet language replace the term correct with the intended. Communications systems necessary for the intended operation of protective functions.
Response: The SDT appreciates your support. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry.				

Segment	Entity	Member	Ballot	Comments
10	Western Electricity Coordinating Council	Louise McCarren	Affirmative	The definition is generally acceptable. However, we believe that better language for the third bullet is as follows: DC supply sources affecting the "Protection System" (including station batteries, battery chargers, and non-battery-based dc supply), and A definition of non-battery-based dc supply should be included to avoid confusion and we offer the following: The inverter or rectifier in the circuit, dependent upon how the end use equipment is designed. Uninterruptible power supply (UPS) such as on-line, line-interactive or standby that some of the protection system could be on. The intent of the suggestion would consider that the entire protection system has to operate in order to maintain the reliability of the BES. An example would be if the protective relay and associated communications were on a UPS system and the intended device to operate were on station batteries, this would be the best case scenario as the Micro processors relays and the newer associated communications do not like the voltage drop when the station switches to the station batteries, hence the use of UPS options. Micro processors relays do have internal battery backup to keep them up and running, though a maintenance task would have to be included to be sure that they are properly maintained and tested, so the UPS option is easier and has been kind of an industry standard in the past. In the end the UPS would have to be on a maintenance schedule also.
Response: The SDT appreciates your support. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry. The term “non-battery-based dc supply” is meant to be a broad term to capture other methods such as flywheels, compressed air, fuel cells, or any other emerging technology which is capable of supplying dc power to the Protection System.				

Consideration of Comments on Protection System Maintenance & Testing — Project 2007-17 – Definition of Protection System

The Protection System Maintenance & Testing Standard Drafting Team thanks all commenters who submitted comments for the revised definition of "Protection System."

The revised definition was posted for a 30-day public comment period from September 13, 2010 through October 12, 2010. Stakeholders were asked to provide feedback on the definition through a special Electronic Comment Form. There were 27 sets of comments, including comments from more than 62 different people from approximately 53 companies representing 7 of the 10 Industry Segments as shown in the table on the following pages.

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

While several commenters made suggestions to further refine the definition of Protection System, the team did not make any additional changes to the definition based on stakeholder comments. The team did, however remove the proposed modification to PER-005 from the implementation plan. No other changes were made.

- Some commenters made suggestions for modifications to various portions of the proposed definition of Protection System. There was no commonality to the proposed revisions and these modifications did not seem to provide greater clarity than was provided with the last version of the proposed definition posted for comment and ballot. Since most stakeholders agreed with the latest version of the proposed definition, no changes were made to the definition.
- Several commenters questioned the applicability of the defined term "Protection System" in PER-005; the SDT agreed and modified the Implementation Plan for the definition of Protection System to remove the reference to PER-005.
- Several commenters also used the comment period as a forum to show displeasure with the NERC and regional BES definitions. Making modifications to the definition of BES is outside the scope of work assigned to this drafting team.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 609-452-8060 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

1. **Do you agree with the proposed definition of "Protection System?" If not, please provide specific suggestions for improvement.**

Summary Consideration: Numerous commenters confused the definition with its applicability in various standards. Other commenters made suggestions to modify various portions of the definition. No changes were made to the definition in response to these comments. Several commenters questioned the applicability of the defined term "Protection System" in PER-005; the SDT agreed and modified the Implementation Plan for the definition of Protection System to remove the reference to PER-005. Several commenters also used the comment period as a forum to show displeasure with the NERC and regional BES definitions. Making changes to the definition of Bulk Electric System is outside the scope of work assigned to this drafting team.

Organization	Yes or No	Question 1 Comment
NERC Staff	No	NERC staff does not support the phrase "voltage and current sensing devices providing input to protective relays." While no version of the definition has been all-inclusive with respect to this phrase, we believe that the best phrase would be a combination of several drafts and should state the following: "voltage and current sensing devices and associated circuitry from the voltage and current sensing devices to the protective relay inputs." As currently written, the definition represents a step backward from the language in the previous definition ("voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices") and should be modified.
Response: Thank you for your comment. The SDT believes the current draft of the definition as balloted is better supported by industry.		
Northeast Power Coordinating Council	No	This project addresses the definition of a Protection System. However, an ongoing issue that needs to be addressed is clarification of when a Bulk Electric System transmission Protection System applies to a Distribution Provider. An example would be for a tee-tap off a Bulk Power System 345kV line to a step down transformer supplying distribution--would the relaying on the low side of the transformer be expected to comply with the requirements of PRC-005-2? Would the protection system configuration be considered a Protection System? Will this issue be addressed within the scope of Project 2007-17?
Response: Thank you for your comment. The SDT believes these questions are not within the scope of Project 2007-17 and should be addressed by the Regional Entities.		
WECC		The definition is generally acceptable. However, we believe that better language for the third bullet is as follows: DC supply sources affecting the "Protection System" (including station batteries, battery chargers, and non-battery-based dc supply), and...A definition of non-battery-based dc supply should be included to avoid confusion and we offer the following: The inverter or rectifier in the circuit, dependent upon how the end use quipment is designed. Uninterruptible power supply (UPS) such as on-line, line-interactive or standby that some of the protection system could be on. The intent of the suggestion would consider that the entire protection system has to operate in order to maintain the reliability of the BES. An example would be if the protective relay

Organization	Yes or No	Question 1 Comment
		and associated communications were on a UPS system and the intended device to operate were on station batteries, this would be the best case scenario as the Micro processors relays and the newer associated communications do not like the voltage drop when the station switches to the station batteries, hence the use of UPS options. Micro processors relays do have internal battery backup to keep them up and running, though a maintenance task would have to be included to be sure that they are properly maintained and tested, so the UPS option is easier and has been "kind of" an industry standard in the past. In the end the UPS would have to be on a maintenance schedule also.
Response: Thank you for your comment. The SDT believes the current draft of the definition as balloted is better supported by industry. The term "non-battery-based dc supply" is meant to be a broad term to capture other methods such as flywheels, compressed air, fuel cells, or any other emerging technology which is capable of supplying dc power to the Protection System.		
Kansas City Power & Light	No	The phrase, "non-battery-based dc supply" is ambiguous and not well defined. It is critical this definition be clear in its intent and not introduce confusion to allow maintenance programs to be effective. Recommend this phrase either needs additional definition or should be considered for removal.
Response: Thank you for your comment. The SDT believes the language is clear and supported by industry. The term "non-battery-based dc supply" is meant to be a broad term to capture other methods such as flywheels, compressed air, fuel cells, or any other emerging technology which is capable of supplying dc power to the Protection System.		
SPS Consulting Group Inc.	No	The revised definition perpetuates the confusion over "communications systems" embedded or otherwise associated with Protection Systems. The term "communications components" is more accurate.
Response: Thank you for your comment. The SDT believes the language is clear and addresses relay communication systems currently used by industry.		
US Bureau of Reclamation	No	The term "protection functions" is ambiguous as it is not related to the protection function associated with the protective relays. There are other protection functions not associated with protective relays that respond to electrical quantities. The language for Communication systems should be changed to remove the ambiguity. The following change would be clear, "Communication system necessary for the correct operation of the protective relays" The input to the relays is from voltage and current sensing devices through their respective circuits. Since the definition for protective relays separates the term "control circuitry" associated with protective relays, it is clear that protective relays do not also include the "control circuitry". By the same token, voltage and current sensing devices do not include their related circuits. The definition for voltage and current sensing devices should be revised to include the term "circuits". The following language change would serve make it clear: "Voltage and current sensing devices and their respective circuits providing inputs protective relays".
Response: Thank you for your comment. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry.		
US Army Corps of Engineers	No	The use of the term "protection functions" is not a defined NERC term and either the term should be defined or it should not be used. At best the term is ambiguous and could lead to scope growth by auditors. Recommend

Organization	Yes or No	Question 1 Comment
		that the following changes be made: "Communication system necessary for the correct operation of the protective relays." "Control circuitry associated with protective relays through the trip coil(s) of the circuit breaker or other interrupting device." See the next paragraph for the proposed correction to the DC Supply part of the definition. The input to the relay is from voltage and current sensing devices yet there is no mention of the associated circuits. The same can be said about the station DC supply circuits. The definition should apply to the circuits providing inputs or control power to the protective relays and from the output of the relays to the tripping coils of the circuit breaker. Recommend the following: "Voltage and current sensing devices and their respective circuits providing inputs to the protective relays." "Station DC supply associated with protective relays (including station batteries, battery charger, non-battery-based DC supply circuitry to the protective relays and from the relay to the trip coil(s)of the circuit breaker), and"
Response: Thank you for your comment. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry.		
Dynegy Inc.	No	The majority of the definition is good; however, the term "non-battery-based dc supply' is still somewhat vague. Can you please further define or provide some examples?
Response: Thank you for your comment. The SDT believes the language is clear and supported by industry. The term “non-battery-based dc supply” is meant to be a broad term to capture other methods such as flywheels, compressed air, fuel cells, or any other emerging technology which is capable of supplying dc power to the Protection System.		
CenterPoint Energy	No	(a) CenterPoint Energy believes the proposed re-definition of “Protection System” is technically incorrect due to the inclusion of trip coils as part of the control circuitry. A protection system has correctly performed its function if it provides tripping voltage up to the terminals of trip coils. From that point, the circuit breaker can fail to timely interrupt fault current due to several factors, such as a binding mechanism, stuck mechanism, broken pull rod, bad insulating medium, or bad trip coils. Local breaker failure protection, or remote backup protection, is installed to address the various possible causes of circuit breaker failure. The proposed re-definition of “Protection System” should be revised to indicate control circuitry associated with protective functions UP TO THE TERMINALS OF the trip coil(s) of the circuit breakers or other interrupting devices. (b) On the surface, the proposed re-definition of “Protection System” appears mainly applicable to PRC-005 based upon the Standards Announcement and proposed Implementation Plan. However, NERC standard PRC-004-1 Analysis and Mitigation of Transmission and Generation Protection System Misoperations also uses the capitalized term “Protection System”. CenterPoint Energy believes it is inappropriate to require reporting of Misoperations of transmission Protection Systems and generator Protection Systems for bad trip coils within a circuit breaker. For application to PRC-004-1, CenterPoint Energy recommends revising the proposed re-definition to indicate control circuitry associated with protective functions UP TO THE TERMINALS OF the trip coil(s) of the circuit breakers or other interrupting devices.
Response: Thank you for your comment. The SDT believes the current draft of the definition as balloted is better supported by industry.		
Midwest ISO	No	We have an issue with the implementation plan. The implementation plan proposes to capitalize the term

Organization	Yes or No	Question 1 Comment
		"protection system" in NUC-001-2, PER-005-1, and PRC-001-1. We disagree with capitalizing the term because protection system was a defined term when these standards were written. Thus, if the drafting teams of those standards intended for the definition in the NERC glossary of terms to apply, they would have capitalized the term. Furthermore, capitalizing the term may fundamentally alter the meaning of the standard. For PER-005-1, we believe the standard is altered because protection system as used in this standard actually refers to special protection system or remedial action schemes.
Response: Thank you for your comment. The SDT agrees and will revise the Implementation Plan to remove PER-005 from the list of standards to be modified. However, the SDT believes the term Protection System should be capitalized as described in the Implementation Plan for NUC-001-2 and PRC-001-1.		
American Electric Power (AEP)	No	1. This change in definition needs to occur concurrently with other related projects (PRC-005-2). Neither the SDT nor the SC should establish a practice of making changes to definitions outside the parameters of changes to standards. This will introduce opportunities for confusion and does not provide the appropriate signals to the Registered Entities to adjust their programs and make the appropriate changes. If this has to be done faster than the pace of the current PRC-005-2 project, we suggest it still be paired with that project, but a smaller scope be considered to allow for this to pass quickly as possible and then the remaining work can be accomplished in PRC-005-3. 2. We suggest that the SDT consider the creation of sub-definitions opposed to crafting a single term for complex and diverse components that could make up the Protection System. As it stands, AEP cannot support this as it still does not remove the degree of ambiguity that could result in interpretation challenges during later enforcement and monitoring activities. We understand the urgency to make progress; however, the deliverables of this team can have significant collateral impacts in the compliance process. 3. The bullet for Protective relays should be further clarified with the addition of applied on or designed to provide protection for the BES that responds to the electrical fault or disturbance conditions. 4. Below are the comments that were provided in the second draft that were not adequately addressed in the consideration of the comments. A. The definition as drafted includes "Station dc supply." While this appears reasonable and innocuous, the term is unclear and could be construed by an auditor to include a lot of equipment and infrastructure not intended by the PSMT SDT. For example, station battery chargers are typically supplied by station auxiliary power transformers, which in turn are supplied by primary-voltage bus work, primary-voltage fuses, or primary-voltage circuit breakers. An auditor for either PRC-005 or any other Standard referencing "Protection System" could read that such primary-voltage equipment is part of the Protection System and therefore subject to certain requirements in either PRC-005 or any other Standard referencing Protection System. B. The definition as drafted includes "Communications systems necessary. . . ". Once again, this term appears innocuous, but it is actually unclear. For example, if a transfer-trip channel is carried on a microwave path, an auditor may decide that the entire microwave equipment, microwave building battery, and microwave building emergency generator are all part of the Protection System, and thus subject to requirements in either PRC-005 or other existing or future Standards that refer to Protection System. AEP

Organization	Yes or No	Question 1 Comment
		recommends that the term be phrased "communications paths" opposed to "communications systems". C. Similar to the above two items, we are concerned about the inclusion of voltage and current-sensing "devices" in the Definition. As written, applicability can be inferred to the entire device and not merely its output quantities, not only for this Standard but any other that references a Protection System. AEP recommends the phrase "circuitry from voltage and current-sensing devices providing inputs to protective relays" instead of "voltage and current-sensing devices providing inputs to protective relays."
Response: When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1. **2. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry.** **3. The SDT believes these questions are not within the scope of Project 2007-17 and should be addressed by the Regional Entities.** **4A. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry. The definition of Protection System with regards to dc supply has been modified and now reads:** Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply). **4B. The SDT believes your comment pertains to standards and requirements, and not the definition of Protection System.** **4C. The SDT believes the current draft of the definition as balloted is better supported by industry.**		
Independent Electricity System Operator	No	While we agree with the definition itself, we do have a concern about its application. An ongoing issue that needs to be addressed is clarification of when a Bulk Electric System transmission Protection System applies to a Distribution Provider. This was addressed in part in the interpretation request regarding transmission Protection Systems, Project 2009-17. An example would be for a tee-tap off a Bulk Power System 345kV line to a step down transformer supplying distribution -- would the relaying on the low voltage side of the transformer be expected to comply with the requirements of PRC-005-2? Would the protection system configuration be considered a Protection System? Will this issue be addressed within the scope of Project 2007-17?
Response: Thank you for your comment. This clarification is provided in each requirement that uses the term, "Protection System" by identifying the responsible entity. The question relates to "application" of the definition, not to the definition."		
NRECA		My comment is related to the Implementation plan which will modify the PER-005. I am specifically concerned with changing in R3.1 "established operating guides or "protection systems" to mitigate IROL violations" to "established operating guides or "Protection Systems" to mitigate IROL violations". This modification changes the intent of requirement PER-005 R3.1. The requirement was developed by the drafting team to address an Order 693 directive to require the use of simulators by reliability coordinators, transmission operators and balancing authorities that have operational control over a significant portion of load and generation. The System Personnel Training SDT felt that the use of the phrase "established IROLs or has established operating guides

Organization	Yes or No	Question 1 Comment
		or protection systems to mitigate IROL violations" appropriately represents the impact of entities on the reliability of the BES. In the context of PER-005 R3.1, this specific language was used to broadly include anything that an entity utilizes to prevent an IROL which could be an "operating guide or a protection system" like a RAS in WECC or an SPS in the Eastern Interconnection. It was not intended to include all the items included in the term that is being defined in Project 2007-17.
Response: Thank you for your comment. The SDT agrees and will revise the Implementation Plan to remove PER-005 from the list of standards to be modified.		
MidAmerican Energy	No	The drafting team did not properly address previous comments to include BES references in each PRC-005 sub bullet definitions and left "DC system" wording in the definition with only a comment in parentheses. The Protection System definition affects multiple standards and must stand alone across those standards. Therefore: 1. BES references are still needed in each sub bullet definition to eliminate ambiguity and to create clearly auditable requirements, meeting a basic standards drafting principal being requested both by FERC and the industry. 2. "DC system" remains a wide open definition. Because regulators and auditors are auditing to "zero" defect requirements and imposing their own interpretations, only specific wording is acceptable. The term "DC system" needs to be replaced with explicit pieces of equipment such as "batteries, battery chargers, and AC / DC converters". To be a credible audit process, both the auditor and audited entity must have a clear understanding of what is being audited. DC system can be interpreted in many ways by an entity or auditor and is not an acceptable term. Further, BES references are needed to create clear and auditable boundaries for this definition.
Response: Thank you for your comments. These comments all relate to "application" of the definition; "auditable boundaries" and "auditable requirements" are part of the standard.		
Duke Energy	Yes	We agree with the revised definition. However the added language raises a question regarding how PRC-005-2 would be applied to DC supply situations where the battery is the backup to the "normal" source of DC power. Specifically, it's unclear to us that Uninterruptible Power Supplies (UPS), rectifiers and motor-generator sets that use batteries as a backup are included in the scope of Table 1.
Response: Thank you for your comment. The SDT believes your comment pertains to the standard PRC-005-2 and not the definition of Protection Systems.		
Xcel Energy	Yes	The Implementation Plan indicates that the lower case "protection system" in 3 other standards would be replaced with the capitalized term "Protection System" to properly reflect its use in those standards. In PRC-001 the term "protective system" is also used, however the Implementation Plan does not indicate whether this term will also be replaced. If not, then it would seem to imply that the term "protective system" has different meaning than "protection system/Protection System". There is concern that the use of "Protection System" in PRC-001 will require entities to 'coordinate" changes to all elements of the Protection System, which could be of no value for elements such as batteries, battery chargers. It is not clear as to if the intent that ALL elements of the

Organization	Yes or No	Question 1 Comment
		Protection System be coordinated when a new or changed Protection System occurs.
Response: Thank you for your comment. The term "protective system" is not a defined term in the NERC glossary and is not addressed by the Implementation Plan.		
LIPA	Yes	Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and ....Change to Station dc supply associated with protective functions, and....
Response: Thank you for your comment. The SDT believes the current draft of the definition as balloted is better supported by industry.		
American Transmission Company	Yes	None.

Proposed Definition of Protection System:

Protection System –

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

Protection System Definition

The previously approved (Board of Trustees) definition of Protection System reads as follows:

Protection System: Protective relays, associated communication systems, voltage and current sensing devices, station batteries and DC control circuitry.

Proposed Changes to Board of Trustees Approved Version of Definition:

Protection System: Protective relays which respond to electrical quantities, ~~associated~~ communication systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays, station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery based ~~and DC~~ dc supply), and control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

Implementation Plan for the Revised Definition of Protection System

Prerequisite Approvals or Activities:

The implementation of the revised definition is not dependent upon any other activity.

Recommended Modifications to Already Approved Standards

The non-capitalized version of the term, “protection system” is used in the following approved standards:

- NUC-001-2 – Nuclear Plant Interface Coordination
- PRC-001-1 – System Protection Coordination

The term, “protection system” shall be capitalized where used in these standards when the definition of “Protection System” is approved by applicable regulatory authorities.

Proposed Effective Date:

Each responsible entity (Distribution Provider that owns a transmission Protection System, Transmission Owner, and Generator Owner) shall modify its protection system maintenance and testing program description and basis document(s) (required in Requirement R1 of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing) as necessary to reflect the modified definition of ‘Protection System’ by the first day of the first calendar quarter twelve months following regulatory approvals and implement any additional maintenance and testing (required in Requirement R2 of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing) by the end of the first complete maintenance and testing cycle described in the entity’s program description and basis document(s) following establishment of the program changes resulting from the revised definition.

The original definition of “Protection System” shall be retired at the same time the revised definition becomes effective.

Implementation Plan for the Revised Definition of Protection System

Prerequisite Approvals or Activities:

The implementation of the revised definition is not dependent upon any other activity.

Recommended Modifications to Already Approved Standards

The non-capitalized version of the term, "protection system" is used in the following approved standards:

- NUC-001-2 – Nuclear Plant Interface Coordination
- ~~PER-005-1 – System Personnel Training~~
- PRC-001-1 – System Protection Coordination

The term, "protection system" shall be capitalized where used in these standards when the definition of "Protection System" is approved by applicable regulatory authorities.

Proposed Effective Date:

Each responsible entity (Distribution Provider that owns a transmission Protection System, Transmission Owner, and Generator Owner) shall modify its protection system maintenance and testing program description and basis document(s) (required in Requirement R1 of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing) as necessary to reflect the modified definition of 'Protection System' by the first day of the first calendar quarter twelve months following regulatory approvals and implement any additional maintenance and testing (required in Requirement R2 of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing) by the end of the first complete maintenance and testing cycle described in the entity's program description and basis document(s) following establishment of the program changes resulting from the revised definition.

The original definition of "Protection System" shall be retired at the same time the revised definition becomes effective.

Standards Announcement

Recirculation Ballot Open
November 1-11, 2010

Available at: https://standards.nerc.net/CurrentBallots.aspx

Project 2007-17 Protection System Maintenance Definition

A recirculation ballot period is open through **8 p.m. Eastern on November 11, 2010**.

Instructions

Members of the ballot pool associated with this project may log in and submit their votes from the following page: https://standards.nerc.net/CurrentBallots.aspx

Ballot Process

The Standards Committee encourages all members of the ballot pool to review the consideration of comments submitted during the successive ballot window that ended October 14, 2010 and the consideration of comments submitted during the formal comment period that ended October 12, 2010.

In the recirculation ballot, votes are counted by exception only. If a ballot pool member does not submit a revision to that member's original vote, the vote remains the same as in the first ballot. Members of the ballot pool may:

- Reconsider and change their vote from the first ballot.
- Vote in the second ballot even if they did not vote on the first ballot.
- Take no action if they do not want to change their original vote.

Additional Information

The Standard Processes Manual allows drafting teams to make changes following an initial or successive ballot with a goal of improving the quality of a standard (or definition), provided those changes do not alter the applicability or scope of the proposed standard (or definition). The Protection System Maintenance and Testing drafting team made the following minor edit to the implementation plan for the definition of Protection System:

- Removed PER-005-1 – System Personnel Training from the set of standards with conforming changes associated with the approval of the proposed definition of Protection System

A redline version of the Implementation Plan showing the above change has been posted for stakeholder review.

Next Steps

Voting results will be posted and announced after the ballot window closes. If approved, the definition and associated implementation plan will be submitted to the Board of Trustees.

Project Background

When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the Protection System and Maintenance Standard Drafting Team, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system," and directed that work to close this reliability gap should be given “priority.” The Standards Committee directed the team to advance the definition of Protection System in parallel with the development of PRC-005-2.

Project Page: http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Standards Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

Project 2007-17 Ballot Results for Definition of Protection System

The recirculation ballot window to vote on a proposed revision to the definition of the term, "Protection System" and its associated implementation plan closed on November 11, 2010. The ballot pool approved the revised definition and its associated implementation plan. Voting statistics are listed below, and the Ballot Results Web page provides a link to the detailed results:

Quorum: 89.41 %
Approval: 86.83 %

Next Steps

The revised definition and its associated implementation plan will be submitted to the NERC Board of Trustees for approval.

Project Background

When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the Protection System Maintenance and Testing Standard Drafting Team, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system," and directed that work to close this reliability gap should be given "priority." The Standards Committee directed the team to advance the definition of Protection System in parallel with the development of PRC-005-2.

Project Page: http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Ballot Criteria

Approval requires both a (1) quorum, which is established by at least 75% of the members of the ballot pool for submitting either an affirmative vote, a negative vote, or an abstention, and (2) a two-thirds majority of the weighted segment votes cast must be affirmative; the number of votes cast is the sum of affirmative and negative votes, excluding abstentions and non-responses.

Standards Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance, please contact Monica Benson,
Standards Process Administrator, at monica.benson@nerc.net or at 609.452.8060.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Standards Committee approves SAR for posting on June 5, 2007.
2. The SAR was posted for comment from June 11, 2007–July 10, 2007.
3. The SC approves development of the standard on August 13, 2007.
4. First posting of revised standard on July 24, 2009.
5. Second posting of revised standard on June 11, 2010
6. Third posting of revised standard on September 24, 2010

Description of Current Draft:
This is the third draft of the Standard. This standard merges previous standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0. It also addresses FERC comments from Order 693, and addresses observations from the NERC System Protection and Control Task Force, as presented in *NERC SPCTF Assessment of Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs, PRC-011-0 — UVLS System Maintenance and Testing, PRC-017-0 — Special Protection System Maintenance and Testing.*

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post for combined 30-day comment and ballot.	November 17-December 17, 2010
2. Conduct successive ballot	December 7– December 17, 2010
3. Drafting Team Responds to Comments	January 5, 2011–January 25, 2011

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- Restore — Return malfunctioning components to proper operation.

Protection System (modification)

- Protective relays which respond to electrical quantities,
- communications systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The following terms are defined for use only within PRC-005-2, and should remain with the standard upon approval rather than being moved to the Glossary of Terms.

Maintenance Correctable Issue – Failure of a component to operate within design parameters such that it cannot be restored to functional order by repair or calibration during performance of the initial on-site activity. Therefore this issue requires follow-up corrective action.

Segment – Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.

Component Type - Any one of the five specific elements of the Protection System definition.

Component – A component is any individual discrete piece of equipment included in a Protection System, such as a protective relay or current sensing device. For components such as control circuits, the designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a "local zone of protection" basis. Thus, entities are allowed the latitude to designate their own definitions of "control circuit components." Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

Countable Event – Any failure of a component which requires repair or replacement, any condition discovered during the verification activities in Tables 1-1 through 1-5 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are *not* included in Countable Events.

A. Introduction

1. Title: **Protection System Maintenance**

2. Number: PRC-005-2

3. Purpose: To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained.

4. Applicability:

4.1. Functional Entities:

4.1.1 Transmission Owners

4.1.2 Generator Owners

4.1.3 Distribution Providers

4.2. Facilities:

4.2.1 Protection Systems applied on, or designed to provide protection for, the BES.

4.2.2 Protection Systems used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

4.2.3 Protection Systems used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

4.2.4 Protection Systems installed as a Special Protection System (SPS) for BES reliability.

4.2.5 Protection Systems for generator Facilities that are part of the BES, including:

4.2.5.1 Protection Systems that act to trip the generator either directly or via generator lockout or auxiliary tripping relays.

4.2.5.2 Protection Systems for generator step-up transformers for generators that are part of the BES.

4.2.5.3 Protection Systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

4.2.5.4 Protection Systems for generator-connected station service transformers for generators that are part of the BES.

4.2.5.5 Protection Systems for system-connected station service transformers for generators that are part of the BES.

5. (Proposed) Effective Date: See Implementation Plan

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems applied on, or designed to provide protection for, the BES. The PSMP shall: *[Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]*

1.1. Address all Protection System component types.

1.2. Identify which Protection System component types are addressed through time-based, performance-based (per PRC-005 Attachment A), or a combination of these maintenance methods (per PRC-005-Attachment A). All batteries associated with the station dc supply component of a Protection System shall be included in a time-based program as described in Table 1-4.

1.3. Identify the associated maintenance intervals for time-based programs

1.4. Include all monitoring attributes and related maintenance activities applied to each Protection System component type, to include those specified in Tables 1-1 through 1-5.

1.5. Identify calibration tolerances or other equivalent parameters for each Protection System component type that establish acceptable parameters for the conclusion of maintenance activities.

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses maintenance intervals for monitored Protection Systems described in Tables 1-1 through 1-5, shall verify those components possess the monitoring attributes identified in Tables 1-1 through 1-5 in its PSMP. *[Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

R4. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP, including identification of the resolution of all maintenance correctable issues as follows: *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

4.1. Perform the maintenance activities for all Protection System components according to the PSMP established in accordance with Requirement R1:

4.1.1. For time-based maintenance programs, perform maintenance activities no less frequently than the maximum allowable intervals established in Tables 1-1 through 1-5.

4.1.2. For performance-based maintenance programs, perform the maintenance activities no less frequently than the intervals established in Requirement R3.

4.2. Either verify that the components are within the acceptable parameters established in accordance with Requirement R1, Part 1.5 at the conclusion of the maintenance activities, or initiate resolution of any identified maintenance correctable issues.

C. Measures

M1. Each Transmission Owner, Generator Owner and Distribution Provider shall have a current or updated documented Protection System Maintenance Program that addresses all component types of its Protection Systems, as required by Requirement R1. For each Protection System component type, the documentation shall include the type of maintenance program applied (time-based, performance-based, or a combination of these maintenance methods), maintenance activities, and maintenance intervals as specified in Requirement R1, Parts 1.1 through 1. 5.

M2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses maintenance intervals for monitored Protection Systems shall have evidence such as engineering drawings or manufacturer's information showing that the components possess the monitoring attributes identified in Tables 1-1 through 1-5, as required by Requirement R2.

M3. Each Transmission Owner, Generator Owner, and Distribution Provider that uses a performance-based maintenance program shall have evidence such as equipment lists, dated maintenance records, and dated analysis records and results that its current performance-based maintenance program is in accordance with Requirement R3.

M4. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence such as dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records or dated work orders as evidence that it has implemented the Protection System Maintenance Program and initiated resolution of identified maintenance correctable issues in accordance with Requirement R4.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Regional Entity

1.2. Compliance Monitoring and Enforcement Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

1.3. Data Retention

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to demonstrate compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated Protection System Maintenance Program including the documentation that specifies the type of maintenance program applied for each Protection System component type.

For R2, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep the evidence that proves the Protection System components possess the identified monitoring attributes as long as they are used to justify the intervals and activities associated with a performance-based maintenance program as identified within Tables 1-1 through 1-5.

For R3 and R4, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous scheduled audit date, whichever is longer.

The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records.

1.4. Additional Compliance Information

None.

2. Violation Severity Levels

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	Failed to specify whether one component type is being addressed by time-based or performance-based maintenance.	Failed to specify whether two component types are being addressed by time-based or performance-based maintenance.	Failed to include station batteries in a time-based program OR Failed to include all maintenance activities relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5. OR Failed to establish calibration tolerance or equivalent parameters to determine if components are within acceptable parameters.	Entity has not established a PSMP. OR The entity's PSMP failed to address three or more component types included in the definition of 'Protection System' OR Failed to specify whether three or more component types are being addressed by time-based or performance-based maintenance.
R2	Entity has Protection System components in a condition-based PSMP, but documentation to support the monitoring attributes used to determine relevant intervals is incomplete on no more than 5% of the Protection System components maintained according to Tables 1-1 through 1-5.	Entity has Protection System elements in a condition-based PSMP, but documentation to support monitoring attributes used to determine relevant intervals is incomplete on more than 5%, but 10% or less, of the Protection System components maintained according to Tables 1-1 through 1-5.	Entity has Protection System elements in a condition-based PSMP, but documentation to support monitoring attributes used to determine relevant intervals is incomplete on more than 10%, but 15% or less, of the Protection System components maintained according to Tables 1-1 through 1-5.	Entity has Protection System elements in a condition-based PSMP, but documentation to support monitoring attributes used to determine relevant intervals is incomplete on more than 15% of the Protection System components maintained according to Tables 1-1 through 1-5.
R3	Entity has Protection System elements in a performance-based PSMP but has: 1) Failed to reduce countable events to less than 4% within three years OR 2) Failed to annually document program activities, results, maintenance dates, or countable events for 5% or less of components in any individual segment	NA	Entity has Protection System elements in a performance-based PSMP but has failed to reduce countable events to less than 4% within four years.	Entity has Protection System components in a performance-based PSMP but has: 1) Failed to reduce countable events to less than 4% within five years OR 2) Failed to annually document program activities, results, maintenance dates, or countable events for over 5% of components

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
	OR 3) Maintained a segment with 54-59 components or containing different manufacturers.			in any individual segment OR 3) Maintained a segment with less than 54 components OR 4) Failed to: • Annually update the list of components, • Perform maintenance on the greater of 5% of the segment population or 3 components, • Annually analyze the program activities and results for each segment.
R4	Entity has failed to complete scheduled program on 5% or less of total Protection System components. OR Entity has failed to initiate resolution on 5% or less of identified maintenance-correctable issues.	Entity has failed to complete scheduled program on greater than 5%, but no more than 10% of total Protection System components OR Entity has failed to initiate resolution on greater than 5%, but no more than 10% of identified maintenance-correctable issues.	Entity has failed to complete scheduled program on greater than 10%, but no more than 15% of total Protection System components OR Entity has failed to initiate resolution on greater than 10%, but no more than 15% of identified.	Entity has failed to complete scheduled program on greater than 15% of total Protection System components OR Entity has failed to initiate resolution on greater than 15% of identified maintenance-correctable issues.

E. Regional Variances

None

F. Supplemental Reference Documents

The following documents present a detailed discussion about determination of maintenance intervals and other useful information regarding establishment of a maintenance program.

1. PRC-005-2 Protection System Maintenance Supplementary Reference — July 2009.
2. NERC Protection System Maintenance Standard PRC-005-2 FREQUENTLY ASKED QUESTIONS — Practical Compliance and Implementation DRAFT 1.0 — June 2009

Version History

Version	Date	Action	Change Tracking
2	TBD	Complete revision, absorbing maintenance requirements from PRC-005-1, PRC-008-0, PRC-011-0, PRC-017	Complete revision

Table 1-1 Component Type - Protective Relay **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	Verify that settings are as specified For non-microprocessor relays: • Test and calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following:: • Internal self diagnosis and alarming. • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self monitoring and alarming (see Table 2). • Alarming for power supply failure (see Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.
Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error. (See Table 2) • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure. (See Table 2) • Alarming for change of settings. (See Table 2)	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 1-2 Component Type - Communications Systems **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Activities**
Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	3 calendar months	Verify that the communications system is functional.
	6 calendar years	Verify that the channel meets performance criteria such as signal level, reflected power, or data error rate. Verify essential signals to and from other Protection System components.
Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function. (See Table 2)	12 calendar years	Verify that the channel meets performance criteria such as signal level, reflected power, or data error rate. Verify essential signals to and from other Protection System components.
Any communications system with continuous monitoring or periodic automated testing for the performance of the channel using criteria such as signal level, reflected power, or data error rate, and alarming for excessive performance degradation. (See Table 2)	No periodic maintenance specified	None.

Table 1-3 **Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays** **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Activities**
Any voltage and current sensing devices not having monitoring attributes of the category below.	12 calendar years	Verify that acceptable measurements of the current and voltage signals are received by the protective relays.
Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value as measured by the microprocessor relay to an independent ac measurement source, with alarming for unacceptable error or failure.	No periodic maintenance specified	None.

Table 1-4 Component Type - Station dc Supply **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Activities**
Any dc supply for a UFLS or UVLS system.	When control circuits are verified	Verify dc supply voltage
Any unmonitored station dc supply not having the monitoring attributes of a category below. (excluding UFLS and UVLS)	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level (excluding valve-regulated lead acid batteries) • For unintentional grounds
	18 Calendar Months	Verify: • State of charge of the individual battery cells/units • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure) Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack • Condition of non-battery-based dc supply
Any unmonitored Station dc supply in which a battery is not used and not having the monitoring attributes of a category below. (excluding UFLS and UVLS)	6 Calendar Years	Verify that the dc supply can perform as designed when ac power from the grid is not present.
Unmonitored Station dc supply with Valve Regulated Lead-Acid (VRLA) batteries that does not have the monitoring attributes of a category below. (excluding UFLS and UVLS)	3 Calendar Months	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline.

Table 1-4 Component Type - Station dc Supply **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Activities**
	-------------------------------- or --------------------------------	
	3 Calendar Years	Verify that the station battery can perform as designed by conducting a performance or service capacity test of the entire battery bank.
Unmonitored Station dc supply with Vented Lead-Acid Batteries (VLA) that does not have the monitoring attributes of a category below. (excluding UFLS and UVLS)	18 Calendar Months	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline.
	-------------------------------- or --------------------------------	
	6 Calendar Years	Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.
Unmonitored Station dc supply with Nickel-Cadmium (Ni-Cad) batteries that does not have the monitoring attributes of a category below. (excluding UFLS and UVLS)	6 Calendar Years	Verify that the station battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.
Monitored Station dc supply (excluding UFLS and UVLS) with: Monitor and alarm for variations from defined levels (See Table 2): • Station dc supply voltage (voltage of battery charger) • State of charge of the individual battery cell/units • Battery continuity of station battery • Cell-to-cell (if available) and battery terminal resistance	18 calendar months	Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack • Condition of non-battery-based dc supply

Table 1-4 Component Type - Station dc Supply **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Activities**
• Electrolyte level of all cells in a station battery • Unintentional dc grounds • Cell/unit internal ohmic values of station battery	6 calendar years	Verify that the monitoring devices are calibrated (where necessary)
Continuously monitored Station dc supply (excludes UFLS and UVLS) with preceding row attributes and the following: • The monitoring devices themselves are monitored.	18 calendar months	Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack • Condition of non-battery-based dc supply

Table 1-5 **Component Type - Control Circuitry** **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Activities**
Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices (excluding UFLS or UVLS systems).	6 calendar years	Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.
Trip coils of circuit breakers and interrupting devices in UFLS or UVLS systems.	No periodic maintenance specified	None.
Electromechanical trip or auxiliary devices	6 calendar years	Verify electrical operation of electromechanical trip and auxiliary devices
Unmonitored Control circuitry associated with protective functions	12 calendar years	Verify all paths of the control and trip circuits.
Control circuitry whose continuity and energization or ability to operate are monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

Table 2 – Alarming Paths In Tables 1-1 through 1-5, alarm attributes used to justify extended maximum maintenance intervals and/or reduced maintenance activities are subject to the following maintenance requirements		
Component Attributes	**Maximum Maintenance Interval**	**Activities**
Any alarm path through which alarms in Tables 1-1 through 1-5 are conveyed from the alarm origin to the location of corrective action, and not having all the attributes of the category below. Alarms are automatically reported within 24 hours of DETECTION to a location where corrective action can be taken.	When alarm producing device or system is verified	Verify that the alarm signals are conveyed to a location where corrective action can be taken.
Alarm Path with monitoring: The location where corrective action is taken receives an alarm within 24 hours for failure of any portion of the alarming path from the alarm origin to the location where corrective action can be taken.	No periodic maintenance specified	None.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of components included in each designated segment of the Protection System component population.
2. Maintain the components in each segment according to the time-based maximum allowable intervals established in Tables 1-1through 1-5 until results of maintenance activities for the segment are available for a minimum of 30 individual components of the segment.
3. Document the maintenance program activities and results for each segment, including maintenance dates and countable events[1] for each included component.
4. Analyze the maintenance program activities and results for each segment to determine the overall performance of the segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System components and segments and/or description if any changes occur within the segment.
2. Perform maintenance on the greater of 5% of the components (addressed in the performance based PSMP) in each segment or 3 individual components within the segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each segment to determine the overall performance of the segment.
4. If the components in a Protection System segment maintained through a performance-based PSMP experience 4% or more countable events, develop, document, and implement an action plan to reduce the countable events to less than 4% of the segment population within 3 years.
5. Using the prior year's data, determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

[1] Countable events include any failure of a component requiring repair or replacement, any condition discovered during the verification activities in Table 1a through Table 1c which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure.

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- ~~Verification — A means of determining~~Verify — Determine that the component is functioning correctly.
- ~~Monitoring — Observation of~~Monitor — Observe the routine in-service operation of the component.
- ~~Testing — Application of~~Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- ~~Inspection — To detect~~Inspect — Detect visible signs of component failure, reduced performance and degradation.
- ~~Calibration — Adjustment of~~Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- ~~Upkeep — Routine activities necessary to assure that the component remains in good working order and implementation of any manufacturer's hardware and software service advisories which are relevant to the application of the device.~~
- ~~Restoration — The actions to restore proper operation of~~ Restore — Return malfunctioning components to proper operation.

Protection System (modification)

- ~~—~~Protective relays~~, communication~~ which respond to electrical quantities,
- communications systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays ~~and associated circuitry from the voltage and current sensing devices, ,~~
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions ~~from the station dc supply~~ through the trip coil(s) of the circuit breakers or other interrupting devices.

The following terms are defined for use only within PRC-005-2, and should remain with the standard upon approval rather than being moved to the Glossary of Terms.

Maintenance Correctable Issue – Failure of a component to operate within design parameters such that it cannot be restored to functional order by repair or calibration during performance of the initial on-site activity. Therefore this issue requires follow-up corrective action.

Segment – Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.

Component Type - Any one of the five specific elements of the Protection System definition.

Component – A component is any individual discrete piece of equipment included in a Protection System, such as a protective relay or current sensing device. For components such as control circuits, the designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a "local zone of protection" basis. Thus, entities are allowed the latitude to designate their own definitions of "control circuit components." Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

Countable Event – Any failure of a component which requires repair or replacement, any condition discovered during the verification activities in Tables 1-1 through 1-5 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are *not* included in Countable Events.

A. Introduction

1. **Title:** **Protection System Maintenance**

2. **Number:** PRC-005-2

3. **Purpose:** To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained.

4. **Applicability:**

   4.1. Functional Entities:

   4.1.1 Transmission Owners

   4.1.2 Generator Owners

   4.1.3 Distribution Providers

   4.2. Facilities:

   4.2.1 Protection Systems applied on, or designed to provide protection for, the BES.

   4.2.2 Protection ~~System components~~Systems used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

   4.2.3 Protection ~~System components~~Systems used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

   4.2.4 Protection ~~System components~~Systems installed as a Special Protection System (SPS) for BES reliability.

   4.2.5 Protection Systems for generator Facilities that are part of the BES, including:

   4.2.5.1 Protection ~~System components~~Systems that act to trip the generator either directly or via generator lockout or auxiliary tripping relays.

   4.2.5.2 Protection Systems for generator step-up transformers for generators that are part of the BES.

   4.2.5.3 Protection Systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

   4.2.5.4 Protection Systems for generator-connected station service transformers for generators that are part of the BES.

   4.2.5.5 Protection Systems for system-connected station service transformers for generators that are part of the BES.

5. **(Proposed) Effective Date:** See Implementation Plan

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems ~~that use measurements of voltage, current, frequency and/or phase angle to determine~~

~~anomalies and to trip a portion of the BES[1] and that are~~ applied on, or ~~are~~ designed to provide protection for, the BES. The PSMP ~~must~~shall: *[Violation Risk Factor: ~~High~~Medium] [Time Horizon: Long Term Planning]*

1.1. ~~Identify~~Address all Protection System ~~components;~~component types.

~~**1.2.**~~ Identify ~~whether each~~which Protection System component ~~is~~types are addressed through time-based ~~(per Table 1a), condition-based (per Table 1b or 1c),~~, performance-based (per PRC-005 Attachment A), or a combination of these maintenance methods ~~and identify the associated maintenance interval;~~

~~**1.3.** For each Protection System component, include all maintenance activities specified in Tables 1a, 1b, or 1c associated with the maintenance method used per Requirement 1, part 1.1; and~~

~~1.4.~~**1.2.** ~~Include all~~ (per PRC-005-Attachment A). All batteries associated with the station dc supply component of a Protection System shall be included in a time-based program as described in Table 1-4.

1.3. Identify the associated maintenance intervals for time-based programs

1.4. Include all monitoring attributes and related maintenance activities applied to each Protection System component type, to include those specified in Tables 1-1 through 1-5.

1.5. Identify calibration tolerances or other equivalent parameters for each Protection System component type that establish acceptable parameters for the conclusion of maintenance activities.

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses ~~condition-based~~ maintenance intervals ~~in its PSMP for partially or fully~~for monitored Protection Systems described in Tables 1-1 through 1-5, shall ~~ensure the~~verify those components ~~to which the condition-based criteria are applied,~~ possess the monitoring attributes identified in Tables ~~1b or 1c~~1-1 through 1-5 in its PSMP. *[Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: ~~Long Term~~Operations Planning]*

R4. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP, including identification of the resolution of all maintenance correctable issues[2] as follows: *[Violation Risk Factor: ~~Medium~~High] [Time Horizon: ~~Long Term~~Operations Planning]*

4.1. ~~For time-based or condition-based maintenance programs, perform~~ Perform the maintenance activities ~~detailed in Table 1 (for the appropriate monitoring~~

~~[1] Devices that sense non-electrical conditions, such as thermal or transformer sudden pressure relays are not included within the scope of this standard.~~

~~[2] A maintenance correctable issue is a failure of a device to operate within design parameters that cannot be restored to functional order by repair or calibration while performing the initial on-site maintenance activity, and that requires follow-up corrective action~~

~~level(s))~~ for all Protection System components according to the PSMP established ~~per~~in accordance with Requirement ~~R1within~~R1:

4.1.1. For time-based maintenance programs, perform maintenance activities no less frequently than the maximum allowable intervals ~~not to exceed those~~ established in Tables ~~1a, 1b, and 1c~~1-1 through 1-5.

4.1.2. For performance-based maintenance programs, perform the maintenance activities ~~detailed in Table 1 (for~~no less frequently than the ~~appropriate monitoring level(s)) for all Protection System components in accordance within the maximum allowable~~ intervals established ~~per~~in Requirement R3.

4.2. ~~Ensure either~~Either verify that the components are within the acceptable parameters established in accordance with Requirement R1, Part 1.5 at the conclusion of the maintenance activities, or initiate resolution of any ~~necessary activities to correct unresolved~~ identified maintenance correctable issues[3].

C. Measures

M1. Each Transmission Owner, Generator Owner and Distribution Provider ~~will~~shall have a current or updated documented Protection System Maintenance Program that addresses ~~protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from the station dc supply through the trip coil(s)~~all component types of ~~the circuit breakers or other interrupting devices~~its Protection Systems, as required by Requirement R1. For each ~~protection system~~Protection System component type, the documentation shall include the type of maintenance program applied~~,~~ (time-based, performance-based, or a combination of these maintenance methods), maintenance activities, and maintenance intervals as specified in Requirement R1, Parts 1.1 through 1.~~4~~ 5.

M2. Each Transmission Owner~~ and~~, Generator Owner, and Distribution Provider that uses ~~a condition-based~~ maintenance ~~program should~~intervals for monitored Protection Systems shall have evidence such as engineering drawings or manufacturer's information showing that the components possess the monitoring attributes identified in Tables ~~1b or 1c~~1-1 through 1-5, as required by Requirement R2.

M3. Each Transmission Owner, Generator Owner, ~~or~~and Distribution Provider that uses a performance-based maintenance program ~~should~~shall have evidence such as equipment lists, dated maintenance records, and dated analysis records and results that its current performance-based maintenance program is in accordance with Requirement R3.

M4. Each Transmission Owner, Generator Owner, ~~or~~and Distribution Provider shall have evidence such as dated maintenance records~~ or~~, dated maintenance summaries~~ (including dates that the components were maintained) that~~, dated check-off lists, dated inspection records or

[3] ~~A maintenance correctable issue is a failure of a device to operate within design parameters that cannot be restored to functional order by repair or calibration while performing the initial on-site maintenance activity and that requires follow-up corrective action.~~

dated work orders as evidence that it has implemented the Protection System Maintenance Program and initiated resolution of identified maintenance correctable issues in accordance with Requirement R4.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Regional Entity

~~**1.2. Compliance Monitoring Period and Reset Time Frame**~~

~~Not Applicable~~

~~1.3.~~1.2. Compliance Monitoring and Enforcement Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

~~1.4.~~1.3. Data Retention

The Transmission Owner, Generator Owner, and Distribution Provider shall each ~~retain~~keep data or evidence to demonstrate compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated Protection System Maintenance Program including the documentation that specifies the type of maintenance program applied for each Protection System component type.

For R2, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep the evidence that proves the Protection System components possess the identified monitoring attributes as long as they are used to justify the intervals and activities associated with a performance-based maintenance program as identified within Tables 1-1 through 1-5.

For R3 and R4, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous ~~on-site~~scheduled audit date, whichever is longer.

The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records.

~~1.5.~~1.4. Additional Compliance Information

None.

2. Violation Severity Levels

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	~~The entity's PSMP included all of the 'types' of components included in the definition of 'Protection System', but, for no more than 5% of the components, failed~~Failed to ~~either~~ ~~• identify the component,~~ specify whether ~~the~~one component type is being addressed by time-based~~, condition-based,~~ or performance-based maintenance~~, or~~. ~~Include all maintenance activities specified in Table 1a, Table 1b, or Table 1c, as applicable.~~	~~The entity's PSMP included all of the 'types' of components included in the definition of 'Protection System', but, for grater than 5%, but no more than 10% of the components, failed~~Failed to ~~either~~ ~~• identify the component,~~ specify whether ~~the~~two component ~~is~~types are being addressed by time-based~~, condition-based,~~ or performance-based maintenance~~, or~~. ~~Include all maintenance activities specified in Table 1a, Table 1b, or Table 1c, as applicable.~~	~~The entity's PSMP included all of the 'types' of components included in the definition of 'Protection System', but, for greater than 10%, but no more than 15%, of the components, failed to either~~ ~~• identify the component,~~ ~~• specify whether the component is being addressed by time-based, condition-based, or performance-based maintenance, or~~ ~~Include~~Failed to include station batteries in a time-based program OR Failed to include all maintenance activities relevant for the identified monitoring attributes specified in ~~Table 1a, Table 1b, or Table 1c, as applicable~~Tables 1-1 through 1-5. ~~Table 1a — Time-Based Maintenance — Level 1 Monitoring~~

~~Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection System Components~~

~~**General Description:** Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures.~~

~~**General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~

Table 1-1

Component Type - Protective Relay

Note: Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.

~~Type of Protection System~~ Component Attributes	Maximum Maintenance Interval	~~Maintenance~~ Activities
~~**Protective Relays**~~Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 ~~**Calendar Years**~~calendar years	~~Test and calibrate the relays (other than microprocessor relays) with simulated electrical inputs. (Note 1)~~ Verify that settings are as specified ~~.~~ For non-microprocessor relays: • Test and calibrate For microprocessor relays~~, check~~: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • ~~For microprocessor relays, verify~~Verify acceptable measurement of power system input values.
~~Voltage and Current Sensing Inputs to Protective Relays and associated circuitry~~	~~12 Calendar Years~~	~~Verify proper functioning of the current and voltage signals necessary for Protection System operation from the voltage and current sensing devices to the protective relays.~~

~~Control and trip circuits with electromechanical trip or auxiliary contacts (except for~~ Monitored microprocessor ~~relays, UFLS~~protective relay with the following:: • Internal self diagnosis and alarming. • Voltage and/or current waveform sampling three or ~~UVLS)~~more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self monitoring and alarming (see Table 2). • Alarming for power supply failure (see Table 2).	~~6 Calendar Years~~12 calendar years	~~Perform a complete functional trip test that includes all sections~~Verify: • Settings are as specified. • Operation of the ~~Protection System control~~relay inputs and ~~trip circuits, including all electromechanical trip and auxiliary contacts~~outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.
~~Control and trip circuits with unmonitored solid-state trip or auxiliary contacts (except for UFLS or UVLS)~~Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error. (See Table 2) • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure. (See Table 2) • Alarming for change of settings. (See Table 2)	12 ~~Calendar Years~~calendar years	~~Perform a complete functional trip test that includes all sections of~~Verify only the ~~Protection System control~~unmonitored relay inputs and ~~trip circuits, including all solid-state trip and auxiliary contacts (e.g. paths with no moving parts), devices, and connections~~outputs that are essential to proper functioning of the Protection System.
~~Control and trip circuits with electromechanical trip or auxiliary (UFLS/UVLS Systems Only)~~	~~6 Calendar Years~~	~~Perform a complete functional trip test that includes all sections of the Protection System control and trip circuits, including all electromechanical trip and auxiliary contacts essential to proper functioning of the Protection System, except .that verification does not require actual tripping of circuit breakers or interrupting devices.~~
~~Control and trip circuits with unmonitored solid-state trip or auxiliary contacts (UFLS/UVLS Systems Only)~~	~~12 Calendar Years~~	~~Perform a complete functional trip test that includes all sections of the Protection System control and trip circuit, including all solid-state trip and auxiliary contacts (e.g. paths with no moving parts), devices, and connections essential to proper functioning of the Protection System, except that verification does not require actual tripping of circuit breakers or interrupting devices.~~

~~Table 1a — Time-Based Maintenance — Level 1 Monitoring~~

~~Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection System Components~~

~~**General Description:** Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures.~~

~~**General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~

Table 1-1

Component Type - Protective Relay

Note: Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.

~~Type of Protection System~~ Component Attributes	Maximum Maintenance Interval	~~Maintenance~~ Activities
~~**Protective Relays**~~Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 ~~**Calendar Years**~~calendar years	~~Test and calibrate the relays (other than microprocessor relays) with simulated electrical inputs. (Note 1)~~ Verify that settings are as specified ~~.~~ For non-microprocessor relays: • Test and calibrate For microprocessor relays~~, check~~: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • ~~For microprocessor relays, verify~~Verify acceptable measurement of power system input values.

~~Station dc Supply (used only for UVLS or UFLS)~~	~~(when the associated UVLS or UFLS system is maintained)~~	~~Verify proper voltage of the dc supply.~~

~~**Table 1a — Time-Based Maintenance — Level 1 Monitoring**~~

~~**Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection System Components**~~

~~**General Description:** Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures.~~

~~**General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~

Table 1-1

Component Type - Protective Relay

Note: Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.

~~Type of Protection System~~ Component Attributes	Maximum Maintenance Interval	~~Maintenance~~ Activities
~~**Protective Relays**~~Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 ~~**Calendar Years**~~calendar years	~~Test and calibrate the relays (other than microprocessor relays) with simulated electrical inputs. (Note 1)~~ Verify that settings are as specified ~~.~~ For non-microprocessor relays: • Test and calibrate For microprocessor relays~~, check~~: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • ~~For microprocessor relays, verify~~Verify acceptable measurement of power system input values.
~~Station dc supply~~	~~18 Calendar Months~~	~~Verify:~~ • ~~State of charge of the individual battery cell/units~~ • ~~Float voltage of battery charger~~ • ~~Battery continuity~~ • ~~Battery terminal connection resistance~~ • ~~Battery cell-to-cell connection resistance~~ ~~Inspect:~~ • ~~Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible~~ • ~~Physical condition of battery rack~~ • ~~The condition of non-battery-based dc supply~~

~~Table 1a — Time-Based Maintenance — Level 1 Monitoring~~ ~~Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection System Components~~ ~~**General Description:** Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures.~~ ~~**General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~ **Table 1-1** **Component Type - Protective Relay** **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.

~~SPS~~	~~See Maintenance Activities~~	~~Perform all of the Maintenance activities listed above as established for components of the SPS at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the SPS components whose operation leads to that control action must each be verified.~~

~~Table 1b — Condition-Based Maintenance - Level 2 Monitoring~~ ~~Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components~~ ~~**General Description:** Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring includes all monitoring attributes as listed below for the individual type of component.~~ ~~**General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~**Table 1-2** **Component Type - Communications Systems** **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.			
~~**Type of Protection System Component**~~	~~**Level 2 Monitoring**~~**Component Attributes** ~~**for Component**~~	**Maximum Maintenance Interval**	~~**Maintenance**~~ **Activities**
~~Protective Relays~~	~~Includes~~ • ~~Internal self diagnosis and alarm capability~~ • ~~Alarm must assert for power supply failures~~ • ~~Input voltage or current waveform sampling three or more times per power cycle~~ ~~Conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming~~Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	~~12 Calendar Years~~ 3 calendar months	Verify that the ~~status of relays is normal with no alarms indicated.~~ ~~Verify acceptable measurement of power~~communications system ~~input values.~~ ~~For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the Protection System.~~ ~~Verify that settings are as specified.~~ ~~Verify that the relay alarms will be received at the location where action can be taken.~~ ~~Verify correct operation of output actions that are used for tripping~~is functional.

~~Table 1b — Condition-Based Maintenance - Level 2 Monitoring~~

~~Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components~~

~~**General Description:** Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring includes all monitoring attributes as listed below for the individual type of component.~~

~~**General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~**Table 1-2**

Component Type - Communications Systems

Note: Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.

~~Type of Protection System Component~~	**~~Level 2 Monitoring~~Component Attributes ~~for Component~~**	**Maximum Maintenance Interval**	**~~Maintenance~~ Activities**
~~Protective Relays~~	~~Includes~~ • ~~Internal self diagnosis and alarm capability~~ • ~~Alarm must assert for power supply failures~~ • ~~Input voltage or current waveform sampling three or more times per power cycle~~ ~~Conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming~~Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	~~12 Calendar Years~~ 3 calendar months	Verify that the ~~status of relays is normal with no alarms indicated.~~ ~~Verify acceptable measurement of power~~communications system ~~input values.~~ ~~For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the Protection System.~~ ~~Verify that settings are as specified.~~ ~~Verify that the relay alarms will be received at the location where action can be taken.~~ ~~Verify correct operation of output actions that are used for tripping~~is functional.
~~Voltage and Current Sensing Inputs to Protective Relays and associ~~	~~No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities~~	~~12 Calendar Years~~	~~Verify the proper functioning of current and voltage circuit signals necessary for Protection System operation from the voltage and current sensing devices to the protective relays.~~

~~Table 1b — Condition-Based Maintenance - Level 2 Monitoring~~

~~Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components~~

~~**General Description:** Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring includes all monitoring attributes as listed below for the individual type of component.~~

~~**General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~**Table 1-2**

Component Type - Communications Systems

Note: Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.

~~**Type of Protection System Component**~~	~~**Level 2 Monitoring**~~**Component Attributes** ~~**for Component**~~	**Maximum Maintenance Interval**	~~**Maintenance**~~ **Activities**
~~Protective Relays~~	~~Includes~~ • ~~Internal self diagnosis and alarm capability~~ • ~~Alarm must assert for power supply failures~~ • ~~Input voltage or current waveform sampling three or more times per power cycle~~ ~~Conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming~~Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	~~12 Calendar Years~~ 3 calendar months	Verify that the ~~status of relays is normal with no alarms indicated.~~ ~~Verify acceptable measurement of power~~communications system ~~input values.~~ ~~For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the Protection System.~~ ~~Verify that settings are as specified.~~ ~~Verify that the relay alarms will be received at the location where action can be taken.~~ ~~Verify correct operation of output actions that are used for tripping~~is functional.
~~Control Circuitry (Trip Coils and Auxiliary Relays)~~	~~Monitoring and alarming of continuity of trip circuits(s)~~	~~6 Calendar Years~~	~~Verify that each breaker trip coil, each auxiliary relay, and each lockout relay is electrically operated within this time interval.~~

~~Control Circuitry (Trip Circuits) (except for UFLS/UVLS)~~		6 calendar years	~~Monitoring of Protection System component inputs, outputs, and connections with reporting of monitoring alarms to a location where action can be taken~~ ~~**Connection paths using electronic signals or data messages are monitored by periodic signal changes or messages that verify ability to convey Protection System operating values**~~Verify that the channel meets performance criteria such as signal level, reflected power, or data error rate. Verify essential signals to and from other Protection System components.	~~12 Calendar Years~~	~~Verify that the alarms will be received at the location where action can be taken.~~
~~Control and trip circuitry~~	~~Monitoring of the continuity of breaker trip circuits along with the presence of tripping voltage supply all the way from relay terminals (or from inside the relay) through to the trip coil(s), including any auxiliary contacts essential to proper Protection System operation. If a trip circuit comprises multiple paths, each of the paths must be monitored, including monitoring of the operating coil circuit(s) and the tripping circuits of auxiliary tripping relays and lockout relays. Alarming for loss of continuity or dc supply for trip circuits is reported to a location where action can be taken.~~Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function. (See Table 2)	12 ~~Calendar Years~~ calendar years	Verify that the ~~alarms will be received at the location where action can be taken~~channel meets performance criteria such as signal level, reflected power, or data error rate. Verify essential signals to and from other Protection System components.		

~~Table 1b — Condition-Based Maintenance - Level 2 Monitoring~~ ~~Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components~~ ~~General Description: Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. ~~Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components~~

~~**General Description:** Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring includes all monitoring attributes as listed below for the individual type of component.~~

~~**General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~**Table 1-2**

Component Type - Communications Systems

Note: Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.

~~Type of Protection System Component~~	~~Level 2 Monitoring~~Component Attributes ~~for Component~~	Maximum Maintenance Interval	~~Maintenance~~ Activities
~~Protective Relays~~	~~Includes~~ • ~~Internal self diagnosis and alarm capability~~ • ~~Alarm must assert for power supply failures~~ • ~~Input voltage or current waveform sampling three or more times per power cycle~~ ~~Conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming~~Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	~~12 Calendar Years~~ 3 calendar months	Verify that the ~~status of relays is normal with no alarms indicated.~~ ~~Verify acceptable measurement of power~~communications system ~~input values.~~ ~~For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the Protection System.~~ ~~Verify that settings are as specified.~~ ~~Verify that the relay alarms will be received at the location where action can be taken.~~ ~~Verify correct operation of output actions that are used for tripping~~is functional.
~~Station dc supply (that has as a component Valve Regulated Lead~~	~~No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities~~	~~3 Calendar Years~~ ~~– or –~~ ~~3 Calendar Months~~	~~Verify that the station battery can perform as designed by conducting a performance or service capacity test of the entire battery bank. (3 calendar years)~~ ~~– or –~~ ~~Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (3 months)~~

~~Table 1b — Condition-Based Maintenance - Level 2 Monitoring~~

~~Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components~~

~~**General Description:** Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring includes all monitoring attributes as listed below for the individual type of component.~~

~~**General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~**Table 1-2**

Component Type - Communications Systems

Note: Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.

~~Type of Protection System Component~~	~~Level 2 Monitoring~~Component Attributes ~~for Component~~	Maximum Maintenance Interval	~~Maintenance~~ Activities
~~Protective Relays~~	~~Includes~~ • ~~Internal self diagnosis and alarm capability~~ • ~~Alarm must assert for power supply failures~~ • ~~Input voltage or current waveform sampling three or more times per power cycle~~ ~~Conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming~~Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	~~12 Calendar Years~~ 3 calendar months	Verify that the ~~status of relays is normal with no alarms indicated.~~ ~~Verify acceptable measurement of power~~communications system ~~input values.~~ ~~For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the Protection System.~~ ~~Verify that settings are as specified.~~ ~~Verify that the relay alarms will be received at the location where action can be taken.~~ ~~Verify correct operation of output actions that are used for tripping~~is functional.
~~Station dc supply (that has as a component Vented Lead-Acid batterie~~	~~No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities~~	~~6 Calendar Years~~ ~~- or -~~ ~~18 Calendar Months~~	~~Verify that the substation battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank. (6 calendar years)~~ ~~- or -~~ ~~Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (18 Months)~~

~~Table 1b — Condition-Based Maintenance - Level 2 Monitoring~~ ~~Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components~~ ~~General Description: Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring includes all monitoring attributes as listed below for the individual type of component.~~ ~~General Maintenance Requirements: Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~**Table 1-2** **Component Type - Communications Systems** **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.			
~~Type of Protection System Component~~	~~Level 2 Monitoring~~Component Attributes ~~for Component~~	Maximum Maintenance Interval	~~Maintenance~~ Activities
~~Protective Relays~~	~~Includes~~ • ~~Internal self diagnosis and alarm capability~~ • ~~Alarm must assert for power supply failures~~ • ~~Input voltage or current waveform sampling three or more times per power cycle~~ ~~Conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming~~Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	~~12 Calendar Years~~ 3 calendar months	Verify that the ~~status of relays is normal with no alarms indicated.~~ ~~Verify acceptable measurement of power~~communications system ~~input values.~~ ~~For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the Protection System.~~ ~~Verify that settings are as specified.~~ ~~Verify that the relay alarms will be received at the location where action can be taken.~~ ~~Verify correct operation of output actions that are used for tripping~~is functional.

~~Protective Relays~~	~~Includes~~ • ~~Internal self diagnosis and alarm capability~~ • ~~Alarm must assert for power supply failures~~ • ~~Input voltage or current waveform sampling three or more times per power cycle~~ ~~Conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming~~Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	~~12 Calendar Years~~ 3 calendar months	Verify that the ~~status of relays is normal with no alarms indicated.~~ ~~Verify acceptable measurement of power~~communications system ~~input values.~~ ~~For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the Protection System.~~ ~~Verify that settings are as specified.~~ ~~Verify that the relay alarms will be received at the location where action can be taken.~~ ~~Verify correct operation of output actions that are used for tripping~~is functional.
~~Station dc Supply (battery is not used)~~	~~No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities~~	~~6 Calendar Years~~	~~Verify that the dc supply can perform **as** designed when ac power from the grid is not present.~~

~~Associated communications system~~	~~Monitoring and alarming of protection communications system by mechanisms that check for presence of the communications channel.~~	~~12 Calendar Years~~	~~Verify that~~ Any communications system with continuous monitoring or periodic automated testing for the performance of the channel ~~and the quality of the channel meets performance~~ using criteria~~,~~ such as ~~via measurement of~~ signal level, reflected power, or data error rate~~.~~ ~~Verify proper functioning of communications equipment inputs and outputs that are essential to proper functioning of the Protection System.~~ ~~Verify the signals to/from the associated protective relay(s).~~ ~~Verify proper functioning of alarm notification.~~, and alarming for excessive performance degradation. (See Table 2)	No periodic maintenance specified	None.

~~Table 1b — Condition-Based Maintenance - Level 2 Monitoring~~

~~Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components~~

~~**General Description:** Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring includes all monitoring attributes as listed below for the individual type of component.~~

~~**General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~**Table 1-2**

Component Type - Communications Systems

Note: Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.

~~Type of Protection System Component~~	~~Level 2 Monitoring~~Component Attributes ~~for Component~~	Maximum Maintenance Interval	~~Maintenance~~ Activities
~~Protective Relays~~	~~Includes~~ • ~~Internal self diagnosis and alarm capability~~ • ~~Alarm must assert for power supply failures~~ • ~~Input voltage or current waveform sampling three or more times per power cycle~~ ~~Conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming~~Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	~~12 Calendar Years~~ 3 calendar months	Verify that the ~~status of relays is normal with no alarms indicated.~~ ~~Verify acceptable measurement of power~~communications system ~~input values.~~ ~~For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the Protection System.~~ ~~Verify that settings are as specified.~~ ~~Verify that the relay alarms will be received at the location where action can be taken.~~ ~~Verify correct operation of output actions that are used for tripping~~is functional.

~~UVLS and UFLS relays that comprise a protecti~~	~~Includes internal self diagnosis and alarm capability, which must assert for power supply failures.~~ ~~Includes input voltage or current waveform sampling three~~		~~Verify the status of relays as in service with no alarms.~~ ~~Verify acceptable measurement of power system input values the proper function of the A/D converters (if included in relay)~~

~~Table 1b — Condition-Based Maintenance - Level 2 Monitoring~~ ~~Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components~~ ~~General Description: Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring includes all monitoring attributes as listed below for the individual type of component.~~ ~~General Maintenance Requirements: Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~**Table 1-2** **Component Type - Communications Systems** **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.			
~~Type of Protection System Component~~	~~Level 2 Monitoring~~Component Attributes ~~for Component~~	Maximum Maintenance Interval	~~Maintenance~~ Activities
~~Protective Relays~~	~~Includes~~ • ~~Internal self diagnosis and alarm capability~~ • ~~Alarm must assert for power supply failures~~ • ~~Input voltage or current waveform sampling three or more times per power cycle~~ ~~Conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming~~Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	~~12 Calendar Years~~ 3 calendar months	Verify that the ~~status of relays is normal with no alarms indicated.~~ ~~Verify acceptable measurement of power~~communications system ~~input values.~~ ~~For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the Protection System.~~ ~~Verify that settings are as specified.~~ ~~Verify that the relay alarms will be received at the location where action can be taken.~~ ~~Verify correct operation of output actions that are used for tripping~~is functional.
~~Relay sensing for centralized UFLS or UVLS systems~~	~~See the attributes of Level 2 Monitoring forthe individual components of the SPS~~ ~~See Maintenance Intervals for the individual components of the UFLS/UVLS~~		~~Perform all of the Maintenance activities listed above as established for components of the UFLS or UVLS systems at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the UFLS or UVLS components whose operation leads to that control action must each be verified.~~

~~Table 1b — Condition-Based Maintenance - Level 2 Monitoring~~ ~~Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components~~ ~~General Description: Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring includes all monitoring attributes as listed below for the individual type of component.~~ ~~General Maintenance Requirements: Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~ **Table 1-2** **Component Type - Communications Systems** **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.			
~~Type of Protection System Component~~	~~Level 2 Monitoring~~Component Attributes ~~for Component~~	Maximum Maintenance Interval	~~Maintenance~~ Activities
~~Protective Relays~~	~~Includes~~ ~~• Internal self diagnosis and alarm capability~~ ~~• Alarm must assert for power supply failures~~ ~~• Input voltage or current waveform sampling three or more times per power cycle~~ ~~Conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming~~Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	~~12 Calendar Years~~ 3 calendar months	Verify that the ~~status of relays is normal with no alarms indicated.~~ ~~Verify acceptable measurement of power~~communications system ~~input values.~~ ~~For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the Protection System.~~ ~~Verify that settings are as specified.~~ ~~Verify that the relay alarms will be received at the location where action can be taken.~~ ~~Verify correct operation of output actions that are used for tripping~~is functional.
~~SPS~~	~~See the attributes of Level 2 Monitoring for the individual components of the SPS~~	~~See Maintenance Intervals for the individual components of the SPS~~	~~Perform all of the Maintenance activities listed above as established for components of the SPS, at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the SPS components whose operation leads to that control action must each be verified.~~

~~Table 1c — Condition-based Maintenance — Level 3 Monitoring~~

~~Maximum Allowable Testing Intervals and Maintenance Activities for Fully Monitored Protection System Components~~

~~**General Description:** Protection System components in which every function required for correct operation of that component is continuously monitored and verified, and detected maintenance-correctable issues reported. Level 3 Monitored Protection Systems also includes verification of the means by which alarms and monitored values are transmitted to a location where action can be taken. Detected maintenance-correctable issues for Level 3 Monitored Protection Systems must be reported within 1 hour or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 3 Monitoring includes all attributes of Level 2 Monitoring, with additional monitoring attributes as listed below for the individual type of component.~~

~~**General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~**Table 1-3**

Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays

Note: Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.

~~Type of Protection System Component~~	~~Level 3 Monitoring~~Component Attributes ~~for Component~~	Maximum Maintenance Interval	~~Maintenance~~ Activities
~~Protective Relays~~	~~Relay A/D converters are continuously monitored and alarmed~~	~~Continuous~~	~~Continuous verification of the status of the relays~~ ~~Alarm on change of settings~~
~~Protective Relays with trip contacts~~	~~All Level attributes, except relay possesses mechanical output contacts~~	~~12 Calendar Years~~	~~Verify proper functioning of the relay trip contacts.~~
~~Voltage and Current Sensing Inputs to Protective Relays and associated circuitry~~	~~Verification of the analog values (magnitude and phase angle) measured by the microprocessor relay or comparable device, by comparing against other measurements using other~~Any voltage and current sensing devices not having monitoring attributes of the category below.	~~Continuous~~ 12 calendar years	~~Continuous verification and comparison~~Verify that acceptable measurements of the current and voltage signals ~~from~~are received by the ~~voltage and current sensing devices of the Protection System~~protective relays.

~~Table 1c — Condition-based Maintenance — Level 3 Monitoring~~

~~Maximum Allowable Testing Intervals and Maintenance Activities for Fully Monitored Protection System Components~~

~~**General Description:** Protection System components in which every function required for correct operation of that component is continuously monitored and verified, and detected maintenance-correctable issues reported. Level 3 Monitored Protection Systems also includes verification of the means by which alarms and monitored values are transmitted to a location where action can be taken. Detected maintenance-correctable issues for Level 3 Monitored Protection Systems must be reported within 1 hour or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 3 Monitoring includes all attributes of Level 2 Monitoring, with additional monitoring attributes as listed below for the individual type of component.~~

~~**General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~**Table 1-3**

Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays

Note: Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.

~~Type of Protection System Component~~	~~Level 3 Monitoring~~Component Attributes ~~for Component~~	Maximum Maintenance Interval	~~Maintenance~~ Activities
~~Protection System control and trip circuitry~~	~~Monitoring and alarming of the alarm path itself~~	~~Continuous~~	~~Continuous verification of the status of the monitored control circuits~~
~~Station dc supply~~	~~No Level 3 monitoring attributes are defined – use Level 1 Maintenance Activities and intervals~~	~~18 Calendar Months~~	~~Inspect:~~ • ~~Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible~~ • ~~Physical condition of battery rack~~ • ~~The condition of non-battery-based dc supply~~
~~Station dc supply (that has as a component Valve Regulated Lead-Acid batteries)~~	~~No Level 3 monitoring attributes are defined – use Level 1 Maintenance Activities and intervals~~	~~3 Calendar Years~~ ~~– or –~~ ~~3 Calendar Months~~	~~Verify that the station battery can perform as designed by conducting a performance or service capacity test of the entire battery bank. (3 calendar years)~~ ~~- or -~~ ~~Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (3 months)~~

~~**General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~**Table 1-3**

Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays

Note: Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.

~~**Type of Protection System Component**~~	~~**Level 3 Monitoring**~~Component **Attributes** ~~**for Component**~~	**Maximum Maintenance Interval**	~~**Maintenance**~~ **Activities**
~~Station dc Supply which do not use a station battery~~	~~No Level 3 monitoring attributes are defined – use Level 1 Maintenance Activities and intervals~~	~~6 Calendar Years~~	~~Verify that the dc supply can perform as designed when the ac power from the grid is not present.~~
~~Associated communications systems~~	~~Evaluating the performance of the channel and its interface to protective relays to determine the quality of the channel and alarming if the channel does not meet performance criteria~~	~~Continuous~~	~~Continuous verification that the performance and quality of the channel meets performance criteria is provided.~~ ~~Continuous verification of the communications equipment alarm system is provided.~~

~~Table 1c — Condition-based Maintenance — Level 3 Monitoring~~

~~Maximum Allowable Testing Intervals and Maintenance Activities for Fully Monitored Protection System Components~~

~~**General Description:** Protection System components in which every function required for correct operation of that component is continuously monitored and verified, and detected maintenance-correctable issues reported. Level 3 Monitored Protection Systems also includes verification of the means by which alarms and monitored values are transmitted to a location where action can be taken. Detected maintenance-correctable issues for Level 3 Monitored Protection Systems must be reported within 1 hour or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 3 Monitoring includes all attributes of Level 2 Monitoring, with additional monitoring attributes as listed below for the individual type of component.~~

~~**General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.~~

Table 1-3

Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays

Note: Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.

~~**Type of Protection System Component**~~	~~**Level 3 Monitoring**~~Component **Attributes** ~~**for Component**~~	**Maximum Maintenance Interval**	~~**Maintenance**~~ **Activities**
~~UVLS and UFLS relays that comprise a protection scheme distributed over the power system.~~	~~The relay A/D converters are continuously monitored and alarmed.~~	~~Continuous~~	~~Continuous verification of the status of the relays~~ ~~Alarm on change of settings~~ ~~Verification does not require actual tripping of circuit breakers or interrupting devices~~

~~Relay sensing for centralized UFLS or UVLS systems.~~	~~See the attributes of Level 3 Monitoring for the individual components of the UFLS/UVLS~~	~~See Maintenance Activities~~	~~Perform all of the Maintenance activities listed above as established for components of the UFLS or UVLS systems at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the UFLS or UVLS components whose operation leads to that control action must each be verified.~~Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value as measured by the microprocessor relay to an independent ac measurement source, with alarming for unacceptable error or failure.	No periodic maintenance specified	None.

~~SPS~~	~~See the attributes of Level 3 Monitoring for the individual components of the SPS~~	~~See Maintenance Activities~~	~~Perform all of the Maintenance activities listed above as established for components of the SPS at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the SPS components whose operation leads to that control action must each be verified.~~

~~**Notes for Table 1a, Table 1b, and Table 1c**~~

~~For some Protection System components, adjustment is required to bring measurement accuracy within parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.~~

Table 1-4 Component Type - Station dc Supply **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Activities**
Any dc supply for a UFLS or UVLS system.	When control circuits are verified	Verify dc supply voltage
Any unmonitored station dc supply not having the monitoring attributes of a category below. (excluding UFLS and UVLS)	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level (excluding valve-regulated lead acid batteries) • For unintentional grounds
	18 Calendar Months	Verify: • State of charge of the individual battery cells/units • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure) Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack • Condition of non-battery-based dc supply
Any unmonitored Station dc supply in which a battery is not used and not having the monitoring attributes of a category below. (excluding UFLS and UVLS)	6 Calendar Years	Verify that the dc supply can perform as designed when ac power from the grid is not present.
Unmonitored Station dc supply with Valve Regulated Lead-Acid (VRLA) batteries that does not have the monitoring attributes of a category below. (excluding UFLS and UVLS)	3 Calendar Months	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline.

Table 1-4 Component Type - Station dc Supply **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Activities**
	-------------------------------- or --------------------------------	
	3 Calendar Years	Verify that the station battery can perform as designed by conducting a performance or service capacity test of the entire battery bank.
Unmonitored Station dc supply with Vented Lead-Acid Batteries (VLA) that does not have the monitoring attributes of a category below. (excluding UFLS and UVLS)	18 Calendar Months	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline.
	-------------------------------- or --------------------------------	
	6 Calendar Years	Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.
Unmonitored Station dc supply with Nickel-Cadmium (Ni-Cad) batteries that does not have the monitoring attributes of a category below. (excluding UFLS and UVLS)	6 Calendar Years	Verify that the station battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.
Monitored Station dc supply (excluding UFLS and UVLS) with: Monitor and alarm for variations from defined levels (See Table 2): • Station dc supply voltage (voltage of battery charger) • State of charge of the individual battery cell/units • Battery continuity of station battery • Cell-to-cell (if available) and battery terminal resistance	18 calendar months	Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack • Condition of non-battery-based dc supply

Table 1-4 **Component Type - Station dc Supply** **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Activities**
• Electrolyte level of all cells in a station battery • Unintentional dc grounds • Cell/unit internal ohmic values of station battery	6 calendar years	Verify that the monitoring devices are calibrated (where necessary)
Continuously monitored Station dc supply (excludes UFLS and UVLS) with preceding row attributes and the following: • The monitoring devices themselves are monitored.	18 calendar months	Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack • Condition of non-battery-based dc supply

Table 1-5
Component Type - Control Circuitry
Note: Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.

Component Attributes	Maximum Maintenance Interval	Activities
Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices (excluding UFLS or UVLS systems).	6 calendar years	Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.
Trip coils of circuit breakers and interrupting devices in UFLS or UVLS systems.	No periodic maintenance specified	None.
Electromechanical trip or auxiliary devices	6 calendar years	Verify electrical operation of electromechanical trip and auxiliary devices
Unmonitored Control circuitry associated with protective functions	12 calendar years	Verify all paths of the control and trip circuits.
Control circuitry whose continuity and energization or ability to operate are monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

Table 2 – Alarming Paths In Tables 1-1 through 1-5, alarm attributes used to justify extended maximum maintenance intervals and/or reduced maintenance activities are subject to the following maintenance requirements		
Component Attributes	**Maximum Maintenance Interval**	**Activities**
Any alarm path through which alarms in Tables 1-1 through 1-5 are conveyed from the alarm origin to the location of corrective action, and not having all the attributes of the category below. Alarms are automatically reported within 24 hours of DETECTION to a location where corrective action can be taken.	When alarm producing device or system is verified	Verify that the alarm signals are conveyed to a location where corrective action can be taken.
Alarm Path with monitoring: The location where corrective action is taken receives an alarm within 24 hours for failure of any portion of the alarming path from the alarm origin to the location where corrective action can be taken.	No periodic maintenance specified	None.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

~~**Segment:** In this procedure, the term, "segment" is a grouping of Protection Systems or components from a single manufacturer, with common factors such that consistent performance is expected across the entire population of the segment, and shall only be defined for a population of 60 or more individual components.~~[4]

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of components included in each designated segment of the Protection System component population.
2. Maintain the components in each segment according to the time-based maximum allowable intervals established in ~~Table 1~~Tables 1-1through 1-5 until results of maintenance activities for the segment are available for a minimum of 30 individual components of the segment.
3. Document the maintenance program activities and results for each segment, including maintenance dates and countable events[5] for each included component.
4. Analyze the maintenance program activities and results for each segment to determine the overall performance of the segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System components and segments and/or description if any changes occur within the segment.
2. Perform maintenance on the greater of 5% of the components (addressed in the performance based PSMP) in each segment or 3 individual components within the segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each segment to determine the overall performance of the segment.
4. If the components in a Protection System segment maintained through a performance-based PSMP experience 4% or more countable events, develop, document, and

~~[4] Entities with smaller populations of component devices may aggregate their populations to define a segment and shall share all attributes of a single performance-based program for that segment.~~

[5] Countable events include any failure of a component requiring repair or replacement, any condition discovered during the verification activities in Table 1a through Table 1c which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure.

implement an action plan to reduce the countable events to less than 4% of the segment population within 3 years.

5. Using the prior year's data, determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

Implementation Plan for PRC-005-02

Standards Involved:

- Approval:
    - PRC-005-2 – Protection System Maintenance and Testing

- Retirements:
    - PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing
    - PRC-008-0 – Implementation and Documentation of Underfrequency Load Shedding
    - Equipment Maintenance Program
    - PRC-011-0 – Undervoltage Load Shedding System Maintenance and Testing
    - PRC-017-0 – Special Protection System Maintenance and Testing

Prerequisite Approvals:

- Revised definition of "Protection System"

Background:
The Implementation Plan reflects consideration of the following:

1. The requirements set forth in the proposed standard establish maximum allowable maintenance intervals for the first time. The established maximum allowable intervals may be shorter than those currently in use by some entities.
2. For entities using longer intervals than the maximum allowable intervals established in the proposed standard, it is unrealistic for those entities to be immediately in compliance with the new intervals. Further, entities should be allowed to become compliant in such a way as to facilitate a continuing maintenance program.
3. Entities that have previously been performing maintenance within the newly specified intervals may not have all the documentation needed to demonstrate compliance with all of the maintenance activities specified.

General Considerations:
Each Transmission Owner, Generator Owner, and Distribution Provider shall follow the protection system maintenance and testing program it used to perform maintenance and testing to comply with PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 (for the protection system components identified in PRC-005-2 Tables 1-1 through 1-5) until that Transmission Owner, Generator Owner or Distribution Provider meets initial compliance for maintenance of the same protection system component, in accordance with the phasing specified below.

For audits that are conducted during the time period when entities are modifying their existing protection system maintenance and testing programs to become compliant with the maintenance activities and intervals specified in PRC-005-2, each responsible entity must be prepared to identify:

- All of its applicable protection system components.
- For each component, whether maintenance of that component is still being addressed under PRC-005-1 or is being performed according toPRC-005-2.
- Evidence that each component has been maintained under the relevant requirements.

Retirement of Existing Standards:
The existing Standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 shall be retired upon regulatory approval of PRC-005-2.

Implementation Plan for Definition:
Protection System Maintenance Program – Entities shall use this definition when implementing any portions of R1, R2, R3, and R4 which use this defined term.

Implementation plan for Requirement R1:

- Entities shall be 100% compliant on the first day of the first calendar quarter twelve months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter six months following Board of Trustees adoption.

Implementation plan for Requirements R2, R3, and R4:

1. For Protection System Components with maximum allowable intervals of less than 1 year, as established in Tables 1-1 through 1-5:
    a. The entity shall be 100% compliant on the first day of the first calendar quarter 12 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 12 months following Board of Trustees adoption.

2. For Protection System Components with maximum allowable intervals 1 year or more, but 2 years or less, as established in Tables 1-1 through 1-5:
    a. The entity shall be 100% compliant on the first day of the first calendar quarter 2 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 2 calendar years following Board of Trustees adoption.

3. For Protection System Components with maximum allowable intervals of 6 years, as established in Tables 1-1 through 1-5:
    a. The entity shall be at least 30% compliant on the first day of the first calendar quarter 2 calendar years following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding two calendar years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 2 calendar years following Board of Trustees adoption.
    b. The entity shall be at least 60% compliant on the first day of the first calendar quarter 4 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 4 calendar years following Board of Trustees adoption.
    c. The entity shall be 100% compliant on the first day of the first calendar quarter 6 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 6 calendar years following Board of Trustees adoption.

4. For Protection System Components with maximum allowable intervals of 12 years, as established in Tables 1-1 through 1-5:
    a. The entity shall be at least 30% compliant on the first day of the first calendar quarter 4 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 4 calendar years following Board of Trustees adoption.
    b. The entity shall be at least 60% compliant on the first day of the first calendar quarter following 8 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 8 calendar years following Board of Trustees adoption.
    c. The entity shall be 100% compliant on the first day of the first calendar quarter 12 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 12 calendar years following Board of Trustees adoption.

Applicability:
This standard applies to the following functional entities:

- Transmission Owners
- Generator Owners
- Distribution Providers

NERC
NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

~~Draft~~ Implementation Plan for PRC-005-02

Standards Involved:

- Approval:
  - PRC-005-2 – Protection System Maintenance and Testing

- Retirements:
  - PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing
  - PRC-008-0 – Implementation and Documentation of Underfrequency Load Shedding
  - Equipment Maintenance Program
  - PRC-011-0 – Undervoltage Load Shedding System Maintenance and Testing
  - PRC-017-0 – Special Protection System Maintenance and Testing

Prerequisite Approvals:

- Revised definition of "Protection System"

Background:

~~In developing the implementation plan, the Standard Drafting Team considered~~The Implementation Plan reflects consideration of the following:

1. The requirements set forth in the proposed standard establish maximum allowable maintenance intervals for the first time. The established maximum allowable intervals may be shorter than those currently in use by some entities.
2. For entities using longer intervals than the maximum allowable intervals established in the proposed standard, it is unrealistic for those entities to be immediately in compliance with the new intervals. Further, entities should be allowed to become compliant in such a way as to facilitate a continuing maintenance program.
3. Entities that have previously been performing maintenance within the newly specified intervals may not have all the documentation needed to demonstrate compliance with all of the maintenance activities specified.

General Considerations:

Each Transmission Owner, Generator Owner, and Distribution Provider shall follow the protection system maintenance and testing program it used to perform maintenance and testing to comply with PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 (for the protection system components identified in PRC-005-2 ~~Table 1a~~Tables 1-1 through 1-5) until that Transmission Owner, Generator Owner or Distribution Provider meets initial compliance for maintenance of the same protection system component, in accordance with the phasing specified below.

For audits that are conducted during the time period when entities are modifying their existing protection system maintenance and testing programs to become compliant with the maintenance activities and intervals specified in PRC-005-2, each responsible entity must be prepared to identify:

- All of its applicable protection system components.
- For each component, whether maintenance of that component is still being addressed under PRC-005-1 or ~~has been moved under PRC~~is being performed according toPRC-005-2.
- Evidence that each component has been maintained under the relevant requirements.

Retirement of Existing Standards:
The existing Standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 shall be retired upon regulatory approval of PRC-005-2.

Implementation Plan for Definition:
Protection System Maintenance Program – Entities shall use this definition when implementing any portions of R1, R2, R3, and R4 which use this defined term.

Implementation plan for Requirement R1:

- Entities shall be 100% compliant on the first day of the first calendar quarter ~~three~~twelve months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter six months following Board of Trustees adoption.

Implementation plan for Requirements R2, R3, and R4:

1. For Protection System Components with maximum allowable intervals of less than 1 year, as established in ~~Table 1a,~~ Tables 1-1 through 1-5:
   a. The entity shall be 100% compliant on the first day of the first calendar quarter 12 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 12 months following Board of Trustees adoption.

2. For Protection System Components with maximum allowable intervals 1 year or more, but 2 years or less, as established in ~~Table 1a,~~ Tables 1-1 through 1-5:
   a. The entity shall be 100% compliant on the first day of the first calendar quarter 2 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 2 calendar years following Board of Trustees adoption.

3. For Protection System Components with maximum allowable intervals of 6 years, as established in ~~Table 1a,~~ Tables 1-1 through 1-5:
   a. The entity shall be at least 30% compliant on the first day of the first calendar quarter 2 calendar years following applicable regulatory approval~~,~~ (or, for generating plants with scheduled outage intervals exceeding two calendar years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 2 calendar years following Board of Trustees adoption.
   b. The entity shall be at least 60% compliant on the first day of the first calendar quarter 4 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 4 calendar years following Board of Trustees adoption.
   c. The entity shall be 100% compliant on the first day of the first calendar quarter 6 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 6 calendar years following Board of Trustees adoption.

4. For Protection System Components with maximum allowable intervals of 12 years, as established in ~~Table 1a,~~ Tables 1-1 through 1-5:
   a. The entity shall be at least 30% compliant on the first day of the first calendar quarter 4 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 4 calendar years following Board of Trustees adoption.
   b. The entity shall be at least 60% compliant on the first day of the first calendar quarter following 8 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 8 calendar years following Board of Trustees adoption.
   c. The entity shall be 100% compliant on the first day of the first calendar quarter 12 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 12 calendar years following Board of Trustees adoption.

Applicability:
This standard applies to the following functional entities:

- Transmission Owners
- Generator Owners
- Distribution Providers

Unofficial Comment Form for 3rd Draft of PRC-005-2 – Protection System Maintenance [Project 2007-17]

Please **DO NOT** use this form to submit comments on the 3rd draft of the standard for Protection System Maintenance and Testing. Comments must be submitted by **December 17, 2010**. If you have questions please contact Al McMeekin at al.mcmeekin@nerc.net or by telephone at 803-530-1963.

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Background Information:

The Protection System Maintenance and Testing Standard Drafting Team (PSMT SDT) has made substantial changes to the third posting of PRC-005-2 based on comments received from the industry. The changes include:

- Adding more definitions of terms used in the body of the standard.
- Revisions to the standard and tables to remove complexity.
- Revisions to the implementation period.
- Revisions to the Supplemental Reference and the FAQ documents.
- Revisions to the Measures, Time Horizons, Violation Risk Factors (VRFs) and Violation Security Levels (VSLs).

The PSMT SDT would like to receive industry comments on this standard.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. The SDT has restructured the tables to improve clarity, but did not appreciably change the content. Do you agree that the restructured tables are clearer? If not, please provide specific suggestions for improvement.

   ☐ Yes
   ☐ No
   Comments:

2. The SDT has modified the VSLs, VRFs and Time Horizons with this posting. Do you agree with the changes? If not, please provide specific suggestions for improvement.

   ☐ Yes
   ☐ No
   Comments:

3. The SDT has provided the “Supplementary Reference” document to provide supporting discussion for the Requirements within the standard. Do you have any specific suggestions for improvements?

   ☐ Yes

   ☐ No

   Comments:

4. The SDT has provided the “Frequently-Asked Questions” (FAQ) document to address anticipated questions relative to the standard. Do you have any specific suggestions for improvements?

   ☐ Yes

   ☐ No

   Comments:

5. If you have any other comments on this Standard that you have not already provided in response to the prior questions, please provide them here.

NERC Protection System Maintenance Standard PRC-005-2

FREQUENTLY ASKED QUESTIONS - Practical Compliance and Implementation

November 17, 2010

Informative Annex to Standard PRC-005-2

Prepared by the

Protection System Maintenance and Testing Standard Drafting Team

Table of Contents

Introduction

The following is a draft collection of questions and answers that the PSMT SDT believes could be helpful to those implementing NERC Standard PRC-005-2 Protection System Maintenance. As the draft standard proceeds through development, this FAQ document will be revised, including responses to key or frequent comments from the posting process. The FAQ will be organized at a later time during the development of the draft Standard.

This FAQ document will support both the Standard and the associated Technical Reference document.

Terms Used in PRC-005-2

Frequently Asked Questions

I General FAQs:

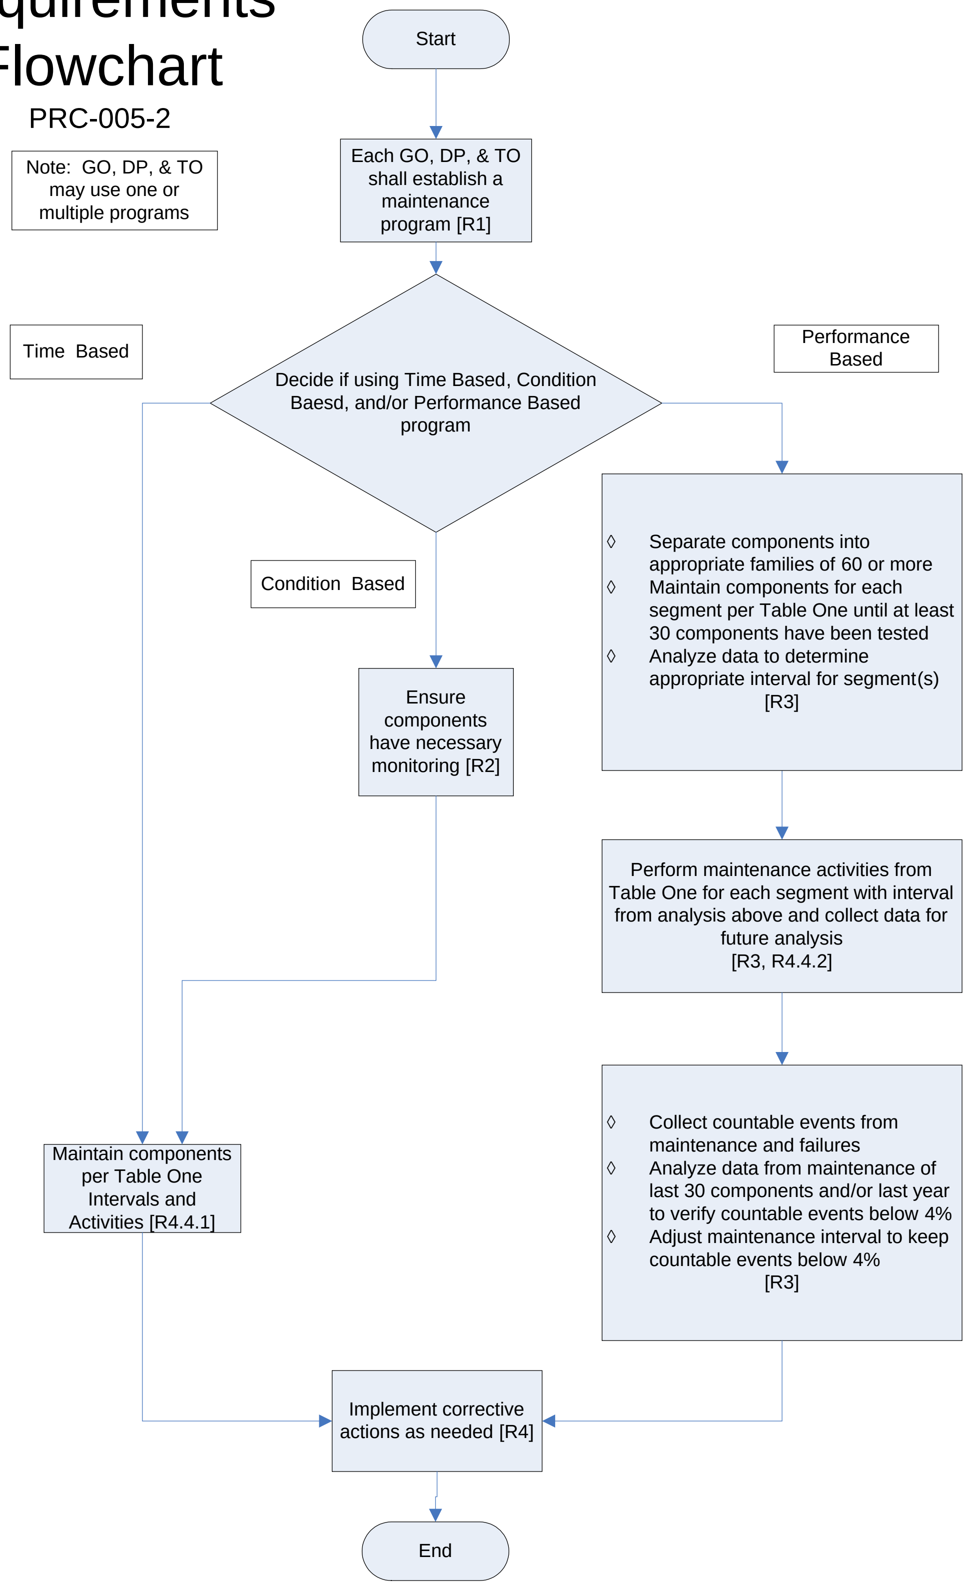
1. **The standard seems very complicated, and is difficult to understand. Can it be simplified?**

   Because the standard is establishing parameters for condition-based Maintenance (R2) and performance-based Maintenance (R3) in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to and perform ONLY time-based maintenance according to the unmonitored rows of the Tables. If an entity then wishes to take advantage of monitoring on its Protection System components and its available lengthened time intervals then it may, as long as the component has the listed monitoring attributes. If an entity wishes to use historical performance of its Protection System components to perform performance-based Maintenance, then R3 applies.

   Please see the following diagram, which provides a “flow chart” of the standard.

Requirements Flowchart

PRC-005-2



II Group by Type of Protection System Component:

1. All Protection System Components

A. Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this standard?

No. As stated in Requirement R1, this standard covers protective relays that use measurements of voltage, current and/or phase angle to determine anomalies and to trip a portion of the BES. Reclosers, reclosing relays, closing circuits and auto-restoration schemes are used to cause devices to close as opposed to electrical-measurement relays and their associated circuits that cause circuit interruption from the BES; such closing devices and schemes are more appropriately covered under other NERC Standards. There is one notable exception: if a Special Protection System incorporates automatic closing of breakers, the related closing devices are part of the SPS and must be tested accordingly.

B. Why does PRC-005-2 not specifically require maintenance and testing procedures as reflected in the previous standard, PRC-005-1?

PRC-005-1 does not require <u>detailed</u> maintenance and testing procedures, but instead requires <u>summaries</u> of such procedures, and is not clear on what is actually required. PRC-005-2 requires a documented maintenance program, and is focused on establishing requirements rather than prescribing methodology to meet those requirements. Between the activities identified in the tables 1-1 through 1-5 and Table 2 (collectively the "Tables"), and the various components of the definition established for a "Protection System Maintenance Program", PRC-005-2 establishes the activities and time-basis for a Protection System Maintenance Program to a level of detail not previously required.

2. Protective Relays

A. How do I approach testing when I have to upgrade firmware of a microprocessor relay?

The entity should ensure that the relay continues to function properly after implementation of firmware changes. Some entities may have a R&D department that might routinely run acceptance tests on devices with firmware upgrades before allowing the upgrade to be installed. Other entities may rely upon the vigorous testing of the firmware OEM. An entity has the latitude to install devices and/or programming that they believe will perform to their satisfaction. If an entity should choose to perform the maintenance activities specified in the Tables following a firmware upgrade then they may, if they choose, reset the time clock on that set of maintenance activities so that they would not have to repeat the maintenance on its regularly scheduled cycle. (However, for simplicity in maintenance schedules, some entities may choose to not reset this time clock; it is merely a suggested option.)

B. Please clarify what is meant by restoration in the definition of maintenance.

The description of "Restoration" in the definition of a Protection System Maintenance Program, addresses corrective activities necessary to assure that the component is returned to working order following the discovery of its failure or malfunction. The Maintenance Activities specified in the Tables do not present any requirements related to Restoration; R4.3 of the standard does require that the entity "initiate any necessary activities to correct unresolved maintenance correctable issues". Some examples of restoration (or correction of maintenance-correctable issues) include, but are not limited to, replacement of capacitors in distance relays to bring them to working order; replacement of relays, or other Protection System components, to bring the Protection System to working order; upgrade of electro-mechanical or solid-state protective relays to micro-processor based relays following the discovery of failed components. Restoration, as used in this context is not to be confused with Restoration rules as used in system operations. Maintenance activity necessarily includes both the detection of problems and the repairs needed to eliminate those problems. This standard does not identify all of the Protection System problems that must be detected and eliminated, rather it is the intent of this standard that an entity determines the necessary working order for their various devices and keeps them in working order. If an equipment item is repaired or replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work

C. If I upgrade my old relays then do I have to maintain my previous equipment maintenance documentation?

If an equipment item is repaired or replaced then the entity can restart the maintenance-activity-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements. The requirements in the standard are intended to ensure that an entity has a maintenance plan and that the entity adheres to minimum activities and maximum time intervals. The documentation requirements are intended to help an entity demonstrate compliance. For example, saving the dates and records of the last two maintenance activities is intended to demonstrate compliance with the interval. Therefore, if you upgrade or replace equipment then you still must maintain the documentation for the previous equipment, thus demonstrating compliance with the time interval requirement prior to the replacement action.

D. What is meant by "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed mostly towards microprocessor based relays.

For relay maintenance departments that choose to test microprocessor based relays in the same manner as electro-mechanical relays are tested, the testing process sometimes requires that some specific functions be disabled. Later tests might enable the functions previously disabled but perhaps still other functions or logic statements were then masked out. It is imperative that, when the relay is placed into service, the settings in the relay be the settings that were intended to be in that relay or as the Standard states "…settings are as specified."

Many of the microprocessor based relays available today have software tools which provide this functionality and generate reports for this purpose.

For evidence or documentation of this requirement a simple recorded acknowledgement that the settings were checked to be as specified is sufficient.

The drafting team was careful not to require "…that the relay settings be correct…" because it was believed that this might then place a burden of proof that the specified settings would result in the correct intended operation of the interrupting device. While that is a noble intention, the measurable proof of such a requirement is immense. The intent is simply to check that the settings in the relay match the settings specified to those placed into the relay.

E. Are electromechanical relays included in the "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed towards the application of protection related functions of microprocessor based relays. Electromechanical relays require calibration verification by voltage and/or current injection, and thus the settings are verified during calibration activity. In the example of a time-overcurrent relay, a minor deviation in time dial, versus the settings, may be acceptable as long as the relay calibration is within accepted tolerances at the injected current amplitudes. A major deviation may require further investigation, as it could indicate a problem with the relay or an incorrect relay style for the application.

F. I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?

This standard addresses only devices "that are applied on, or are designed to provide protection for the BES." Protective relays, providing only the functions mentioned in the question, are not included.

G. I use my protective relays for fault and disturbance recording, collecting oscillographic records and event records via communications for fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?

For relays used only as disturbance monitoring equipment, the NERC standard PRC-018-1 R3 & R6 states the maintenance requirements, and is being addressed by a Standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays "that are applied on, or are designed to provide protection for the BES," this standard applies, even if they also perform DME functions.

H. We have a number of installations where we have changed our Protection System components. Some of the changes were upgrades, but others were simply system rating changes that merely required taking relays "out-of-service". What are our responsibilities when it comes to "out-of-service" devices?

Assuming that your system up-rates, upgrades and overall changes meet any and all other requirements and standards then the requirements of PRC-005-2 are simple – if the Protection system component performs a Protection system function then it must be maintained. If the component no longer performs Protection System functions than it does not require maintenance activities under the Tables of PRC-005-2. While many entities might physically remove a component that is no longer needed there is no requirement in PRC-005-2 to remove such component(s). Obviously, prudence would dictate that an "out-of-service" device is truly made inactive. There are no record requirements listed in PRC-005-2 for Protection System components not used.

I. While performing relay testing of a protective device on our Bulk Electric System it was discovered that the protective device being tested was either broken or out of calibration.

Does this satisfy the relay testing requirement even though the protective device tested bad, and may be unable to be placed back into service?

Yes, PRC-005-2 requires entities to perform relay testing on protective devices on a given maintenance cycle interval. By performing this testing, the entity has satisfied PRC-005-2 requirement although the protective device may be unable to be returned to service under normal calibration adjustments. R4.3 states (the entity must):
The entity must assure either that the components are within acceptable parameters at the conclusion of the maintenance activities or initiate any necessary activities to correct unresolved maintenance correctable issues.

J. If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R4.3) (in essence) state that the entity assure the components are within the owner's acceptable operating parameters, if not then actions must be initiated to correct the deviance. The type of corrective activity is not stated; however it could include repairs or replacements. Documentation is always a necessity ("*If it is not documented then it wasn't done!*")
Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

K. What calibration tolerance should be applied on electromechanical relays?

Each entity establishes their own acceptable tolerances when applying protective relaying on their system. For some Protection System components, adjustment is required to bring measurement accuracy within the parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

L. What is meant by "verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System?"

Any input or output that "affects the tripping" of the breaker is included in the scope of I/O to be verified. By "affects the tripping" one needs to realize that sometimes there are more Inputs and Outputs than simply the output to the trip coil. Many important protective functions include things like Breaker Fail Initiation, Zone Timer Initiation and sometimes even 52a/b contact inputs are needed for a protective relay to correctly operate.

Each input should be "picked up" or "turned on and off" and verified as changing state by the microprocessor of the relay. Each output should be "operated" or "closed and opened" from the microprocessor of the relay and the output should be verified to change state on the output terminals of the relay.

Each input detector on a component that is needed for a protective function and each output action from a component that is needed for a protective function needs to be tested.

In short, if an entity designed a scheme into the protective functions then that scheme needs to be tested.

3. **Voltage and Current Sensing Device Inputs to Protective Relays**

A. **What is meant by "…verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" Do we need to perform ratio, polarity and saturation tests every few years?**

No. You must verify that the protective relay is receiving the expected values from the voltage and current sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. While some examples follow, these are not intended to represent an all-inclusive list; technology advances and ingenuity should not be excluded from making comparisons and verifications:

- Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.
- Compare the individual phase secondary values at the relay panel (with additional testing on the panel wiring to ensure that the values arrive at those relays) with the other phases, and verify that residual currents are within expected bounds
- Observe all three phase currents and the residual current at the relay panel with an oscilloscope, observing comparable magnitudes and proper phase relationship, with additional testing on the panel wiring to ensure that the values arrive at the relays.
- Compare the values, as determined by the questioned relay (such as, but not limited to, a query to the microprocessor relay), to another protective relay monitoring the same line, with currents supplied by different CT's.
- Compare the secondary values, at the relay with values measured by test instruments (such as, but not limited to multi-meters, voltmeter, clamp-on ammeters, etc) and verified by calculations and known ratios to be the values expected. For example a single PT on a 100KV bus will have a specific secondary value that when multiplied by the PT ratio arrives at the expected bus value of 100KV.
- Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.
- Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

The point of the verification procedure is to ensure that all of the individual components are functioning properly; and that, an ongoing proactive procedure is in place to re-check the various components of the protective relay measuring systems.

B. **The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?**

Since these inputs are verified at commissioning, maintenance verification requires ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0.

These quantities also may be verified by use of oscillographic records for connected microprocessor relays as recorded during system disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known fault locations.

C. Is wiring insulation or hi-pot testing required by this Maintenance Standard?

No, wiring insulation and equipment hi-pot testing are not specifically required by the Maintenance Standard. However, if the method of verifying CT and PT inputs to the relay involves some other method than actual observation of current and voltage transformer secondary inputs to the relay, it might be necessary to perform some sort of cable integrity test to verify that the instrument transformer secondary signals are actually making it to the relay and not being shunted off to ground. For instance, you could use CT excitation tests and PT turns ratio tests and compare to baseline values to verify that the instrument transformer outputs are acceptable. However, to conclude that these acceptable transformer instrument output signals are actually making it to the relay inputs, it also would be necessary to verify the insulation of the wiring between the instrument transformer and the relay.

D. My plant generator and transformer relays are electromechanical and do not have metering functions as do microprocessor based relays. In order for me to compare the instrument transformer inputs to these relays to the secondary values of other metered instrument transformers monitoring the same primary voltage and current signals, it would be necessary to temporarily connect test equipment like voltmeters and clamp on ammeters to measure the input signals to the relays. This practice seems very risky and a plant trip could result if the technician were to make an error while measuring these current and voltage signals. How can I avoid this risk? Also, what if no other instrument transformers are available which monitor the same primary voltage or current signal?

Comparing the input signals to the relays to the outputs of other independent instrument transformers monitoring the same primary current or voltage is just one method of verifying the instrument transformer inputs to the relays but is not required by the standard. Plants can choose how to best manage their risk. If online testing is deemed too risky, offline tests such as, but not limited to, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately “verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …” while eliminating the risk of tripping an in service generator or transformer. Similarly, this same offline test methodology can be used to verify the relay input voltage and current signals to relays when there are no other instrument transformers monitoring available for purposes of signal comparison.

4. Protection System Control Circuitry

A. Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?

Yes, provided the entire Protective System is tested within the individual components' maximum allowable testing intervals.

B. The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?

Requirements in PRC-005-2 are intended to verify the integrity of tripping circuits, including the breaker trip coil, as well as the presence of auxiliary supply (usually a battery) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-2 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

C. How do I test each dc Control Circuit path, as established in Table 1-5 "Protection System Control Circuitry (Trip coils and auxiliary relays)"?

Table 1-5 specifies that each breaker trip coil, auxiliary relay, and lockout relay must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as fault clearing.

D. What does this standard require for testing an Auxiliary Tripping Relay?

Table 1 requires that the trip test must verify that the auxiliary tripping relay(s) and/or lockout relay(s) operate(s) electrically and that their trip output(s) perform as expected. Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this standard, to be checked.

E. What does a functional (or operational) trip test include?

An operational trip test must be performed on a trip device. Each control circuit path that produces a trip signal must be verified; this includes trip coils, auxiliary tripping relays, lockout relays, and communications-assisted-trip schemes.

A trip test may be an overall test that verifies the operation of the entire trip scheme at once, or it may be several tests of the various portions that make up the entire trip path, provided that testing of the various portions of the trip scheme verifies all of the portions, including parallel paths, and overlaps those portions.

A circuit breaker or other interrupting device needs to be trip tested at least once per trip coil.

Discrete-component auxiliary relays and lock-out relays must be verified by trip test. The trip test must verify that the auxiliary or lock-out relay operates electrically and that the relay's trip output(s) change(s) state. Software latches or control algorithms, including trip logic processing implemented as programming component such as a microprocessor relay that take the place of (conventional) discrete component auxiliary relays or lock-out relays do not have to be routinely trip tested.

Normally-closed auxiliary contacts from other devices (for example, switchyard-voltage-level disconnect switches, interlock switches, or pressure switches) which are in the breaker trip path do not need to be tested.

F. Is a Sudden Pressure Relay an Auxiliary Tripping Relay?

No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63, and is excluded from the Standard because it does not utilize voltage and/or current measurements to determine anomalies. Devices that use anything other than electrical detection means are excluded.

G. The standard specifically mentions Auxiliary and Lock-out relays; what is an Auxiliary Tripping Relay?

An auxiliary relay, IEEE Device Number 94, is described in IEEE Standard C37.2-2008 as “A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed.”

H. What is a Lock-out Relay?

A lock-out relay, IEEE Device Number 86, is described in IEEE Standard C37.2 as “A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely.”

I. My mechanical device does not operate electrically and does not have calibration settings; what maintenance activities apply?

You must conduct a test(s) to verify the integrity of the trip circuit. This standard does not cover circuit breaker maintenance or transformer maintenance. The standard also does not cover testing of devices such as sudden pressure relays (63), temperature relays (49), and other relays which respond to mechanical parameters rather than electrical parameters.

5. Station dc Supply

A. What constitutes the station dc supply as mentioned in the definition of Protective System?

The station direct current (dc) supply normally consists of two components: the battery charger and the station battery itself. There are also emerging technologies that provide a source of dc supply that does not include either a battery or charger.

Battery Charger - The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

Station Battery - Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1.

Emerging Technologies - Station dc supplies are currently being developed that use other energy storage technologies beside the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new the maintenance activities for these station dc supplies may change over time.

B. In the Maintenance Activities for station dc supply in Table 1, what do you mean by "continuity"?

Because the Standard pertains to maintenance not only of the station battery, but also the whole station dc supply, continuity checks of the station dc supply are required. "Continuity" as used in Table 1 refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal, otherwise there is no way of determining that a station battery is available to supply dc current to the station.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path the battery set will not be available for service.

C. Why is it necessary to verify the continuity of the dc supply?

In the event of the loss of the ac source or battery charger, the battery must be capable of supplying dc current, both for continuous dc loads and for tripping breakers and switches. Without continuity, the battery cannot perform this function.

If the battery charger is not sized to handle the maximum dc current required to operate the protective systems, it is sized only to handle the constant dc load of the station and the charging current required to bring the battery back to full charge following a discharge. At those stations, the battery charger would not be able to trip breakers and switches if the battery experiences loss of continuity.

At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

- ◊ Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.
- ◊ Loss of electrical continuity of the station battery will cause, regardless of the battery charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional 1 to 2 second delay to switch from a low substation dc load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed which could violate system performance standards.

D. How do you verify continuity of the dc supply?

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery unless the battery charger is taken out of service. At that time a break in the continuity of the station battery current path will be revealed because there will be no voltage on the station dc circuitry.

Although the Standard prescribes what must be done during the maintenance activity it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery. These are not the only possible methods, simply a sampling of some methods:

- ◊ One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.
- ◊ A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the various dc-supplied equipment in the station should be considered before using this approach.
- ◊ Manufacturers of microprocessor controlled battery chargers have developed methods for their equipment to periodically (or continuously) test for battery continuity. For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc load can be measured to confirm continuity.
- ◊ Applying test current (as in an ohmic testing device) will provide a current that when measured elsewhere in the string, will prove that the circuit is continuous.

No matter how the electrical continuity of a battery set is verified it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1 to insure that the station dc supply has a path that can provide the required current to the Protection System at all times.

E. When should I check the station batteries to see if they have sufficient energy to perform as designed?

The answer to this question depends on the type of battery (valve regulated lead-acid, vented lead acid, or nickel-cadmium), the maintenance activity chosen, and the type of time based monitoring level selected.

For example, if you have a Valve Regulated Lead-Acid (VRLA) station battery, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than every three months. While this interval might seem to be quite short, keep in mind that the 3 month interval is consistent with IEEE guidelines for VRLA batteries; this interval provides an accumulation of data that better shows when a VRLA battery is no longer capable of its design capacity.

If, for a VRLA station battery, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every 3 calendar years.

F. Why in Table 1 are there two Maintenance Activities with different Maximum Maintenance Intervals listed to verify that the station battery can perform as designed?

The two acceptable methods for proving that a station battery can perform as designed are based on two different philosophies. The first activity requires a capacity discharge test of the entire battery set to verify that degradation of one or several components (cells) in the set has not deteriorated to a point where the total capacity of the battery system falls below its designed rating. The second maintenance activity requires tests and evaluation of the internal ohmic measurements on each of the individual cells/units of the battery set to determine that each component can perform as designed and therefore the entire battery set can be verified to perform as designed.

The maximum maintenance interval for discharge capacity testing is longer than the interval for testing and evaluation of internal ohmic cell measurements. An individual component of a battery set may degrade to an unacceptable level without causing the total battery set to fall below its designed rating under capacity testing. However, since the philosophy behind internal ohmic measurement evaluation is based on the fact that each battery component must be verified to be able to perform as designed, the interval for verification by this maintenance activity must be shorter to catch individual cell/unit degradation. It should be noted that even if a battery unit is composed of multiple cells the ohmic test can still be accomplished. The data produced becomes trending data on the multi-cell unit instead of trending individual cells.

G. What is the justification for having two different Maintenance Activities listed in Table 1 to verify that the station battery can perform as designed?

IEEE Standards 450, 1188, and 1106 for vented lead-acid, valve-regulated lead-acid (VRLA), and nickel-cadmium batteries, respectively (which together are the most commonly used substation batteries on the BES) go into great detail about capacity testing of the entire battery set to determine that a battery can perform as designed.

The first maintenance activity listed in Table 1 for verifying that a station battery can perform as designed uses maximum maintenance intervals for capacity testing that were designed to align with the IEEE battery standards. This maintenance activity is applicable for vented lead-acid, valve-regulated lead-acid, and nickel-cadmium batteries.

The second maintenance activity listed in Table 1 for verifying that a station battery can perform as designed uses maximum maintenance intervals for evaluating internal ohmic measurements in relation to their baseline measurements that are based on industry experience, EPRI technical reports and application guides, and the IEEE battery standards. By evaluating the internal ohmic measurements for each cell and comparing that measurement to the cell's baseline ohmic measurement (taken at the time of the battery set's acceptance capacity test), low-capacity cells can be identified and eliminated to keep the battery set capable of performing as designed. This maintenance activity is applicable only for vented lead-acid and VRLA batteries; this trending activity has not shown to be effective for NiCd batteries thus the only choices for NiCd batteries are the performance tests (see applicable IEEE guideline for specifics on performance tests). It should be noted that even if a battery unit is composed of multiple cells the ohmic test can still be accomplished. The data produced becomes trending data on the multi-cell unit instead of trending individual cells.

H. Why in Table 1 of PRC-005-2 is there a maintenance activity to inspect the structural intergrity of the battery rack?

The three IEEE standards (1188, 450, and 1106) for VRLA, vented lead-acid, and nickel-cadmium batteries all recommend that as part of any battery inspection the battery rack should be inspected. The purpose of this inspection is to verify that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity. Because the battery rack is specifically designed for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

I. What is required to comply with the "Unintentional Grounds" requirement?

In most cases, the first ground that appears on a battery is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many systems are designed to operate favorably under some unintentional DC ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on detected unintentional DC grounds. The standard merely requires that a check be made for the existence of Unintentional DC Grounds. Obviously a "check-off" of some sort will have to be devised by the inspecting entity to document that a check is routinely done for Unintentional DC Grounds.

J. Where the standard refers to "all cells" is it sufficient to have a documentation method that refers to "all cells" or do we need to have separate documentation for every cell? For example to I need 60 individual documented check-offs for good electrolyte level or would a single check-off per bank be sufficient?

A single check-off per battery bank is sufficient for documentation, as long as the single check-off attests to checking all cells/units.

K. Does this standard refer to Station batteries or all batteries, for example Communications Site Batteries?

This standard refers to Station Batteries. The drafting team does not believe that the scope of this standard refers to communications sites. The batteries covered under PRC-005-2 are the batteries that supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System. The SDT believes that a loss of power to the communications systems at a remote site would cause the communications systems associated with protective relays to alarm at the substation. At this point the corrective actions can be initiated.

L. My VRLA batteries have multiple-cells within an individual battery jar (or unit); how am I expected to comply with the cell-to-cell ohmic measurement requirements on these units that I cannot get to?

The values that are measured at all available terminals will produce results that can be tracked. Thus the trended results become the results of a unit instead of an individual cell. Bad units (regardless of the number of cells per unit) will result in the eventual repair or replacement of multiple cells even if only a single cell actually went bad. Cell-to-cell tests can equate to unit-to-unit tests or jar-to-jar tests. If there is such a thing as a single unit that contains the entire battery for the facility but only brings out the positive and negative posts (as in a car battery) then the testing across these only two available posts will produce usable trending test data.

6. Protection System Communications Equipment

A. What are some examples of mechanisms to check communications equipment functioning?

For unmonitored Protection Systems, various types of communications systems will have different facilities for on-site integrity checking to be performed at least every three months during a substation visit. Some examples are, but not limited to:

◊ On-off power-line carrier systems can be checked by performing a manual carrier keying test between the line terminals, or carrier check-back test from one terminal.
◊ Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing for a loss-of-guard indication or alarm. For frequency-shift power-line carrier systems, the guard signal level meter can also be checked.
◊ Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
◊ Digital communications systems typically have a data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

For monitored Protection Systems, various types of communications systems will have different facilities for monitoring the presence of the communications channel, and activating alarms that can be monitored remotely. Some examples are, but not limited to:

◊ On-off power-line carrier systems can be shown to be operational by automated periodic power-line carrier check-back tests, with remote alarming of failures.
◊ Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
◊ Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
◊ Digital communications systems can activate remotely monitored alarms for data reception loss or data error indications.
◊ Systems can be queried for the data error rates.

For the highest degree of monitoring of Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays.

◊ In many communications systems signal quality measurements including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.
◊ Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

B. What is needed for the 3-month inspection of communications-assisted trip scheme equipment?

The 3-month inspection applies to unmonitored equipment. An example of compliance with this requirement might be, but is not limited to:

With each site visit, check that the equipment is free from alarms, check any metered signal levels, and that power is still applied. While this might be explicit for a particular type of equipment (i.e., FSK equipment), the concept should be that the entity verify that the communications equipment that is used in a Protection System is operable through a cursory inspection and site visit. This site visit can be eliminated on this particular example if the FSK equipment had a monitored alarm on Loss of Guard.

C. Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a communications system?

This equipment is presently classified as being part of the Protection System Control Circuitry and tested per the portions of Table 1 applicable to Protection System Control Circuitry rather than those portions of the table applicable to communications equipment.

D. In Table 1-2, the Maintenance Activities section of the Protective System Communications Equipment and Channels refers to the quality of the channel meeting "performance criteria". What is meant by performance criteria?

Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally an alarm will be indicated. For unmonitored systems this alarm will probably be on the panel. For monitored systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each protective system communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm. Following are some examples of protective system communications channel performance measuring:

- ◊ For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm.
- ◊ An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use check-back testing to determine channel performance. A predetermined signal sequence is sent to the remote end and the remote end decodes this signal and sends a signal sequence back. If the sending end receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.
- ◊ Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.

◊ Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase information over the communications path to determine if the fault is located in the protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These limits are determined and set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This standard does not state what the performance criteria will be - it just requires that the entity establish nominal criteria so protective system channel monitoring can be performed.

7. UVLS and UFLS Relays that Comprise a Protection System Distributed Over the Power System

A. We have an Under Voltage Load Shedding (UVLS) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this standard?

The situation as stated indicates that the tripping action was intended to prevent low distribution voltage to a specific load from a transmission system that was intact except for the line that was out of service, as opposed to preventing cascading outage or transmission system collapse.

This Standard is not applicable to this UVLS.

B. We have a UFLS scheme that sheds the necessary load through distribution-side circuit breakers and circuit reclosers. Do the trip-test requirements for circuit breakers apply to our situation?

No. Distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential Lock-Out Relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this standard.

C. What does “distributed over the power system” mean?

This refers to the common practice of applying UFLS on the distribution system, with each UFLS individually tripping a relatively low value of load. Therefore, the program is implemented via a large number of individual UFLS components performing independently, and the failure of any individual component to perform properly will have a minimal impact on the effectiveness of the overall UFLS program. Some UVLS systems are applied similarly.

8. SPS or Relay Sensing for Centralized UFLS or UVLS

A. Do I have to perform a full end-to-end test of a Special Protection System?

No. All portions of the SPS need to be maintained, and the portions must overlap, but the overall SPS does not need to have a single end-to-end test.

B. What about SPS interfaces between different entities or owners?

All SPS owners should have maintenance agreements that state which owner will perform specific tasks. As in all of the Protection System requirements, SPS segments can be tested individually thus minimizing the need to accommodate complex maintenance schedules.

C. What do I have to do if I am using a phasor measurement unit (PMU) as part of a Protection System or Special Protection System?

Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or Special Protection System (as opposed to a monitoring task) must be verified as a component in a Protection System.

D. How do I maintain a Special Protection System or Relay Sensing for Centralized UFLS or UVLS Systems?

Since components of the SPS, UFLS, or UVLS are the same types of components as those in Protection Systems then these components should be maintained like similar components used for other Protection System functions. In many cases the devices for SPS, UFLS and UVLS are also used for other protective functions. The same maintenance activities apply with the exception that distributed systems (UFLS and UVLS) have fewer dc supply and control circuitry maintenance activity requirements.

For the testing of the output action, verification may be by breaker tripping, but may be verified in overlapping segments. For example an SPS that trips a remote circuit breaker might be tested by testing the various parts of the scheme in overlapping segments. Another method is to document the real-time tripping of an SPS scheme should that occur. Forced trip tests of circuit breakers (etc) that are a part of distributed UFLS or UVLS schemes are not required

E. What does "centralized" mean?

This refers to the practice of applying sensing units at many locations over the system, with all these components providing intelligence to an analytical system which then directs action to address a detected condition. In some cases, this action may not take place at the same location as the sensing units. This approach is often applied for complex SPS, and may be used for UVLS (and perhaps even with UFLS) where necessary to address the conditions of concern.

III Group by Type of BES Facility:

1. All BES Facilities

A. What, exactly, is the BES, or Bulk Electric System?

BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms Used in Reliability Standards, and is not being modified within this draft Standard.

NERC's approved definition of Bulk Electric System is:

> As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only load with one transmission source are generally not included in this definition.

Each Regional Entity implements a definition of the Bulk Electric System that is based on this NERC definition, in some cases, supplemented by additional criteria. These regional definitions have been documented and provided to FERC as part of a *June 16, 2007 Informational Filing*.

2. Generation

A. Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, and generator connected station auxiliary transformer to meet the requirements of this Maintenance Standard.

Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays
- Volts-per-hertz relays
- Negative sequence overcurrent relays
- Over voltage and under voltage protection relays
- Stator-ground relays
- Communications-based protection systems such as transfer-trip systems
- Generator differential relays
- Reverse power relays
- Frequency relays
- Out-of-step relays
- Inadvertent energization protection
- Breaker failure protection

For generator step up or generator-connected station auxiliary transformers, operation of any the following associated protective relays frequently would result in a trip of the generating unit and, as such, would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

A loss of a system-connected station auxiliary transformer could result in a loss of the generating plant if the plant was being provided with auxiliary power from that source, and this auxiliary transformer may directly affect the ability to start up the plant and to connect the plant to the system. Thus, operation of any of the following relays associated with system-connected station auxiliary transformers would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of the those loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program even if a trip of these devices might eventually result in a trip of the generating unit. For example, a thermal overcurrent trip on the motor of a coal-conveyor belt could eventually lead to the tripping of the generator, but it does not cause the trip.

3. Transmission

A. Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

IV Group by Type of Maintenance Program:

1. All Protection System Maintenance Programs

A. I can't figure out how to demonstrate compliance with the requirements for the highest level of monitoring of Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?

Demonstrating compliance with the requirements for the highest level of monitoring any particular component of Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This Standard does not presume to specify what documentation must be developed; only that it must be documented.

There may actually be some equipment available that is capable of meeting these highest levels of monitoring criteria, in which case it may be maintained according to the highest level of monitoring shown on the Tables. However, even if there is no equipment available today that can meet this level of monitoring; the Standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the Standard technology-neutral. The standard drafting team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that are certainly coming to the industry.

B. What forms of evidence are acceptable?

Acceptable forms of evidence, as relevant for the Requirement being documented, include but are not limited to:

- Process documents or plans
- Data (such as relay settings sheets, photos, SCADA, and test records)
- Database lists, records and/or screen shots that demonstrate compliance information
- Prints, diagrams and/or schematics
- Maintenance records
- Logs (operator, substation, and other types of log)
- Inspection forms
- Mail, memos, or email proving the required information was exchanged, coordinated, submitted or received
- Check-off forms (paper or electronic)
- Any record that demonstrates that the maintenance activity was known, accounted for, and/or performed.

C. If I replace a failed Protection System component with another component, what testing do I need to perform on the new component?

The replacement component must be tested to a degree that assures that it will perform as intended. If it is desired to reset the Table 1 maintenance interval for the replacement component, all relevant Table 1 activities for the component should be performed.

D. Please use a specific example to demonstrate the data retention requirements.

The data retention requirements are intended to allow the availability of maintenance records to demonstrate that the time intervals in your maintenance plan were upheld. For example: "Company A" has a maintenance plan that requires its electro-mechanical protective relays be tested, for routine scheduled tests, every 3 calendar years with a maximum allowed grace period of an additional 18 months. This entity would be required to maintain its records of maintenance of its last two routine scheduled tests. Thus its test records would have a latest routine test as well as its previous routine test. The interval between tests is therefore provable to an auditor as being within "Company A's" stated maximum time interval of 4.5 years.

The intent is not to require three test results proving two time intervals, but rather have two test results proving the last interval. The drafting team contends that this minimizes storage requirements while still having minimum data available to demonstrate compliance with time intervals.

Realistically, the Standard is providing advanced notice of audit team documentation requests; this type of information has already been requested by auditors.

If an entity prefers to utilize Performance Based Maintenance then statistical data may well be retained for extended periods to assist with future adjustments in time intervals.

2. Time-Based Protection System Maintenance (TBM) Programs

A. What does this Maintenance Standard say about commissioning? Is it necessary to have documentation in your maintenance history of the completion of commission testing?

This standard does not establish requirements for commission testing. Commission testing includes all testing activities necessary to conclude that a facility has been built in accordance with design. While a thorough commission testing program would include, either directly or indirectly, the verification of all those Protection System attributes addressed by the maintenance activities specified in the Tables of PRC-005-2, verification of the adequacy of initial installation necessitates the performance of testing and inspections that go well beyond these routine maintenance activities. For example, commission testing might set baselines for future tests; perform acceptance tests and/or warranty tests; utilize testing methods that are not generally done routinely like staged-fault-tests.

However, many of the Protection System attributes which are verified during commission testing are not subject to age related or service related degradation and need not be re-verified within an ongoing maintenance program. Example – it is not necessary to re-verify correct terminal strip wiring on an ongoing basis.

PRC-005-2 assumes that thorough commission testing was performed prior to a protection system being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components such that a properly built and commission tested Protection System will continue to function as designed over its service life.

It should be noted that commission testing frequently is performed by a different organization than that which is responsible for the ongoing maintenance of the Protection System. Furthermore, the commission testing activities will not necessarily correlate directly with the maintenance activities required by the standard. As such, it is very likely that commission testing records will deviate significantly from maintenance records in both form and content and therefore, it is not necessary to maintain commission testing records within the maintenance program documentation.

Notwithstanding the differences in records, an entity would be wise to retain commissioning records to show a maintenance start date. (See next FAQ).

B. How do you determine the initial due date for maintenance?

The initial due date for maintenance should be based upon when a facility and its associated Protection System were placed in service. Alternatively, an entity may choose to use the date of completion of the commission testing of the Protection System component as the starting point in determining its first maintenance due dates. Whichever method is chosen, for newly installed Protection Systems the maintenance program should clearly identify when maintenance is first due.

It is conceivable that there can be a (substantial) difference in time between the date of testing as compared to the date placed into service. The use of the “Calendar Year” language can help determine the next due date without too much concern about being non-compliant for missing test dates by a small amount (provided your dates are not already at the end of a year). However, if there is a substantial amount of time difference between testing and in-service dates then the testing date should be followed because it is the degradation of components that is the concern. While accuracy fluctuations may decrease when components are not energized there are cases when degradation can take place even though the device is not energized. Minimizing the time between commissioning tests and in-service dates will help.

C. The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?

No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals. The maintenance intervals were selected with typical plant outages, among other things, in mind.

D. If I am unable to complete the maintenance as required due to a major natural disaster (hurricane, earthquake, etc), how will this affect my compliance with this standard.

The Sanction Guidelines of the North American Electric Reliability Corporation effective January 15, 2008 provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.

E. What if my observed testing results show a high incidence of out-of-tolerance relays, or, even worse, I am experiencing numerous relay misoperations due to the relays being out-of-tolerance?

The established maximum time intervals are mandatory only as a not-to-exceed limitation. The establishment of a maximum is measurable. But, any entity can choose to test some or all of their Protection System components more frequently (or, to express it differently, exceed the minimum requirements of the Standard). Particularly, if you find that the maximum intervals in the Standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently. A high incidence of relay Misoperations is in no one's best interest. The BES and an entity's bottom line both suffer.

F. We believe that the 3-month interval between inspections is unneccessary, why can we not perform these inspections twice per year?

The standard drafting team believes that routine monthly inspections are the norm. To align routine station inspections with other important inspections the 3-month interval was chosen. In lieu of station visits many activities can be accomplished with automated monitoring and alarming.

G. Our maintenance plan calls for us to perform routine protective relay tests every 3 years; if we are unable to achieve this schedule but we are able to complete the procedures in less than the Maximum Time Interval then are we in or out of compliance?

You are out of compliance. You must maintain your equipment to your stated intervals within your maintenance plan. The protective relays (and any Protection System component) cannot be tested at intervals that are longer than the maximum allowable interval stated in the Tables and yet you must conform to your own maintenance plan. Therefore you should design your maintenance plan such that it is not in conflict with the Minimum Activities and the Maximum Intervals. You then must maintain your equipment according to your maintenance plan. You will end up being compliant with both the standard and your own plan.

H. How do I achieve a "grace period" without being out of compliance?

For the purposes of this example, concentrating on just unmonitored protective relays, because there are more relays out there than anything else – Table 1-1 specifies a maximum time interval (between the mandated maintenance activities) of 6 calendar years. Your plan must ensure that your unmonitored relays are tested at least once every 6 calendar years. You could, within your PSMP, require that your unmonitored relays be tested every 4 calendar years with a maximum allowable time extension of 18 calendar months. This allows an entity to have deadlines set for the auto-generation of work orders but still have the flexibility in scheduling complex work schedules. This also allows for that 18 calendar months to act as a buffer, a grace period, in the event of unforeseen events. You will note that this example of a maintenance plan interval has a planned time of 4 years; it also has a built-in time extension allowed within the PSMP and yet does not exceed the maximum time interval allowed by the standard. So while there are no time extensions allowed beyond the standard, an entity can still have substantial flexibility to maintain their Protection System components.

I. If I miss two battery inspections four times out of 100 protection system components on my transmission system, does that count as 2 percent or 8 percent when counting Violation Severity Level (VSL) for R4?

The entity failed to complete its scheduled program on two of its one hundred protection system components which would equate to two percent for application to the VSL Table for Requirement R4.

3. Performance-Based Protection System Maintenance (PBM) Programs

A. I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?

Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for performance-based maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

B. Can an owner go straight to a performance-based maintenance program schedule, if they have previously gathered records?

Yes. An owner can go to a performance-based maintenance program immediately. The owner will need to comply with the requirements of a performance-based maintenance program as listed in the standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they cannot prove that they have collected the data as required for a performance-based maintenance program then they will need to wait until they can prove compliance.

C. When establishing a performance-based maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my performance-based intervals?

No. You must use actual in-service test data for the components in the segment.

D. What types of misoperations or events are not considered countable events in the performance-based Protection System Maintenance (PBM) Program?

Countable events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned.

For this purpose of tracking hardware issues, human errors resulting in Protection System misoperations during system installation or maintenance activities are not considered countable events. Examples of excluded human errors include relay setting errors, design errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System components. Examples of misapplication of Protection System components include wrong CT or PT tap position, protective relay function misapplication, and components not specified correctly for their installation. Obviously, if one is setting up relevant data about hardware failures then human failures should be eliminated from the hardware performance analysis.

One example of human-error is not pertinent data might be in the area of testing “86” Lock-Out Relays (LOR). “Entity A” has two types of LOR’s type “X” and type “Y”; they want to move into a performance based maintenance interval. They have 1000 of each type, so the population variables are met. During electrical trip testing of all of their various schemes over the initial six-year interval they find zero type “X” failures, but human error led to tripping a BES element 100 times; they find 100 type “Y” failures and had an additional 100 human-error caused tripping incidents. In this example the human-error caused misoperations should not be used to judge the performance of either type of LOR. Analysis of the data might lead “Entity A” to change time intervals. Type “X” LOR can be placed into extended time interval testing because of its low failure rate (zero failures) while Type “Y” would have to be tested more often than every 6 calendar years (100 failures divided by 1000 units exceeds the 4% tolerance level).

Certain types of Protection System component errors that cause misoperations are not considered countable events. Examples of excluded component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

E. What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance for mal-performing segments in a performance-based maintenance system. Some examples are listed below.

- The maximum allowable interval, as established by the performance-based maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment.
- Identifiable sub-groups of components within the established segment, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a performance-based maintenance program in order to remain within the program.
- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.
- Components within the mal-performing segment can be replaced with other components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

F. If I find (and correct) a maintenance-correctable issue as a result of a misoperation investigation (Re: PRC-004), how does this affect my performance-based maintenance program?

If you perform maintenance on a Protection System component for any reason (including as part of a PRC-004 required misoperation investigation/corrective action), the actions performed can count as a maintenance activity, and "reset the clock" on everything you've done. In a performance-based maintenance program, you also need to record the maintenance-correctable issue with the relevant component group and use it in the analysis to determine your correct performance-based maintenance interval for that component group. Note that "resetting the clock" should not be construed as interfering with an entity's routine testing schedule because the "clock-reset" would actually make for a decreased time interval by the time the next routine test schedule comes around.

For example a relay scheme, consisting of 4 relays, is tested on 1-1-11 and the PSMP has a time interval of 3 calendar years with an allowable extension of 1 calendar year. The relay would be due again for routine testing before the end of the year 2015. This mythical relay scheme has a misoperation on 6-1-12 that points to one of the four relays as bad. Investigation proves a bad relay and a new one is tested and installed in place of the original. This replacement relay actually could be retested before the end of the year 2016 (clock-reset) and not be out of compliance. This requires tracking maintenance by individual relays and is allowed. However, many companies schedule maintenance in other ways like by substation or by circuit breaker or by relay scheme. By these methods of tracking maintenance that "replaced relay" will be retested before the end of the year 2015. This is also acceptable. In no case was a particular relay tested beyond the PSMP of 4 years max, nor was the 6 year max of the standard exceeded. The entity can reset the clock if they desire or the entity can continue with original schedules and, in effect, test even more frequently.

G. Why are batteries excluded from PBM? What about exclusion of batteries from condition based maintenance?

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a performance-based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the electro-chemical process to completely isolate all of the performance-changing criteria.

Similarly Functional Entities that want to establish a condition-based maintenance program using the highest levels of monitoring; resulting in the least amount of hands-on maintenance activity, of the battery used in a station dc supply cannot completely eliminate some periodic maintenance. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries. However, higher degrees of monitoring of a battery can eliminate the requirement for some periodic testing and some inspections (see Table 1-4).

H. Please provide an example of the calculations involved in extending maintenance time intervals using PBM.

Entity has 1000 GE-HEA lock-out relays; this is greater than the minimum sample requirement of 60

They start out testing all of the relays within the prescribed Table requirements (6 year max) by testing the relays every 5 years. The entity's plan is to test 200 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 6 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 6 failures in the 200 units tested. 6/200= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 10 years.

This represents a rate of 100 units tested per year; entity selects 100 units to be tested in the following year.

After that year of testing these 100 units the entity again finds 6 failed units. 6/100= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 8 years. This means that they will now test 125 units per year (1000/8). The entity has just two years left to get the test rate corrected.

After a year they again find 6 failures out of the 125 units tested. 6/125= 5% failures.

In response to the 5% failure rate, the entity decreases the testing interval to 7 years. This means that they will now test 143 units per year (1000/7). The entity has just one year left to get the test rate corrected.

After a year they again find 6 failures out of the 143 units tested. 6/143= 4.2% failures.

(Note that the entity has tried 5 years and they were under the 4% limit and they tried 7 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 5 years.)

Instead, in response to the 5% failure rate, the entity decreases the testing interval to 6 years. This means that they will now test 167 units per year (1000/6).

After a year they again find 6 failures out of the 167 units tested. 6/167= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 6 years or less. Entity chose 6 year interval and effectively extended their TBM (5 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the “5% of components” requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the “3 years” requirement; this is there to prevent an entity from “gaming the system”. An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	5 yrs	200	6	3%	Yes	10 yrs
2	1000	10 yrs	100	6	6%	Yes	8 yrs
3	1000	8 yrs	125	6	5%	Yes	7 yrs
4	1000	7 yrs	143	6	4.2%	Yes	6 yrs
5	1000	6 yrs	167	6	3.6%	No	6 yrs

V Group by Monitoring Level:

1. All Monitoring Levels

A. Please provide an example of the unmonitored versus other levels of monitoring available?

An unmonitored Protection System has no monitoring and alarm circuits on the Protection System components. A Protection System component that has monitoring attributes but no alarm output connected is considered to be un-monitored.

A monitored Protection System or an individual monitored component of a Protection System has monitoring and alarm circuits on the Protection System components. The alarm circuits must alert, within 24 hours, a location wherein corrective action can be initiated. This location might be, but not limited to an Operations Center, Dispatch Office, Maintenance Center or even a portable SCADA system.

There can be a combination of monitored and unmonitored Protection Systems within any given scheme, substation or plant; there can also be a combination of monitored and unmonitored components within any given Protection System.

Example #1: A combination of monitored and unmonitored components within a given Protection System might be:

◊ A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center. (monitored)
◊ Instrumentation transformers, with no monitoring, connected as inputs to that relay. (unmonitored)
◊ A vented lead-acid battery with low voltage alarm and unintentional grounds detection alarm connected to SCADA. (monitored except for electrolyte level)

◊ A circuit breaker with a trip coil and the trip circuit is not monitored. (unmonitored)

Given the particular components and conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities"), the particular components have maximum activity intervals of:

◊ Every 3 calendar months check electrolyte level (cell voltage and unintentional ground detection is being maintained more frequently by the monitoring system).
◊ Every 18 calendar months check battery bank ohmic values (if performance tests are not opted), battery float voltage and battery rack integrity.
◊ Every 6 calendar years battery performance test (if ohmic tests are not opted), battery charger alarms verified and trip test circuit breakers, electro-mechanical lock-out relays and auxiliary relays.
◊ Every 12 calendar years the microprocessor relay, the instrumentation transformers and the control circuitry are verified.

Example #2: A combination of monitored and unmonitored components within a given Protection System might be:

◊ A microprocessor relay with integral alarm that is not connected to SCADA. (unmonitored)
◊ Instrument transformers, with no monitoring, connected as inputs to that relay. (monitored)
◊ A vented lead-acid battery with low voltage and ground-detection alarms connected to SCADA. (monitored except for electrolyte level)
◊ A circuit breaker with a trip coil, with no circuits monitored. (unmonitored)

Given the particular components and conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities"), the particular components have maximum activity intervals of:

◊ Every 3 calendar months check electrolyte level (cell voltage and unintentional ground detection is being maintained more frequently by the monitoring system).
◊ Every 18 calendar months check battery bank ohmic values (if performance tests are not opted), battery float voltage and battery rack integrity.
◊ Every 6 calendar years microprocessor relay is verified, battery performance test (if ohmic tests are not opted), battery charger alarms verified and trip test circuit breakers, electro-mechanical lock-out relays and auxiliary relays.
◊ Every 12 calendar years the instrumentation transformers and the control circuitry are verified.

Example #3: A combination of monitored and unmonitored components within a given Protection System might be:

◊ A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center. (monitored)
◊ Instrument transformers, with no monitoring, connected as inputs to that relay (unmonitored)
◊ Battery without any alarms connected to SCADA (unmonitored)
◊ Circuit breaker with a trip coil, with no circuits monitored (unmonitored)

Given the particular components, conditions, and using the Table 1 (“Maximum Allowable Testing Intervals and Maintenance Activities”), the particular components shall have maximum activity intervals of:

- ◊ Every 3 calendar months check battery bank voltage, check for unintentional grounds and check electrolyte level.
- ◊ Every 18 calendar months check battery bank ohmic values (if performance tests are not opted), battery float voltage and battery rack integrity.
- ◊ Every 6 calendar years battery performance test (if ohmic tests are not opted), battery charger alarms verified and trip test circuit breakers, electro-mechanical lock-out relays and auxiliary relays.
- ◊ Every 12 calendar years the microprocessor relay, the instrumentation transformers and the control circuitry are verified.

B. What is the intent behind the different levels of monitoring?

The intent behind different levels of monitoring is to allow less frequent manual intervention when more information is known about the condition of Protection System components. Condition-Based Maintenance is a valuable asset to improve reliability.

C. Do all monitoring levels apply to all components in a protection system?

No. For some components in a protection system, certain levels of monitoring will not be relevant. For example a battery will always need some kind of inspection.

D. My microprocessor relays and dc circuit alarms are contained on relay panels in a 24-hour attended control room. Does this qualify as an extended time interval condition-based system?

Yes, provided the station attendant (plant operator, etc.) monitors the alarms and other indications (comparable to the monitoring attributes) and reports them within the given time limits that are stated in the criteria of the Tables.

E. When documenting the basis for inclusion of components into the appropriate levels of monitoring as per Requirement R2 of the standard, is it necessary to provide this documentation about the device by listing of every component and the specific monitoring attributes of each device?

No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a component type or portion thereof.
For example, it would be permissible to document the conclusion that all BES substation dc supply battery chargers are Monitored by stating the following within the program description:

> “All substation dc supply battery chargers are considered Monitored and subject to the rows for monitored equipment of Table 1-4 requirements as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center.”

Similarly, it would be acceptable to use a combination of a global statement and a device level list of exclusions. Example:

> “Except as noted below, all substation dc supply battery chargers are considered Monitored and subject to the rows for monitored equipment of Table 1-4 requirements as all substation dc supply battery chargers are equipped with dc voltage alarms and

ground detection alarms that are sent to the manned control center. The dc supply battery chargers of Substation X, Substation Y, and Substation Z are considered Unmonitored and subject to the rows for unmonitored equipment in Table 1-4 requirements as they are not equipped with ground detection capability."

Regardless whether this documentation is provided by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure but should be retrievable if requested by an auditor.

2. Unmonitored Protection Systems

A. We have an electromechanical (unmonitored) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer's high-side and low-side circuit breakers. What testing must be done for this system?

This system is made up of components that are all unmonitored. Assuming a time-based protection system maintenance program schedule (as opposed to a performance-based maintenance program), each component must be maintained per the most frequent hands-on activities listed in the Tables 1-1 through 1-5.

3. Monitored Protection Systems

A. We have a 30 year old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Is this an unmonitored or a partially-monitored system? How often must I perform maintenance?

The protective relay is monitored and can be maintained every 12 years or when a maintenance correctable issue arises. The control circuitry has no electro-mechanical parts and can be maintained every 12 years. The trip coil(s) has to be electrically operated at least once every 6 years.

B. How do I verify the A/D converters of microprocessor-based relays?

There are a variety of ways to do this. Two examples would be: using values gathered via data communications and automatically comparing these values with values from other sources, or using groupings of other measurements (such as vector summation of bus feeder currents) for comparison. Many other methods are possible.

C. How is the performance criteria of Protection System communications equipment involved in the maintenance program?

An entity determines the acceptable performance criteria depending on the technology implemented. If the communications channel performance of a Protection System varies from the pre-determined performance criteria for that system then these results should be investigated and resolved.

D. My system has alarms that are gathered once daily through an auto-polling system; this is not really a conventional SCADA system but does it meet the Table 1 requirements for inclusion as a monitored system?

Yes, provided the auto-polling that gathers the alarms reports those alarms to a location where the action can be initiated to correct the maintenance-correctable issue. This location does not have to be the location of the engineer or the technician that will eventually repair the problem, but rather a location where the action can be initiated.

4. Monitored Protection Systems that also monitor alarm path failures

A. Why are there activities defined for levels of monitoring a Protection System component when that level of technology may not yet be available?

There may already be some equipment available that is capable of meeting the highest levels of monitoring criteria listed in the Tables. However, even if there is no equipment available today that can meet this level of monitoring the Standard establishes the necessary requirements for when such equipment becomes available. By creating a roadmap for development, this provision makes the Standard technology-neutral. The standard drafting team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that may be coming to the industry.

NERC Protection System Maintenance Standard PRC-005-2

FREQUENTLY ASKED QUESTIONS - Practical Compliance and Implementation

~~April 16~~November 17, 2010

Informative Annex to Standard PRC-005-2

Prepared by the

Protection System Maintenance and Testing Standard Drafting Team

Table of Contents

Introduction

The following is a draft collection of questions and answers that the PSMT SDT believes could be helpful to those implementing NERC Standard PRC-005-2 Protection System Maintenance. As the draft standard proceeds through development, this FAQ document will be revised, including responses to key or frequent comments from the posting process. The FAQ will be organized at a later time during the development of the draft Standard.

This FAQ document will support both the Standard and the associated Technical Reference document.

Executive Summary

- Write later if needed

Terms Used in PRC-005-2

~~**Maintenance Correctable Issue** – As indicated in footnote 2 of the draft standard, a maintenance correctable issue is a failure of a device to operate within design parameters that can not be restored to functional order by repair or calibration while performing the initial on-site maintenance activity, and that requires follow-up corrective action.~~

~~**Segment** – As indicated in *PRC-005-2 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*, a segment is a "A grouping of Protection Systems or components of a particular model or type from a single manufacturer, with other common factors such that consistent performance is expected across the entire population of the segment, and shall only be defined for a population of 60 or more individual components."~~

~~**Component** – This equipment is first mentioned in Requirement 1.1 of this standard. A component is any individual discrete piece of equipment included in a Protection System, such as a protective relay or current sensing device. Types of components are listed in Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection Systems"). For components such as dc circuits, the designation of what constitutes a dc control circuit component is somewhat arbitrary and is very dependent upon how an entity performs and tracks the testing of the dc circuitry. Some entities test their dc circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of "dc control circuit components." Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.~~

~~**Countable Event** – As indicated in footnote 4 of *PRC-005-2 Attachment A, Criteria for a Performance-based Protection System Maintenance Program*, countable events include any failure of a component requiring repair or replacement, any condition discovered during the verification activities in Table 1a through Table 1c which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are *not* included in Countable Events.~~

Frequently Asked Questions

I General FAQs:

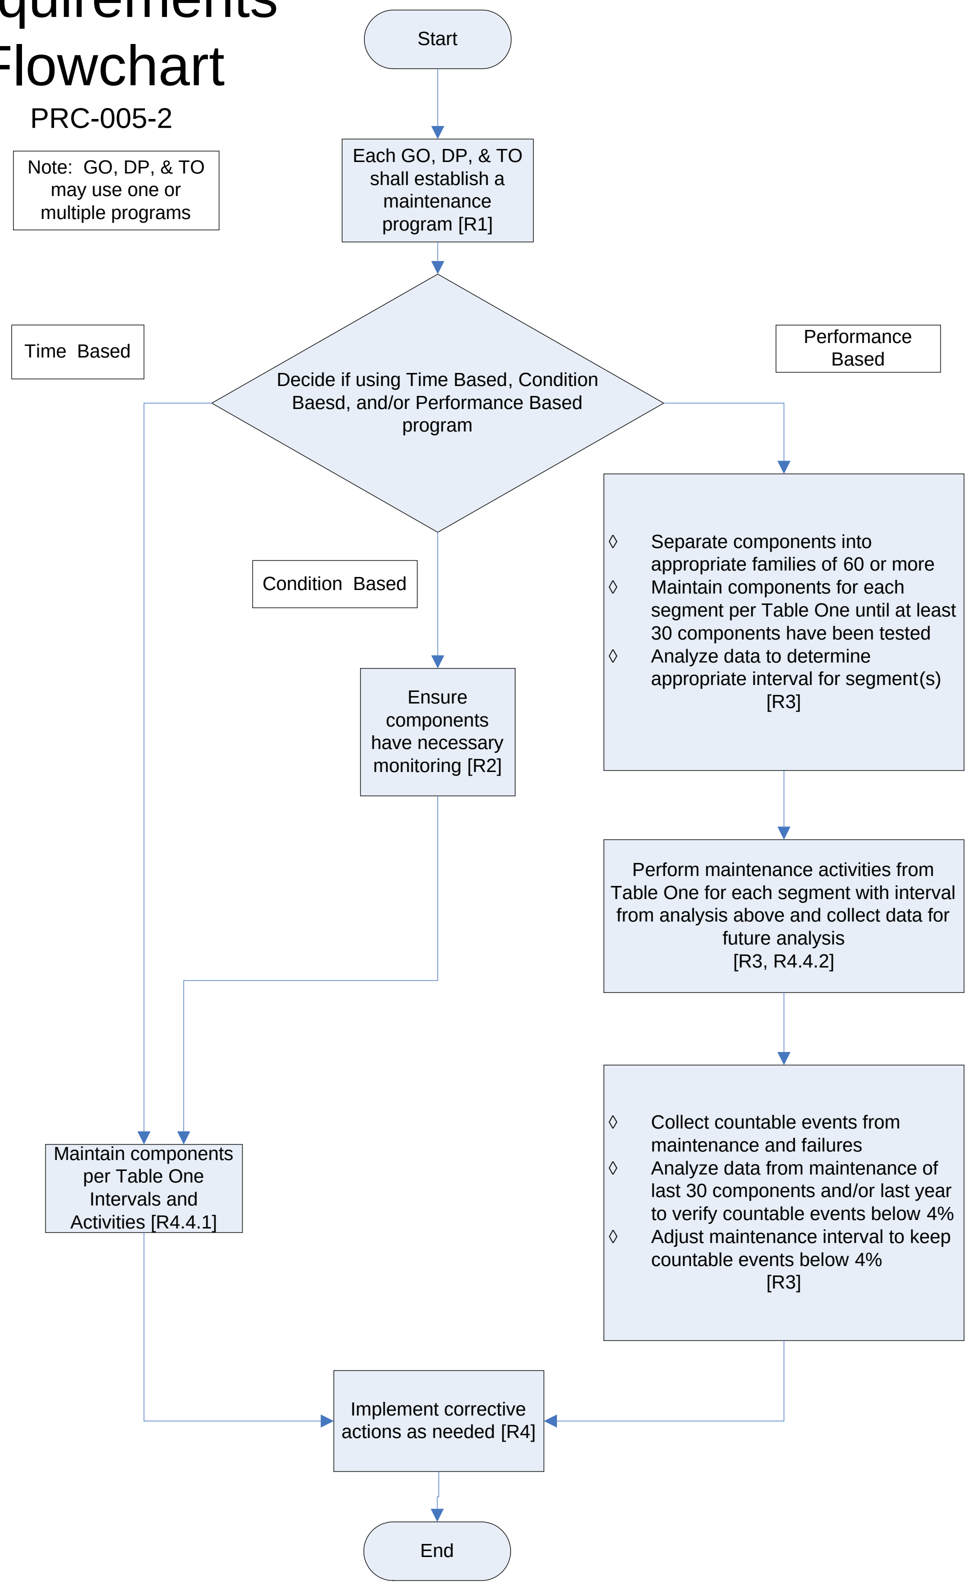
1. The standard seems very complicated, and is difficult to understand. Can it be simplified?

Because the standard is establishing parameters for condition-based Maintenance (R2) and performance-based Maintenance (R3) in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to ~~follow R1 and R4~~ and perform ONLY time-based maintenance according to ~~Table 1a, eliminating R2 and R3 from consideration altogether.~~the unmonitored rows of the Tables. If an entity then wishes to take advantage of monitoring on its Protection System components~~, R2 comes into play, along with Tables 1b and 1c~~ and its available lengthened time intervals then it may, as long as the component has the listed monitoring attributes. If an entity wishes to use historical performance of its Protection System components to perform performance-based Maintenance, then R3 applies.

Please see the following diagram, which provides a “flow chart” of the standard.

Requirements Flowchart

PRC-005-2



II Group by Type of Protection System Component:

1. All Protection System Components

A. Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this standard?

No. As stated in Requirement R1, this standard covers protective relays that use measurements of voltage, current and/or phase angle to determine anomalies and to trip a portion of the BES. Reclosers, reclosing relays, closing circuits and auto-restoration schemes are used to cause devices to close as opposed to electrical-measurement relays and their associated circuits that cause circuit interruption from the BES; such closing devices and schemes are more appropriately covered under other NERC Standards. There is one notable exception: if a Special Protection System incorporates automatic closing of breakers, the related closing devices are part of the SPS and must be tested accordingly.

B. Why does PRC-005-2 not specifically require maintenance and testing procedures as reflected in the previous standard, PRC-005-1?

PRC-005-1 does not require detailed maintenance and testing procedures, but instead requires summaries of such procedures, and is not clear on what is actually required. PRC-005-2 requires a documented ~~Maintenance~~maintenance program, and is focused on establishing ~~Requirements~~requirements rather than prescribing methodology to meet those ~~Requirements~~requirements. Between the activities identified in the tables 1-1 through 1-5 and Table 2 (collectively the "Tables ~~1a, 1b, and 1c,~~"), and the various components of the definition established for a "Protection System Maintenance Program", PRC-005-2 establishes the activities and time-basis for a Protection System Maintenance Program to a level of detail not previously required.

2. Protective Relays

A. How do I approach testing when I have to upgrade firmware of a microprocessor relay?

~~The component "Upkeep" in the definition of a Protection System Maintenance Program, addresses "Routine activities necessary to assure that the component remains in good working order and implementation of any manufacturer's hardware and software service advisories which are relevant to the application of the device." The Maintenance Activities specified in Table 1a, Table 1b, and Table 1c do not present any requirements related to Upkeep for Protective Relays. However, the entity should assure that the relay continues to function properly after implementation of firmware changes.~~

The entity should ensure that the relay continues to function properly after implementation of firmware changes. Some entities may have a R&D department that might routinely run acceptance tests on devices with firmware upgrades before allowing the upgrade to be installed. Other entities may rely upon the vigorous testing of the firmware OEM. An entity has the latitude to install devices and/or programming that they believe will perform to their satisfaction. If an entity should choose to perform the maintenance activities specified in the Tables following a firmware upgrade then they may, if they choose, reset the time clock on that set of maintenance activities so that they would not have to repeat the maintenance on its regularly scheduled cycle. (However, for simplicity in maintenance schedules, some entities may choose to not reset this time clock; it is merely a suggested option.)

B. Please clarify what is meant by restoration in the definition of maintenance.

The ~~component~~description of "Restoration" in the definition of a Protection System Maintenance Program, addresses corrective activities necessary to assure that the component is returned to working order following the discovery of its failure or malfunction. The Maintenance Activities specified in ~~Table 1a, Table 1b, and Table 1c~~the Tables do not present any requirements related to Restoration; R4.3 of the standard does require that the entity "initiate any necessary activities to correct unresolved maintenance correctable issues". Some examples of restoration (or correction of maintenance-correctable issues) include, but are not limited to, replacement of capacitors in distance relays to bring them to working order; replacement of relays, or other Protection System components, to bring the Protection System to working order; upgrade of electro-mechanical or solid-state protective relays to micro-processor based relays following the discovery of failed components. Restoration, as used in this context is not to be confused with Restoration rules as used in system operations. Maintenance activity necessarily includes both the detection of problems and the repairs needed to eliminate those problems. This standard does not identify all of the Protection System problems that must be detected and eliminated, rather it is the intent of this standard that an entity determines the necessary working order for their various devices and keeps them in working order. If an equipment item is repaired or replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work

C. If I upgrade my old relays then do I have to maintain my previous equipment maintenance documentation?

If an equipment item is repaired or replaced then the entity can restart the maintenance-activity-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements. The requirements in the standard are intended to ensure that an entity has a maintenance plan and that the entity adheres to minimum activities and maximum time intervals. The documentation requirements are intended to help an entity demonstrate compliance. For example, saving the dates and records of the last two maintenance ~~cycles~~activities is intended to demonstrate compliance with the interval. Therefore, if you upgrade or replace equipment then you still must maintain the documentation for the previous equipment, thus demonstrating compliance with the time interval requirement prior to the replacement action.

D. What is meant by "Verify that settings are as specified" maintenance activity in ~~tables 1a and 1b~~Table 1-1?

Verification of settings is an activity directed mostly towards microprocessor based relays.

For relay maintenance departments that choose to test microprocessor based relays in the same manner as electro-mechanical relays are tested, the testing process sometimes requires that some specific functions be disabled. Later tests might enable the functions previously disabled but perhaps still other functions or logic statements were then masked out. It is imperative that, when the relay is placed into service, the settings in the relay be the settings that were intended to be in that relay or as the Standard states "…settings are as specified."

Many of the microprocessor based relays available today have software tools which provide this functionality and generate reports for this purpose.

For evidence or documentation of this requirement a simple recorded acknowledgement that ~~this was done~~the settings were checked to be as specified is sufficient.

The drafting team was careful not to require "…that the relay settings be correct…" because it was believed that this might then place a burden of proof that the specified settings would result in the correct intended operation of the interrupting device. While that is a noble intention, the measurable proof of such a requirement is immense. The intent is simply to check that the settings in the relay match the settings specified to those placed into the relay.

E. Are electromechanical relays included in the "Verify that settings are as specified" maintenance activity in ~~tables 1a and 1b~~Table 1-1?

Verification of settings is an activity directed towards the application of protection related functions of microprocessor based relays. Electromechanical relays require calibration verification by voltage and/or current injection, and thus the settings are verified during calibration activity. In the example of a time-overcurrent relay, a minor deviation in time dial, versus the settings, may be acceptable as long as the relay calibration is within accepted tolerances at the injected current amplitudes. A major deviation may require further investigation, as it could indicate a problem with the relay or an incorrect relay style for the application.

F. I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?

This standard addresses only devices "that are applied on, or are designed to provide protection for the BES." Protective relays, providing only the functions mentioned in the question, are not included.

G. I use my protective relays for fault and disturbance recording, collecting oscillographic records and event records via communications for fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?

For relays used only as disturbance monitoring equipment, the NERC standard PRC-018-1 R3 & R6 states the maintenance requirements, and is being addressed by a Standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays "that are applied on, or are designed to provide protection for the BES," this standard applies, even if they also perform DME functions.

H. We have a number of installations where we have changed our Protection System components. Some of the changes were upgrades, but others were simply system rating changes that merely required taking relays "out-of-service". What are our responsibilities when it comes to "out-of-service" devices?

Assuming that your system ~~uprates~~up-rates, upgrades and overall changes meet any and all other requirements and standards then the requirements of PRC-005-2 are simple – if the Protection system component performs a Protection system function then it must be maintained. If the component no longer performs Protection System functions than it does not require maintenance activities under the Tables of PRC-005-2. While many entities might physically remove a component that is no longer needed there is no requirement in PRC-005-2 to remove such component(s). Obviously, prudence would dictate that an "out-of-service" device is truly made inactive. There are no record requirements listed in PRC-005-2 for Protection System components not used.

I. While performing relay testing of a protective device on our Bulk Electric System it was discovered that the protective device being tested was either broken or out of calibration. Does this satisfy the relay testing requirement even though the protective device tested bad, and may be unable to be placed back into service?

Yes, PRC-005-2 requires entities to perform relay testing on protective devices on a given maintenance cycle interval. By performing this testing, the entity has satisfied PRC-005-2 requirement although the protective device may be unable to be returned to service under normal calibration adjustments. R4.3 states (the entity must):
The entity must assure either that the components are within acceptable parameters at the conclusion of the maintenance activities or initiate any necessary activities to correct unresolved maintenance correctable issues.

J. If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R4.3) (in essence) state that the entity assure the components are within the owner's acceptable operating parameters, if not then actions must be initiated to correct the deviance. The type of corrective activity is not stated; however it could include repairs or replacements. Documentation is always a necessity ("*If it is not documented then it wasn't done!*")
Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

K. What calibration tolerance should be applied on electromechanical relays?

Each entity establishes their own acceptable tolerances when applying protective relaying on their system. For some Protection System components, adjustment is required to bring measurement accuracy within the parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

L. What is meant by "verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System?"

Any input or output that "affects the tripping" of the breaker is included in the scope of I/O to be verified. By "affects the tripping" one needs to realize that sometimes there are more Inputs and Outputs than simply the output to the trip coil. Many important protective functions include things like Breaker Fail Initiation, Zone Timer Initiation and sometimes even 52a/b contact inputs are needed for a protective relay to correctly operate.

Each input should be "picked up" or "turned on and off" and verified as changing state by the microprocessor of the relay. Each output should be "operated" or "closed and opened" from the microprocessor of the relay and the output should be verified to change state on the output terminals of the relay.

Each input detector on a component that is needed for a protective function and each output action from a component that is needed for a protective function needs to be tested.

In short, if an entity designed a scheme into the protective functions then that scheme needs to be tested.

3. Voltage and Current Sensing Device Inputs to Protective Relays

A. What is meant by "…verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" Do we need to perform ratio, polarity and saturation tests every few years?

No. You must verify that the protective relay is receiving the expected values from the voltage and current sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. While some examples follow, these are not intended to represent an all-inclusive list; technology advances and ingenuity should not be excluded from making comparisons and verifications:

- Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.
- Compare the individual phase secondary values at the relay panel (with additional testing on the panel wiring to ensure that the values arrive at those relays) with the other phases, and verify that residual currents are within expected bounds
- Observe all three phase currents and the residual current at the relay panel with an oscilloscope, observing comparable magnitudes and proper phase relationship, with additional testing on the panel wiring to ensure that the values arrive at the relays.
- Compare the values, as determined by the questioned relay (such as, but not limited to, a query to the microprocessor relay), to another protective relay monitoring the same line, with currents supplied by different CT's.
- Compare the secondary values, at the relay with values measured by test instruments (such as, but not limited to multi-meters, voltmeter, clamp-on ammeters, etc) and verified by calculations and known ratios to be the values expected. For example a single PT on a 100KV bus will have a specific secondary value that when multiplied by the PT ratio arrives at the expected bus value of 100KV.
- Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.
- Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

The point of the verification procedure is to ensure that all of the individual components are functioning properly; and that, an ongoing proactive procedure is in place to re-check the various components of the protective relay measuring systems.

B. The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?

Since these inputs are verified at commissioning, maintenance verification requires ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0.

These quantities also may be ~~also~~ verified by use of oscillographic records for connected microprocessor relays as recorded during system disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known fault locations.

C. Is wiring insulation or hi-pot testing required by this Maintenance Standard?

No, wiring insulation and equipment hi-pot testing are not specifically required by the Maintenance Standard. However, if the method of verifying CT and PT inputs to the relay involves some other method than actual observation of current and voltage transformer secondary inputs to the relay, it might be necessary to perform some sort of cable integrity test to verify that the instrument transformer secondary signals are actually making it to the relay and not being shunted off to ground. For instance, you could use CT excitation tests and PT turns ratio tests and compare to baseline values to verify that the instrument transformer outputs are acceptable. However, to conclude that these acceptable transformer instrument output signals are actually making it to the relay inputs, it also would be necessary to verify the insulation of the wiring between the instrument transformer and the relay.

D. My plant generator and transformer relays are electromechanical and do not have metering functions as do microprocessor based relays. In order for me to compare the instrument transformer inputs to these relays to the secondary values of other metered instrument transformers monitoring the same primary voltage and current signals, it would be necessary to temporarily connect test equipment like voltmeters and clamp on ammeters to measure the input signals to the relays. This practice seems very risky and a plant trip could result if the technician were to make an error while measuring these current and voltage signals. How can I avoid this risk? Also, what if no other instrument transformers are available which monitor the same primary voltage or current signal?

Comparing the input signals to the relays to the outputs of other independent instrument transformers monitoring the same primary current or voltage is just one method of verifying the instrument transformer inputs to the relays but is not required by the standard. Plants can choose how to best manage their risk. If online testing is deemed too risky, offline tests such as, but not limited to, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately "verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" while eliminating the risk of tripping an in service generator or transformer. Similarly, this same offline test methodology can be used to verify the relay input voltage and current signals to relays when there are no other instrument transformers monitoring available for purposes of signal comparison.

4. Protection System Control Circuitry

A. Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?

Yes, provided the entire Protective System is tested within the individual components' maximum allowable testing intervals.

B. The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?

Requirements in PRC-005-2 are intended to verify the integrity of tripping circuits, including the breaker trip coil, as well as the presence of auxiliary supply (usually a ~~dc~~ battery) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-2 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

C. How do I test each dc Control Circuit path, as established ~~for level 2 (partially monitored protection systems) monitoring of a~~in Table 1-5 "Protection System Control Circuitry (Trip coils and auxiliary relays)"?

Table ~~1b~~1-5 specifies that each breaker trip coil, auxiliary relay, and lockout relay must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as fault clearing.

D. What does this standard require for testing an Auxiliary Tripping Relay?

Table 1 requires that the trip test must verify that the auxiliary tripping relay(s) and/or lockout relay(s) operate(s) electrically and that their trip output(s) perform as expected. Auxiliary outputs not in a trip path (i.e. ~~alarming~~annunciation or DME input) are not required, by this standard, to be checked.

E. What does a functional (or operational) trip test include?

An operational trip test must be performed on ~~each portion of~~ a trip ~~circuit~~device. Each control circuit path that produces a trip signal must be verified; this includes trip coils, auxiliary tripping relays, lockout relays, and communications-assisted-trip schemes.

A trip test may be an overall test that verifies the operation of the entire trip scheme at once, or it may be several tests of the various portions that make up the entire trip path, provided that testing of the various portions of the trip scheme verifies all of the portions, including parallel paths, and overlaps those portions.

A circuit breaker or other interrupting device needs to be trip tested at least once per trip coil~~..~~.

Discrete-component auxiliary relays and lock-out relays must be verified by trip test. The trip test must verify that the auxiliary or lock-out relay operates electrically and that the relay's trip output(s) change(s) state. Software latches or control algorithms, including trip logic processing implemented as programming component such as a microprocessor relay that take the place of (conventional) discrete component auxiliary relays or lock-out relays do not have to be routinely trip tested.

Normally-closed auxiliary contacts from other devices (for example, switchyard-voltage-level disconnect switches, interlock switches, or pressure switches) which are in the breaker trip path do not need to be tested.

F. Is a Sudden Pressure Relay an Auxiliary Tripping Relay?

No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63, and is excluded from the Standard ~~by footnote 1~~because it does not utilize voltage and/or current measurements to determine anomalies. Devices that use anything other than electrical detection means are excluded.

G. The standard specifically mentions Auxiliary and Lock-out relays; what is an Auxiliary Tripping Relay?

An auxiliary relay, IEEE Device Number 94, is described in IEEE Standard C37.2-2008 as "A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed."

H. What is a Lock-out Relay?

A lock-out relay, IEEE Device Number 86, is described in IEEE Standard C37.2 as "A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely."

I. My mechanical device does not operate electrically and does not have calibration settings; what maintenance activities apply?

You must conduct a test(s) to verify the integrity of the trip circuit. This standard does not cover circuit breaker maintenance or transformer maintenance. The standard also does not cover testing of devices such as sudden pressure relays (63), temperature relays (49), and other relays which respond to mechanical parameters rather than electrical parameters.

5. Station dc Supply

A. What constitutes the station dc supply as mentioned in the definition of Protective System?

The station direct current (dc) supply normally consists of two components: the battery charger and the station battery itself. There are also emerging technologies that provide a source of dc supply that does not include either a battery or charger.

Battery Charger - The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

Station Battery - Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1.

Emerging Technologies - Station dc supplies are currently being developed that use other energy storage technologies beside the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new the maintenance activities for these station dc supplies may change over time.

B. In the Maintenance Activities for station dc supply in Table 1, what do you mean by "continuity"?

Because the Standard pertains to maintenance not only of the station battery, but also the whole station dc supply, continuity checks of the station dc supply are required. "Continuity" as used in Table 1 refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal, otherwise there is no way of determining that a station battery is available to supply dc current to the station.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path the battery set will not be available for service.

C. Why is it necessary to verify the continuity of the dc supply?

In the event of the loss of the ac source or battery charger, the battery must be capable of supplying dc current, both for continuous dc loads and for tripping breakers and switches. Without continuity, the battery cannot perform this function.

If the battery charger is not sized to handle the maximum dc current required to operate the protective systems, it is sized only to handle the constant dc load of the station and the charging current required to bring the battery back to full charge following a discharge. At those stations, the battery charger would not be able to trip breakers and switches if the battery experiences loss of continuity.

At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

◊ Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.

◊ Loss of electrical continuity of the station battery will cause, regardless of the battery charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional 1 to 2 second delay to switch from a low substation dc load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed which could violate system performance standards.

D. How do you verify continuity of the dc supply?

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery unless the battery charger is taken out of service. At that time a break in the continuity of the station battery current path will be revealed because there will be no voltage on the ~~substation~~station dc circuitry.

Although the Standard prescribes what must be done during the maintenance activity it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery. These are not the only possible methods, simply a sampling of some methods:

◊ One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.

◊ A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the various dc-supplied equipment in the station should be considered before using this approach.

◊ Manufacturers of microprocessor ~~based~~controlled battery chargers have developed methods for their equipment to periodically (or continuously) test for battery continuity. For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc load can be measured to confirm continuity.

◊ Applying test current (as in an ohmic testing device) will provide a current that when measured elsewhere in the string, will prove that the circuit is continuous.

No matter how the electrical continuity of a battery set is verified it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1 to insure that the station dc supply ~~will~~has a path that can provide the required current to the Protection System at all times.

E. When should I check the station batteries to see if they have sufficient energy to perform as designed?

The answer to this question depends on the type of battery (valve regulated lead-acid, vented lead acid, or nickel-cadmium), the maintenance activity chosen, and the type of time based monitoring level selected.

For example, if you have a Valve Regulated Lead-Acid (VRLA) station battery, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than every three months. While this interval might seem to be quite short, keep in mind that the 3 month interval is consistent with IEEE guidelines for VRLA batteries; this interval provides an accumulation of data that better shows when a VRLA battery is no longer capable of its design capacity.

If, for a VRLA station battery, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every 3 calendar years.

F. Why in Table 1 are there two Maintenance Activities with different Maximum Maintenance Intervals listed to verify that the station battery can perform as designed?

The two acceptable methods for proving that a station battery can perform as designed are based on two different philosophies. The first activity requires a capacity discharge test of the entire battery set to verify that degradation of one or several components (cells) in the set has not deteriorated to a point where the total capacity of the battery system falls below its designed rating. The second maintenance activity requires tests and evaluation of the internal ohmic measurements on each of the individual cells/units of the battery set to determine that each component can perform as designed and therefore the entire battery set can be verified to perform as designed.

The maximum maintenance interval for discharge capacity testing is longer than the interval for testing and evaluation of internal ohmic cell measurements. An individual component of a battery set may degrade to an unacceptable level without causing the total battery set to fall below its designed rating under capacity testing. However, since the philosophy behind internal ohmic measurement evaluation is based on the fact that each battery component must be verified to be able to perform as designed, the interval for verification by this maintenance activity must be shorter to catch individual cell/unit degradation. It should be noted that even if a battery unit is composed of multiple cells the ohmic test can still be accomplished. The data produced becomes trending data on the multi-cell unit instead of trending individual cells.

G. What is the justification for having two different Maintenance Activities listed in Table 1 to verify that the station battery can perform as designed?

IEEE Standards 450, 1188, and 1106 for vented lead-acid, valve-regulated lead-acid (VRLA), and nickel-cadmium batteries, respectively (which together are the most commonly used substation batteries on the BES) go into great detail about capacity testing of the entire battery set to determine that a battery can perform as designed.

The first maintenance activity listed in Table 1 for verifying that a station battery can perform as designed uses maximum maintenance intervals for capacity testing that were designed to align with the IEEE battery standards. This maintenance activity is applicable for vented lead-acid, valve-regulated lead-acid, and nickel-cadmium batteries.

The second maintenance activity listed in Table 1 for verifying that a station battery can perform as designed uses maximum maintenance intervals for evaluating internal ohmic measurements in relation to their baseline measurements that are based on industry experience, EPRI technical reports and application guides, and the IEEE battery standards. By evaluating the internal ohmic measurements for each cell and comparing that measurement to the cell's baseline ohmic measurement (taken at the time of the battery set's acceptance capacity test), low-capacity cells can be identified and eliminated to keep the battery set capable of performing as designed. This maintenance activity is applicable only for vented lead-acid and VRLA batteries~~.~~; this trending activity has not shown to be effective for NiCd batteries thus the only choices for NiCd batteries are the performance tests (see applicable IEEE guideline for specifics on performance tests). It should be noted that even if a battery unit is composed of multiple cells the ohmic test can still be accomplished. The data produced becomes trending data on the multi-cell unit instead of trending individual cells.

H. Why in Table 1 of PRC-005-2 is there a maintenance activity to inspect the structural intergrity of the battery rack?

The three IEEE standards (1188, 450, and 1106) for VRLA, vented lead-acid, and nickel-cadmium batteries all recommend that as part of any battery inspection the battery rack should be inspected. The purpose of this inspection is to verify that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity. Because the battery rack is specifically designed for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

I. What is required to comply with the "Unintentional Grounds" requirement?

In most cases, the first ground that appears on a battery ~~pole~~ is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many systems are designed to operate favorably under some unintentional DC ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on detected unintentional DC grounds. The standard merely requires that a check be made for the existence of Unintentional DC Grounds. Obviously a "check-off" of some sort will have to be devised by the inspecting entity to ~~demonstrate~~document that a check is routinely done for Unintentional DC Grounds.

J. Where the standard refers to "all cells" is it sufficient to have a documentation method that refers to "all cells" or do we need to have separate documentation for every cell? For example to I need 60 individual documented check-offs for good electrolyte level or would a single check-off per bank be sufficient~~??~~?

A single check-off per battery bank is sufficient~~. –~~ for documentation, as long as the single check-off attests to checking all cells/units.

K. Does this standard refer to Station batteries or all batteries, for example ~~Communication~~Communications Site Batteries?

This standard refers to Station Batteries. The drafting team does not believe that the scope of this standard refers to ~~communication~~communications sites. The batteries covered under PRC-005-2 are the batteries that supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System. The SDT believes that a loss of power to the communications systems at a remote site would cause the communications systems associated with protective relays to alarm at the substation. At this point the corrective actions can be initiated.

L. My VRLA batteries have multiple-cells within an individual battery jar (or unit); how am I expected to comply with the cell-to-cell ohmic measurement requirements on these units that I cannot get to?

The values that are measured at all available terminals will produce results that can be tracked. Thus the trended results become the results of a unit instead of an individual cell. Bad units (regardless of the number of cells per unit) will result in the eventual repair or replacement of multiple cells even if only a single cell actually went bad. Cell-to-cell tests can equate to unit-to-unit tests or jar-to-jar tests. If there is such a thing as a single unit that contains the entire battery for the facility but only brings out the positive and negative posts (as in a car battery) then the testing across these only two available posts will produce usable trending test data.

6. Protection System Communications Equipment

A. What are some examples of mechanisms to check communications equipment functioning?

~~For Level 1~~For unmonitored Protection Systems, various types of communications systems will have different facilities for on-site integrity checking to be performed at least every three months during a substation visit. Some examples are~~: ~~, but not limited to:

- On-off power-line carrier systems can be checked by performing a manual carrier keying test between the line terminals, or carrier ~~checkback~~check-back test from one terminal.
- Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing for a loss-of-guard indication or alarm. For frequency-shift ~~power line~~ power-line carrier systems, the guard signal level meter can also be checked.
- Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
- Digital communications systems typically have ~~some sort of~~a data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

~~For Level 2 partially~~For monitored Protection Systems, various types of communications systems will have different facilities for monitoring the presence of the communications channel, and activating alarms that can be monitored remotely. Some examples are, but not limited to:

- On-off power-line carrier systems can be shown to be operational by automated periodic power-line carrier ~~checkback~~check-back tests, with remote alarming of failures.
- Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
- Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
- Digital communications systems can activate remotely monitored alarms for data reception loss or data error indications.
- ~~For Level 3 fully monitored~~Systems can be queried for the data error rates.

For the highest degree of monitoring of Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays.

- ◊ In many communications systems signal quality measurements including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.
- ◊ Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

B. What is needed for the 3-month inspection of ~~communication~~communications-assisted trip scheme equipment?

The 3-month inspection applies to ~~Level 1 (Unmonitored)~~unmonitored equipment. An example of compliance with this requirement might be, but is not limited to:

With each site visit, check that the equipment is free from alarms, check any metered signal levels, and that power is still applied. While this might be explicit for a particular type of equipment (~~ie~~i.e., FSK equipment), the concept should be that the entity verify that the communications equipment that is used in a Protection System is operable through a cursory inspection and site visit. This site visit can be eliminated on this particular example if the FSK equipment had a monitored alarm on Loss of Guard.

C. Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a ~~communication~~communications system?

This equipment is presently classified as being part of the Protection System Control Circuitry and tested per the portions of Table 1 applicable to Protection System Control Circuitry rather than those portions of the table applicable to ~~communication~~communications equipment.

D. In Table ~~1b~~1-2, the Maintenance Activities section of the Protective System Communications Equipment and Channels refers to the quality of the channel meeting "performance criteria". What is meant by performance criteria?

Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally an alarm will be indicated. For ~~Level 1~~unmonitored systems this alarm will probably be on the panel. For ~~Level 2 and Level 3~~monitored systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each protective system communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm. Following are some examples of protective system communications channel performance ~~criteria~~measuring:

- ◊ For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm.
- ◊ An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use ~~checkback~~check-back testing to determine channel performance. A predetermined signal sequence is sent to the remote end and the remote end decodes this signal and sends a signal sequence back. If the sending end receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.
- ◊ Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.
- ◊ Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase information over the communications path to determine if the fault is located in the protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These limits are determined and set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This standard does not state what the performance criteria will be - it just requires that the entity establish nominal criteria so protective system channel monitoring can be performed.

7. UVLS and UFLS Relays that Comprise a Protection System Distributed Over the Power System

A. We have an Under Voltage Load Shedding (UVLS) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this standard?

The situation as stated indicates that the tripping action was intended to prevent low distribution voltage ~~for~~to a specific load from a transmission system that was intact except for the line that was out of service~~.~~, as opposed to preventing cascading outage or transmission system collapse.

This Standard is not applicable to this UVLS.

B. We have a UFLS scheme that sheds the necessary load through distribution-side circuit breakers and circuit reclosers. Do the trip-test requirements for circuit breakers apply to our situation?

No. Distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential Lock-Out Relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this standard.

C. What does "distributed over the power system" mean?

This refers to the common practice of applying UFLS on the distribution system, with each UFLS individually tripping a relatively low value of load. Therefore, the program is implemented via a large number of individual UFLS components performing independently, and the failure of any individual component to perform properly will have a minimal impact on the effectiveness of the overall UFLS program. Some UVLS systems are applied similarly.

8. SPS or Relay Sensing for Centralized UFLS or UVLS

A. Do I have to perform a full end-to-end test of a Special Protection System?

No. All portions of the SPS need to be maintained, and the portions must overlap, but the overall SPS does not need to have a single end-to-end test.

B. What about SPS interfaces between different entities or owners?

All SPS owners should have maintenance agreements that state which owner will perform specific tasks. As in all of the Protection System requirements, SPS segments can be tested individually~~, but must overlap.~~ thus minimizing the need to accommodate complex maintenance schedules.

C. What do I have to do if I am using a phasor measurement unit (PMU) as part of a Protection System or Special Protection System?

Any Phasor Measurement Unit (PMU) function whose output is used in a ~~protection system~~Protection System or Special Protection System (as opposed to a monitoring task) must be verified as a component in a Protection System.

D. How do I maintain a Special Protection System or Relay Sensing for Centralized UFLS or UVLS Systems?

~~Components~~ Since components of the SPS, UFLS, or UVLS are the same types of components as those in Protection Systems then these components should be maintained like similar components used for other Protection System functions. In many cases the devices for SPS, UFLS and UVLS are also used for other protective functions. The same maintenance activities apply with the exception that distributed systems (UFLS and UVLS) have fewer dc supply and control circuitry maintenance activity requirements.

For the testing of the output action, verification may be by breaker tripping, ~~or other control action that must be verified,~~ but may be verified in overlapping segments. ~~A grouped output control action need be verified only once within the specified~~ For example an SPS that trips a remote circuit breaker might be tested by testing the various parts of the scheme in overlapping segments. Another method is to document the real-time ~~interval, but all of the SPS, UFLS, or UVLS components whose operation leads to that control action must each be verified.~~tripping of an SPS scheme should that occur. Forced trip tests of circuit breakers (etc) that are a part of distributed UFLS or UVLS schemes are not required

E. What does "centralized" mean?

This refers to the practice of applying sensing units at many locations over the system, with all these components providing intelligence to an analytical system which then directs action to address a detected condition. In some cases, this action may not take place at the same location as the sensing units. This approach is often applied for complex SPS, and may be used for UVLS (and perhaps even with UFLS) where necessary to address the conditions of concern.

III Group by Type of BES Facility:

1. All BES Facilities

A. What, exactly, is the BES, or Bulk Electric System?

BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms Used in Reliability Standards, and is not being modified within this draft Standard.

NERC's approved definition of Bulk Electric System is:

> As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only load with one transmission source are generally not included in this definition.

Each Regional Entity implements a definition of the Bulk Electric System that is based on this NERC definition, in some cases, supplemented by additional criteria. These regional definitions have been documented and provided to FERC as part of a *June 16, 2007 Informational Filing*.

2. Generation

A. Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, and generator connected station auxiliary transformer to meet the requirements of this Maintenance Standard.

Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays

- Volts-per-hertz relays
- Negative sequence overcurrent relays
- Over voltage and under voltage protection relays
- Stator-ground relays
- Communications-based protection systems such as transfer-trip systems
- Generator differential relays
- Reverse power relays
- Frequency relays
- Out-of-step relays
- Inadvertent energization protection
- Breaker failure protection

For generator step up or generator-connected station auxiliary transformers, operation of any the following associated protective relays frequently would result in a trip of the generating unit and, as such, would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

A loss of a system-connected station auxiliary transformer could result in a loss of the generating plant if the plant was being provided with auxiliary power from that source, and this auxiliary transformer may directly affect the ability to start up the plant and to connect the plant to the system. Thus, operation of any of the following relays associated with system-connected station auxiliary transformers would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of the those loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program even if a trip of these devices might eventually result in a trip of the generating unit. For example, a thermal overcurrent trip on the motor of a coal-conveyor belt could eventually lead to the tripping of the generator, but it does not cause the trip.

3. Transmission

A. Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

IV Group by Type of Maintenance Program:

1. All Protection System Maintenance Programs

A. I can't figure out how to demonstrate compliance with the requirements for the highest level ~~3 (fully monitored)~~of monitoring of Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?

Demonstrating compliance with the requirements for ~~level 3 (fully monitored)~~the highest level of monitoring any particular component of Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This Standard does not presume to specify what documentation must be developed; only that it must be ~~comprehensive~~documented.

There may actually be some equipment available that is capable of meeting ~~level 3~~these highest levels of monitoring criteria, in which case it may be maintained according to ~~Table 1c~~the highest level of monitoring shown on the Tables. However, even if there is no equipment available today that can meet this level of monitoring~~,~~; the Standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the Standard technology-neutral. The standard drafting team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that are certainly coming to the industry.

B. What forms of evidence are acceptable?

Acceptable forms of evidence, as relevant for the Requirement being documented, include but are not limited to:

- Process documents or plans
- Data (such as relay settings sheets, photos, SCADA, and test records)
- Database lists, records and/or screen shots that demonstrate compliance information
- ~~Diagrams, engineering prints,~~Prints, diagrams and/or schematics~~, maintenance and testing~~
- Maintenance records~~, etc.~~
- Logs (operator, substation, and other types of log)
- Inspection forms
- ~~U.S. or Canadian mail~~Mail, memos, or email proving the required information was exchanged, coordinated, submitted or received
- ~~Database lists and records~~
- Check-off forms (paper or electronic)
- Any record that demonstrates that the maintenance activity was known~~ and~~, accounted for, and/or performed.

C. If I replace a failed Protection System component with another component, what testing do I need to perform on the new component?

The replacement component must be tested to a degree that assures that it will perform as intended. If it is desired to reset the Table 1 maintenance interval for the replacement component, all relevant Table 1 activities for the component should be performed.

D. Please use a specific example to demonstrate the data retention requirements.

The data retention requirements are intended to allow the availability of maintenance records to demonstrate that the time intervals in your maintenance plan were upheld. For example: “Company A” has a maintenance plan that requires its electro-mechanical protective relays be tested, for routine scheduled tests, every 3 calendar years with a maximum allowed grace period of an additional 18 months. This entity would be required to maintain its records of maintenance of its last two routine scheduled tests. Thus its test records would have a latest routine test as well as its previous routine test. The interval between tests is therefore provable to an auditor as being within “Company A’s” stated maximum time interval of 4.5 years.

The intent is not to ~~have~~require three test results proving two time intervals, but rather have two test results proving the last interval. The drafting team contends that this minimizes storage requirements while still having minimum data available to demonstrate compliance with time intervals.

Realistically, the Standard is providing advanced notice of audit team documentation requests; this type of information has already been requested by auditors.

If an entity prefers to utilize Performance Based Maintenance then statistical data may well be retained for extended periods to assist with future adjustments in time intervals.

2. Time-Based Protection System Maintenance (TBM) Programs

A. What does this Maintenance Standard say about commissioning? Is it necessary to have documentation in your maintenance history of the completion of commission testing?

This standard does not establish requirements for commission testing. Commission testing includes all testing activities necessary to conclude that a facility has been built in accordance with design. While a thorough commission testing program would include, either directly or indirectly, the verification of all those Protection System attributes addressed by the maintenance activities specified ~~on Table 1a~~in the Tables of PRC-005-2, verification of the adequacy of initial installation necessitates the performance of testing and inspections that go well beyond these routine maintenance activities. For example, commission testing might set baselines for future tests; perform acceptance tests and/or warranty tests; utilize testing methods that are not generally done routinely like staged-fault-tests.

However, many of the Protection System attributes which are verified during commission testing are not subject to age related or service related degradation and need not be re-verified within an ongoing maintenance program. Example – it is not necessary to re-verify correct terminal strip wiring on an ongoing basis.

PRC-005-2 assumes that thorough commission testing was performed prior to a protection system being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components such that a properly built and commission tested Protection System will continue to function as designed over its service life.

It should be noted that commission testing frequently is performed by a different organization than that which is responsible for the ongoing maintenance of the Protection System. Furthermore, the commission testing activities will not necessarily correlate directly with the maintenance activities required by the standard. As such, it is very likely that commission testing records will deviate significantly from maintenance records in both form and content and therefore, it is not necessary to maintain commission testing records within the maintenance program documentation.

~~An~~Notwithstanding the differences in records, an entity would be wise to retain commissioning records to show a maintenance start date. (See next FAQ).

B. How do you determine the initial due date for maintenance?

The initial due date for maintenance should be based upon when a facility and its associated Protection System were placed in service. Alternatively, an entity may choose to use the date of completion of the commission testing of the Protection System component as the starting point in determining its first maintenance due dates. Whichever method is chosen, for newly installed Protection Systems the maintenance program should clearly identify when maintenance is first due.

It is conceivable that there can be a (substantial) difference in time between the date of testing as compared to the date placed into service. The use of the “Calendar Year” language can help determine the next due date without too much concern about being non-compliant for missing test dates by a small amount (provided your dates are not already at the end of a year). However, if there is a substantial amount of time difference between testing and in-service dates then the testing date should be followed because it is the degradation of components that is the concern. While accuracy fluctuations may decrease when components are not energized there are cases when degradation can take place even though the device is not energized. Minimizing the time between commissioning tests and in-service dates will help.

C. The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?

No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals. The maintenance intervals were selected with typical plant outages, among other things, in mind.

D. If I am unable to complete the maintenance as required due to a major natural disaster (hurricane, earthquake, etc), how will this affect my compliance with this standard.

The ~~NERC~~ Sanction Guidelines of the North American Electric Reliability Corporation effective January 15, 2008 provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.~~[1]~~

E. What if my observed testing results show a high incidence of out-of-tolerance relays, or, even worse, I am experiencing numerous relay misoperations due to the relays being out-of-tolerance?

~~1 Sanction Guidelines of the North American Electric Reliability Corporation. Effective January 15, 2008.~~

~~Any~~The established maximum time intervals are mandatory only as a not-to-exceed limitation. The establishment of a maximum is measurable. But, any entity can choose to test some or all of their Protection System components more frequently (or, to express it differently, exceed the minimum requirements of the Standard). Particularly, if you find that the maximum intervals in the Standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently. A high incidence of relay Misoperations is in no one's best interest. The BES and an entity's bottom line both suffer.

F. We believe that the 3-month interval between inspections is unneccessary, why can we not perform these inspections twice per year?

The standard drafting team believes that routine monthly inspections are the norm. To align routine station inspections with other important inspections the 3-month interval was chosen. In lieu of station visits many activities can be accomplished with automated monitoring and alarming.

G. Our maintenance plan calls for us to perform routine protective relay tests every 3 years; if we are unable to achieve this schedule but we are able to complete the procedures in less than the Maximum Time Interval then are we in or out of compliance?

You are out of compliance. You must maintain your equipment to your stated intervals within your maintenance plan. The protective relays (and any Protection System component) cannot be tested at intervals that are longer than the maximum allowable interval stated in the Tables~~.~~ and yet you must conform to your own maintenance plan. Therefore you should design your maintenance plan such that it is not in conflict with the Minimum Activities and the Maximum Intervals. You then must maintain your equipment according to your maintenance plan. You will end up being compliant with both the standard and your own plan.

H. How do I achieve a "grace period" without being out of compliance?

For the purposes of this example, concentrating on just unmonitored protective relays, because there are more relays out there than anything else – Table 1-1 specifies a maximum time interval (between the mandated maintenance activities) of 6 calendar years. Your plan must ensure that your unmonitored relays are tested at least once every 6 calendar years. You could, within your PSMP, require that your unmonitored relays be tested every 4 calendar years with a maximum allowable time extension of 18 calendar months. This allows an entity to have deadlines set for the auto-generation of work orders but still have the flexibility in scheduling complex work schedules. This also allows for that 18 calendar months to act as a buffer, a grace period, in the event of unforeseen events. You will note that this example of a maintenance plan interval has a planned time of 4 years; it also has a built-in time extension allowed within the PSMP and yet does not exceed the maximum time interval allowed by the standard. So while there are no time extensions allowed beyond the standard, an entity can still have substantial flexibility to maintain their Protection System components.

I. If I miss two battery inspections four times out of 100 protection system components on my transmission system, does that count as 2 percent or 8 percent when counting Violation Severity Level (VSL) for R4?

The entity failed to complete its scheduled program on two of its one hundred protection system components which would equate to two percent for application to the VSL Table for Requirement R4.

3. Performance-Based Protection System Maintenance (PBM) Programs

A. I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?

Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for performance-based maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

B. Can an owner go straight to a performance-based maintenance program schedule, if they have previously gathered records?

Yes. An owner can go to a performance-based maintenance program immediately. The owner will need to comply with the requirements of a performance-based maintenance program as listed in the standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they ~~can not~~cannot prove that they have collected the data as required for a performance-based maintenance program then they will need to wait until they can prove compliance.

C. When establishing a performance-based maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my performance-based intervals?

No. You must use actual in-service test data for the components in the segment.

D. What types of misoperations or events are not considered countable events in the performance-based Protection System Maintenance (PBM) Program?

Countable events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned.

~~Human~~For this purpose of tracking hardware issues, human errors resulting in Protection System ~~Misoperations~~misoperations during system installation or maintenance activities are not considered countable events. Examples of excluded human errors include relay setting errors, design errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System components. Examples of misapplication of Protection System components include wrong CT or PT tap position, protective relay function misapplication, and components not specified correctly for their installation. Obviously, if one is setting up relevant data about hardware failures then human failures should be eliminated from the hardware performance analysis.

One example of human-error is not pertinent data might be in the area of testing "86" Lock-Out Relays (LOR). "Entity A" has two types of LOR's type "X" and type "Y"; they want to move into a performance based maintenance interval. They have 1000 of each type, so the population variables are met. During electrical trip testing of all of their various schemes over the initial six-year interval they find zero type "X" failures, but human error led to tripping a BES element 100 times; they find 100 type "Y" failures and had an additional 100 human-error caused tripping incidents. In this example the human-error caused misoperations should not be used to judge the performance of either type of LOR. Analysis of the data might lead "Entity A" to change time intervals. Type "X" LOR can be placed into extended time interval testing because of its low failure rate (zero failures) while Type "Y" would have to be tested more often than every 6 calendar years (100 failures divided by 1000 units exceeds the 4% tolerance level).

Certain types of Protection System component errors that cause ~~Misoperations~~misoperations are not considered countable events. Examples of excluded component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

E. What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance for mal-performing segments in a performance-based maintenance system. Some examples are listed below.

- The maximum allowable interval, as established by the performance-based maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment.
- Identifiable sub-groups of components within the established segment, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a performance-based maintenance program in order to remain within the program.
- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.
- Components within the mal-performing segment can be replaced with other components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

F. If I find (and correct) a maintenance-correctable issue as a result of a misoperation investigation (Re: PRC-004), how does this affect my performance-based maintenance program?

If you perform maintenance on a Protection System component for any reason (including as part of a PRC-004 required misoperation investigation/corrective action), the actions performed can count as a maintenance activity, and "reset the clock" on everything you've done. In a performance-based maintenance program, you also need to record the maintenance-correctable issue with the relevant component group and use it in the analysis to determine your correct performance-based maintenance interval for that component group. Note that "resetting the clock" should not be construed as interfering with an entity's routine testing schedule because the "clock-reset" would actually make for a decreased time interval by the time the next routine test schedule comes around.

For example a relay scheme, consisting of 4 relays, is tested on 1-1-11 and the PSMP has a time interval of 3 calendar years with an allowable extension of 1 calendar year. The relay would be due again for routine testing before the end of the year 2015. This mythical relay scheme has a misoperation on 6-1-12 that points to one of the four relays as bad. Investigation proves a bad relay and a new one is tested and installed in place of the original. This replacement relay actually could be retested before the end of the year 2016 (clock-reset) and not be out of compliance. This requires tracking maintenance by individual relays and is allowed. However, many companies schedule maintenance in other ways like by substation or by circuit breaker or by relay scheme. By these methods of tracking maintenance that "replaced relay" will be retested before the end of the year 2015. This is also acceptable. In no case was a particular relay tested beyond the PSMP of 4 years max, nor was the 6 year max of the standard exceeded. The entity can reset the clock if they desire or the entity can continue with original schedules and, in effect, test even more frequently.

G. Why are batteries excluded from PBM? What about exclusion of batteries from condition based maintenance?

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a performance-based Protection System Maintenance

(PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the electro-chemical process to completely isolate all of the performance-changing criteria.

Similarly Functional Entities that want to establish a condition-based maintenance program using ~~Level 3~~ the highest levels of monitoring; resulting in the least amount of hands-on maintenance activity, of the battery used in a station dc supply ~~can not do so~~cannot completely eliminate some periodic maintenance. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries. However, ~~Level 3~~higher degrees of monitoring of a battery can eliminate the requirement for some periodic testing and some inspections (see ~~Level 3 Monitoring Attributes for Component of table 1c~~Table 1-4).

H. Please provide an example of the calculations involved in extending maintenance time intervals using PBM.

Entity has 1000 GE-HEA lock-out relays; this is greater than the minimum sample requirement of 60

~~.~~ They start out testing all of the relays within the prescribed Table requirements (6 year max) by testing the relays every 5 years. The entity's plan is to test 200 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 6 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 6 failures in the 200 units tested. 6/200= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 10 years.

This represents a rate of 100 units tested per year; entity selects 100 units to be tested in the following year.

After that year of testing these 100 units the entity again finds 6 failed units. 6/100= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 8 years. This means that they will now test 125 units per year (1000/8). The entity has just two years left to get the test rate corrected.

After a year they again find 6 failures out of the 125 units tested. 6/125= 5% failures.

In response to the 5% failure rate, the entity decreases the testing interval to 7 years. This means that they will now test 143 units per year (1000/7). The entity has just one year left to get the test rate corrected.

After a year they again find 6 failures out of the 143 units tested. 6/143= 4.2% failures.

(Note that the entity has tried 5 years and they were under the 4% limit and they tried 7 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 5 years.)

Instead, in response to the 5% failure rate, the entity decreases the testing interval to 6 years. This means that they will now test 167 units per year (1000/6).

After a year they again find 6 failures out of the 167 units tested. 6/167= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 6 years or less. Entity chose 6 year interval and effectively extended their TBM (5 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the “5% of components” requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the “3 years” requirement; this is there to prevent an entity from “gaming the system”. An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	5 yrs	200	6	3%	Yes	10 yrs
2	1000	10 yrs	100	6	6%	Yes	8 yrs
3	1000	8 yrs	125	6	5%	Yes	7 yrs
4	1000	7 yrs	143	6	4.2%	Yes	6 yrs
5	1000	6 yrs	167	6	3.6%	No	6 yrs

V Group by Monitoring Level:

1. All Monitoring Levels

A. Please provide an example of the ~~level 1 monitored (~~unmonitored~~)~~ versus other levels of monitoring available?

~~A level 1 (Unmonitored)~~An unmonitored Protection System has no monitoring and alarm circuits on the Protection System components. A Protection System component that has monitoring attributes but no alarm output connected is considered to be un-monitored.

A ~~level 2 (Partially)~~ monitored Protection System or an individual monitored component of a ~~level 2 (Partially) monitored~~ Protection System has monitoring and alarm circuits on the Protection System components. The alarm circuits must alert, within 24 hours, a ~~24-hr staffed operations center~~location wherein corrective action can be initiated. This location might be, but not limited to an Operations Center, Dispatch Office, Maintenance Center or even a portable SCADA system.

There can be a combination of monitored and unmonitored Protection Systems within any given scheme, substation or plant; there can also be a combination of monitored and unmonitored components within any given Protection System.

Example #1: A combination of ~~level 2 (Partially)~~ monitored and ~~level 1 (~~unmonitored~~)~~ components within a given Protection System ~~is~~might be:

- ◊ A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center. (~~level 2~~monitored)
- ◊ Instrumentation transformers, with no monitoring, connected as inputs to that relay. (~~level 1~~unmonitored)
- ◊ A vented lead-acid battery with low voltage alarm and unintentional grounds detection alarm connected to SCADA. (monitored except for electrolyte level ~~2~~)
- ◊ A circuit breaker with a trip coil~~, with no monitor circuit. (level 1~~ and the trip circuit is not monitored. (unmonitored)

Given the particular components~~,~~ and conditions, and using the Table 1 (“Maximum Allowable Testing Intervals and Maintenance Activities”), the particular components have maximum activity intervals of:

- ◊ Every 3 calendar months check electrolyte level (cell voltage and unintentional ground detection is being maintained more frequently by the monitoring system).
- ◊ Every 18 calendar months check battery bank ohmic values (if performance tests are not opted), battery float voltage and battery rack integrity.
- ◊ Every 6 calendar years battery performance test (if ohmic tests are not opted), battery charger alarms verified and trip test circuit breakers, electro-mechanical lock-out relays and auxiliary relays.
- ◊ Every 12 calendar years the microprocessor relay, the instrumentation transformers and the control circuitry are verified.

Example #2: A combination of monitored and unmonitored components within a given Protection System might be:

- ◊ A microprocessor relay with integral alarm that is not connected to SCADA. (unmonitored)
- ◊ Instrument transformers, with no monitoring, connected as inputs to that relay. (monitored)
- ◊ A vented lead-acid battery with low voltage and ground-detection alarms connected to SCADA. (monitored except for electrolyte level)
- ◊ A circuit breaker with a trip coil, with no circuits monitored. (unmonitored)

Given the particular components and conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities"), the particular components have maximum ~~test~~activity intervals of:

- ◊ ~~The~~ Every 3 calendar months check electrolyte level (cell voltage and unintentional ground detection is being maintained more frequently by the monitoring system).
- ◊ Every 18 calendar months check battery bank ohmic values (if performance tests are not opted), battery float voltage and battery rack integrity.
- ◊ Every 6 calendar years microprocessor relay is verified ~~every 12 calendar years~~, battery performance test (if ohmic tests are not opted), battery charger alarms verified and trip test circuit breakers, electro-mechanical lock-out relays and auxiliary relays.
- ◊ ~~The~~ Every 12 calendar years the instrumentation transformers and the control circuitry are verified ~~every 12 calendar years.~~
- ~~◊ The battery is verified every 6 calendar years by performing a performance capacity test of the entire battery bank or by evaluating the measured cell/unit internal ohmic values to station battery baseline every 18 months.~~
- ◊ ~~The circuit breaker trip circuits and auxiliary relays are tested every 6 calendar years~~.

Example #~~2~~3: A combination of ~~level 2 (partially)~~ monitored and ~~level 1 (~~unmonitored~~)~~ components within a given Protection System ~~is:~~

- ~~◊ A microprocessor relay with integral alarm that is not connected to SCADA. (level 1)~~
- ~~◊ Instrument transformers, with no monitoring, connected as inputs to that relay. (level 1)~~
- ~~◊ A vented lead-acid battery with low voltage alarm connected to SCADA. (level 2)~~
- ~~◊ A circuit breaker with a trip coil, with no circuits monitored. (level 1)~~

~~Given the particular components, conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities"), the particular components have maximum test intervals of:~~

- ~~◊ The microprocessor relay is verified every 6 calendar years.~~
- ~~◊ The instrumentation transformers are verified every 12 calendar years.~~
- ~~◊ The battery is verified every 6 calendar years by performing a performance capacity test of the entire battery bank or by evaluating the measured cell/unit internal ohmic values to station battery baseline every 18 months.~~
- ~~◊ The circuit breaker trip circuits and auxiliary relays are tested every 6 calendar years.~~

~~**Example #3:** A combination of level 2 (partially) monitored and level 1 (unmonitored) components within a given Protection System is~~might be:

- ◊ A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center. (~~level 2~~monitored)
- ◊ Instrument transformers, with no monitoring, connected as inputs to that relay (~~level 1~~unmonitored)
- ◊ Battery without any alarms connected to SCADA (~~level 1~~unmonitored)
- ◊ Circuit breaker with a trip coil, with no circuits monitored (~~level 1~~unmonitored)

Given the particular components, conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities"), the particular components shall have maximum ~~test~~activity intervals of:

- ◊ ~~The~~ Every 3 calendar months check battery bank voltage, check for unintentional grounds and check electrolyte level.
- ◊ Every 18 calendar months check battery bank ohmic values (if performance tests are not opted), battery float voltage and battery rack integrity.
- ◊ Every 6 calendar years battery performance test (if ohmic tests are not opted), battery charger alarms verified and trip test circuit breakers, electro-mechanical lock-out relays and auxiliary relays.
- ~~◊~~ Every 12 calendar years the microprocessor relay ~~is verified every 12 calendar years.~~
- ~~◊ The instrument~~, the instrumentation transformers and the control circuitry are verified ~~every 12 calendar years.~~
- ~~◊ The battery is verified every 3 months, every 18 months, plus, depending upon the type of battery used it may be verified at other maximum test intervals, as well.~~
- ◊ ~~The circuit breaker trip circuits and auxiliary relays are tested every 6 calendar years~~.

B. What is the intent behind the different levels of monitoring?

The intent behind different levels of monitoring is to allow less frequent manual intervention when more information is known about the condition of Protection System components. Condition-Based Maintenance is a valuable asset to improve reliability.

C. Do all monitoring levels apply to all components in a protection system?

No. For some components in a protection system, certain levels of monitoring will not be relevant. ~~See table below:~~ For example a battery will always need some kind of inspection.

D. My microprocessor relays and dc circuit alarms are contained on relay panels in a 24-hour attended control room. Does this qualify as an extended time interval condition-based system?

Yes, provided the station attendant (plant operator, etc.) monitors the alarms and other indications (comparable to the monitoring attributes) and reports them within the given time limits that are stated in the criteria of the ~~Table 1b or Table 1c.~~

~~**Monitoring Level Applicability Table**~~Tables.

~~(See related definition and decision tree for various level requirements)~~

~~Protection Component~~	~~Level 1 (Unmonitored)~~	~~Level 2 (Partially Monitored)~~	~~Level 3 (Fully Monitored)~~
~~Protective relays~~	~~Y~~	~~Y~~	~~Y~~
~~Instrument transformer Inputs to Protective Relays~~	~~Y~~	~~N~~	~~Y~~
~~Protection System control circuitry (Other than aux-relays & lock-out relays)~~	~~Y~~	~~Y~~	~~Y~~
~~Aux-relays & lock-out relays~~	~~Y~~	~~N~~	~~N~~
~~DC supply (other than station batteries)~~	~~Y~~	~~Y~~	~~Y~~
~~Station batteries~~	~~Y~~	~~N~~	~~N~~
~~Protection system communications equipment and channels~~	~~Y~~	~~Y~~	~~Y~~
~~UVLS and UFLS relays that comprise a protection scheme distributed over the power system~~	~~Y~~	~~Y~~	~~Y~~
~~SPS, including verification of end-to-end performance, or relay sensing for centralized UFLS or UVLS systems~~	~~Y~~	~~Y~~	~~Y~~

~~Y = Monitoring Level Applies~~
~~N = Monitoring Level Not Applicable~~

E. When documenting the basis for inclusion of components into the appropriate levels of monitoring as per Requirement R2 of the standard, is it necessary to provide this documentation ~~via a~~about the device by ~~device~~ listing of ~~components~~every component and the specific monitoring attributes of each device?

No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a component type or portion thereof.
For example, it would be permissible to document the conclusion that all BES substation dc ~~systems are Level 2 – Partially~~supply battery chargers are Monitored by stating the following within the program description:

> "All substation dc ~~systems~~supply battery chargers are considered ~~Level 2 – Partially~~ Monitored and subject to the rows for monitored equipment of Table ~~1b~~1-4 requirements as all substation dc ~~systems~~supply battery chargers are equipped with dc

voltage alarms and ground detection alarms that are sent to the manned control center."

Similarly, it would be acceptable to use a combination of a global statement and a device level list of exclusions. Example:

"Except as noted below, all substation dc ~~systems~~supply battery chargers are considered ~~Level 2 - Partially~~ Monitored and subject to the rows for monitored equipment of Table ~~1b~~1-4 requirements as all substation dc ~~systems~~supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center. The dc ~~systems~~supply battery chargers of Substation X, Substation Y, and Substation Z are considered ~~Level 1 –~~ Unmonitored and subject to the rows for unmonitored equipment in Table ~~1a~~1-4 requirements as they are not equipped with ground detection capability."

Regardless whether this documentation is provided ~~via a device~~ by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure but should be retrievable if requested by an auditor.

~~**F. How do I know what monitoring level I am under? – Include Decision Trees**~~

~~Decision Trees are provided below for each of the following categories of equipment to assist in the determination of the level of monitoring.~~

- ~~Protective Relays~~
- ~~Current and Voltage Sensing Devices~~
- ~~Protection System Control Circuitry~~
- ~~Station dc Supply~~
- ~~Protection System Communication Systems~~

2. **~~Level 1 Monitored Protection Systems (~~Unmonitored Protection Systems ~~)~~**

   A. **We have an electromechanical (unmonitored) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer's high-side and low-side circuit breakers. What testing must be done for this system?**

   This system is made up of components that are ~~level 1 (~~all unmonitored~~)~~.. Assuming a time-based protection system maintenance program schedule~~,~~ (as opposed to a performance-based maintenance program), each component must be maintained per ~~Table 1a – Level 1 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities.~~the most frequent hands-on activities listed in the Tables 1-1 through 1-5.

3. **~~Level 2~~ Monitored Protection Systems ~~(Partially Monitored Protection Systems)~~**

   A. **We have a 30 year old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Is this an unmonitored or a partially-monitored system? How often must I perform maintenance?**

   The protective relay is ~~a level 2 (partially)~~ monitored ~~component of your protection system~~ and can be maintained every 12 years or when a maintenance correctable issue arises. ~~Assuming a time-based protection system maintenance program schedule, this component must be maintained per Table 1b – Level 2 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities~~ The control circuitry has no electro-mechanical parts and can be maintained every 12 years. The trip coil(s) has to be electrically operated at least once every 6 years.

   ~~The rest of your protection system contains components that are level 1 (unmonitored) and must be maintained within at least the maximum verification intervals of Table 1a.~~

   B. **How do I verify the A/D converters of microprocessor-based relays?**

   There are a variety of ways to do this. ~~Examples include~~ Two examples would be: using values gathered via data communications and automatically comparing these values with values from other sources, ~~and~~or using groupings of other measurements (such as vector summation of bus feeder currents) for comparison ~~if calibration requirements assure acceptable measurement of power system input values. Other~~. Many other methods are possible.

   C. **~~For a level 2 monitored Protection System (Partially Monitored Protection System) pertaining to~~How is the performance criteria of Protection System communications equipment ~~and channels, how is the performance criteria~~ involved in the maintenance program?**

~~The~~An entity determines the acceptable performance criteria ~~for each installation,~~ depending on the technology implemented. If the ~~communication~~communications channel performance of a Protection System varies from the pre-determined performance criteria for that system~~,~~ then these results should be investigated and resolved.

D. My system has alarms that are gathered once daily through an auto-polling system; this is not really a conventional SCADA system but does it meet the Table ~~1b~~1 requirements for inclusion as ~~Level 2~~a monitored system?

Yes, provided the auto-polling that gathers the alarms reports those alarms to a location where the action can be initiated to correct the maintenance-correctable issue. This location does not have to be the location of the engineer or the technician that will eventually repair the problem, but rather a location where the action can be initiated.

4. ~~Level 3~~ Monitored Protection Systems ~~(Fully Monitored Protection Systems)~~that also monitor alarm path failures

A. Why are there activities defined for levels of monitoring a ~~level 3 monitored~~ Protection System~~? The~~ component when that level of technology ~~does~~may not ~~seem to exist at this time to implement this monitoring level.~~yet be available?

There may ~~actually~~already be some equipment available that is capable of meeting ~~level 3~~the highest levels of monitoring criteria~~,~~ listed in ~~which case it may be maintained according to Table 1c~~the Tables. However, even if there is no equipment available today that can meet this level of monitoring~~;~~ the Standard establishes the necessary requirements for when such equipment becomes available. By creating a roadmap for development, this provision makes the Standard technology-neutral. The standard drafting team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that ~~are certainly~~may be coming to the industry.

PRC-005-2

Protection System Maintenance

Draft Supplementary Reference

November 17, 2010

Prepared by the

Protection System Maintenance and Testing Standard Drafting Team

PRC-005-2

Project 2007-17

Table of Contents

This supplementary reference to PRC-005-2 borrows heavily from the technical reference by the System Protection and Control Task Force (SPCTF) Protection System Maintenance Technical Reference paper approved by the Planning Committee in September 2007. Additionally, data available from IEEE, EPRI, and maintenance programs from various generation and transmission utilities across the NERC boundaries was utilized by the Protection System Maintenance and Testing Standard Drafting Team (PSMT SDT) for PRC-005-2 (Project 2007-17) to develop this reference document..

1. Introduction and Summary

NERC currently has four reliability standards that are mandatory and enforceable in the United States and address various aspects of maintenance and testing of Protection and Control systems. These standards are:

PRC-005-1 — *Transmission and Generation Protection System Maintenance and Testing*

PRC-008-0 — *Underfrequency Load Shedding Equipment Maintenance Programs*

PRC-011-0 — *UVLS System Maintenance and Testing*

PRC-017-0 — *Special Protection System Maintenance and Testing*

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs. This revision of PRC-005-1 combines and replaces PRC-005, PRC-008, PRC-011 and PRC-017.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a fault or other power system problem requires that they operate to protect power system elements, or even the entire Bulk Electric System (BES). Lacking faults or system problems, the protection systems may not operate for extended periods. A Misoperation - a false operation of a protection system or a failure of the protection system to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide area disturbances or unnecessary customer outages. Maintenance or testing programs are used to determine the performance and availability of protection systems.

Typically, utilities have tested protection systems at fixed time intervals, unless they had some incidental evidence that a particular protection system was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring relays, and correctness of settings. Typically, a protection system must be visited at its installation site and removed from service for this testing.

Fundamentally, a reliability standard for Protection System Maintenance and Testing requires the performance of the maintenance activities that are necessary to detect and correct plausible age and service related degradation of components such that a properly built and commissioned Protection System will continue to function as designed over its service life.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.

PRC-005-1 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms used in Reliability Standards indicates what must be included as a minimum.

Definition of *Protection System* (excerpted from the NERC Standards Glossary of Terms):

Protective relays, associated communications systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Proposed Modification to NERC Glossary Definition

The Protection Systems Maintenance and Testing Standard Drafting Team (PSM SDT), proposes changes to the NERC glossary definition of *Protection Systems* as follows:

Protection System (modification)

- Protective relays which respond to electrical quantities,
- communications systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:

"*...affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:

"*… and that are applied on, or are designed to provide protection for the BES.*"

The drafting team intends that this Standard will not apply to "merely possible" parallel paths, (sub-transmission and distribution circuits), but rather the standard applies to any Protection System that is designed to detect a fault on the BES and take action in response to that fault. The Standard Drafting Team does not feel that Protection Systems designed to protect distribution substation equipment are included in the scope of this standard; however, this will be impacted by the Regional definitions of the BES.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this standard applies are those relays that use measurements of voltage, current, frequency and/or phase angle and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.

3. Relay Product Generations

The likelihood of failure and the ability to observe the operational state of a critical protection system, both depends on the technological generation of the relays as well as how long they have been in service. Unlike many other transmission asset groups, protection and control systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices such as primary measuring relays, monitoring devices, control systems, and telecommunications equipment.

Modern microprocessor based relays have six significant traits that impact a maintenance strategy:

- Self monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs such as trip coil continuity. Most relay users are aware that these relays have self monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every element critical to the protection system must be monitored, or else verified periodically.
- Ability to capture fault records showing how the protection system responded to a fault in its zone of protection, or to a nearby fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-fault times. The relays can compute values such as MW and MVAR line flows that are sometimes used for operational purposes such as SCADA.
- Data communications via ports that provide remote access to all of the results of protection system monitoring, recording, and measurement.
- Ability to trip or close circuit breakers and switches through the protection system outputs, on command from remote data communications messages or from relay front panel button requests.
- Construction from electronic components some of which have shorter technical life or service life than electromechanical components of prior protection system generations.

4. Definitions

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- Restore — Return malfunctioning components to proper operation.

5. Time-Based Maintenance (TBM) Programs

Time-based maintenance is the process in which protection systems are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on protection system components. However, some components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire protection system tripping chain is able to operate the breaker.

Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed, and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the protection system has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components.

- PBM – performance-based maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

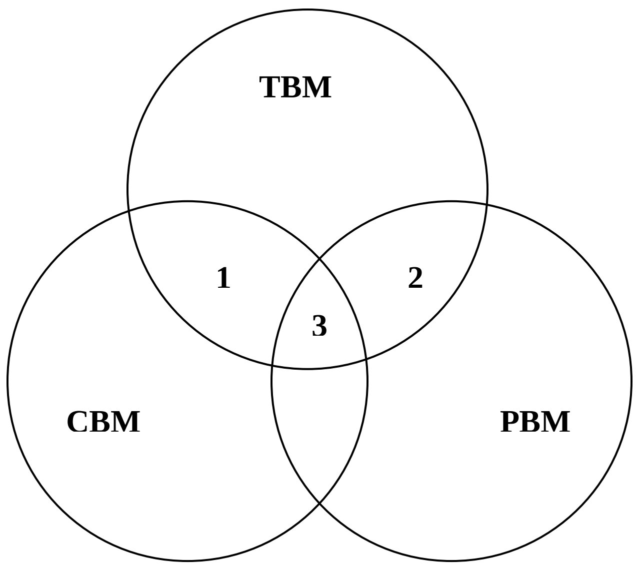
- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics.

  Microprocessor based protective relays that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include the ac signal inputs, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals. For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours or even milliseconds between non-disruptive self monitoring checks within or around components as they remain in service.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM. This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



Relationship of time-based maintenance types

5.1 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the protection system, when data on the reliability of the components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relay self monitoring, for example), the intervals may be extended or manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.

- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended while still achieving the desired level of performance. This is referred to as performance-based maintenance or PBM. It is also sometimes referred to as reliability-centered maintenance or RCM, but PBM is used in this document.

- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

6. Condition-Based Maintenance (CBM) Programs

Condition-based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor protection system elements. These relays and IEDs generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

1. Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in relay logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.
2. Information can come from event logs, captured files, and/or oscillograph records for faults and disturbances, metered values, and binary input status reports. Some of these are available on the relay front panel display, but may be available via data communications ports. Large files of fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the protection system.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

1. Non-invasive Maintenance: The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.
2. Virtually Continuous Monitoring: CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some relays will show health problems by incorrect relaying before being caught in the next test round. The frequent or continuous nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval.

7. Time-Based versus Condition-Based Maintenance

Time-based and condition-based maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time-based and condition-based maintenance.* The standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk Power System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-2. The defined time limits allow for longer time intervals if the maintained component is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the protection system owner knows about it, for the monitored segments of the protection system. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification, meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system components.

The result is that:

This NERC standard permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern protection systems to reduce the need for periodic site visits and invasive testing of components by on-site technicians. This periodic testing must be conducted within the maximum time intervals specified in Tables 1-1 through Tables 1-5 of PRC-005-2.

8. Maximum Allowable Verification Intervals

The Maximum Allowable Testing Intervals and Maintenance Activities show how CBM with newer relay types can reduce the need for many of the tests and site visits that older protection systems require. As explained below, there are some sections of the protection system that monitoring or data analysis may not verify. Verifying these sections of the Protection Systems requires some persistent TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities can be used to verify function of one tripping path and proper trip coil operation, if there has been no fault or routine operation to demonstrate performance of relay tripping circuits.

Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a time period of field installation. These tests may be used to ensure that individual components are still operating within acceptable performance parameters - this type of test is needed for components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total protection system functions from measurement of power system values, to properly identifying fault characteristics, to the operation of the interrupting devices.

8.1 Table of Maximum Allowable Verification Intervals

Table 1 (collectively known as Table 1, individually called out as Tables 1-1 through 1-5), in the standard, specifies maximum allowable verification intervals for various generations of protection systems and categories of equipment that comprise protection systems. The right column indicates maintenance activities required for each category.

The types of components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted line protection system comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows a typical Generation station layout. The various subsystems of a Protection System that need to be verified are shown. UFLS, UVLS, and SPS are additional categories of Table 1 that are not illustrated in these Figures. UFLS, UVLS and SPS all use identical equipment as Protection Systems in the performance of their functions and therefore have the same maintenance needs.

While it is easy to associate protective relays to multiple levels of monitoring, it is also true that most of the components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables from PRC-005-2:

- First find the Table associated with your component. The tables are arranged in the order of mention in the definition of Protection System; Table 1-1 is for protective relays, Table 1-2 is for the associated communications systems, Table 1-3 is for current and voltage sensing devices, Table 1-4 is for station dc supply and Table 1-5 is for control circuits. There is an additional table, Table 2, which brings alarms into the maintenance arena; this was broken out to simplify the other tables.
- Next look within that table for your device and its degree of monitoring. The tables have different hands-on maintenance activities prescribed depending upon the degree to which you monitor your equipment. Find the maintenance activity that applies to the monitoring level that you have on your piece of equipment.
- This Maintenance Activity is the minimum maintenance activity that must be documented.
- If your PSMP (plan) requires more activities then you must perform and document to this higher standard.
- After the maintenance activity is known, check the Maximum Maintenance Interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this component.
- If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to this higher standard.
- Any given component of a Protection System can be determined to have a degree of monitoring that may be different from another component within that same Protection System. For example, in a given Protection System it is possible for an entity to have a monitored protective relay and an unmonitored associated communications system; this combination would require hands-on maintenance activity on the relay at least once every 12 years and attention paid to the communications system as often as every 3 months.
- An entity does not have to utilize the extended time intervals made available by this use of condition-based monitoring. An easy choice to make is to simply utilize the unmonitored level of maintenance made available on each of the 5 Tables. While the maintenance activities resulting from this choice would require more maintenance man-hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System component, Table 1 shows maximum allowable testing intervals for the various degrees of monitoring. These degrees of monitoring, or levels, range from the legacy unmonitored through a system that is more comprehensively monitored.

It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-2. There may be any number of reasons that an entity chooses a more stringent plan than the minimums prescribed within PRC-005-2, most notable of which is an entity using performance based maintenance methodology. (Another reason for having a more stringent plan than is required could be a regional entity could have more stringent requirements.) Regardless of the rationale behind an entity's more stringent plan, it is incumbent upon them to perform the activities, and perform them at the stated intervals, of the entity's PSMP. A quality PSMP will help assure system reliability and adhering to any given PSMP should be the goal.

Additional Notes for Tables 1-1 through 1-5

1. For electro-mechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor-relays with no remote monitoring of alarm contacts, etc, are un-monitored relays and need to be verified within the Table interval as other un-monitored relays but may be verified as functional by means other than testing by simulated inputs.
2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs that are used as protective functions must be verified within the Table intervals.
3. Any Phasor Measurement Unit (PMU) function whose output is used in a protection system or SPS (as opposed to a monitoring task) must be verified as a component in a protection system.
4. In addition to verifying the circuitry that supplies dc to the protection system, the owner must maintain the station dc supply. The most widespread station dc supply is the station battery and charger. Unlike most Protection System components physical inspection of station batteries for signs of component failure, reduced performance, and degradation are required to ensure that the station battery is reliable enough to deliver dc power when required. IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner might use the applicable IEEE recommended practice which contains information and recommendations concerning the maintenance, testing and replacement of its substation battery. However, the methods prescribed in these IEEE recommendations cannot be specifically required because they do not apply to all battery applications.
5. Aggregated small entities might distribute the testing of the population of UFLS/UVLS systems, and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program. Thus these distributed systems have decreased requirements as compared to other Protection Systems.
6. Voltage & Current Sensing Device circuit input connections to the protection system relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected, (phase value and phase relationships are both equally important to verify).

7. Verify the protection system tripping function by performing an operational trip test on all components contained in the trip circuit. This includes circuit breaker or circuit switcher trip coils, auxiliary tripping relays (94), lock-out relays (86), and communications-assisted trip scheme elements. Each control circuit path that carries trip signal must be verified, although each path must be checked only once. A maintenance program may include performing an overall test for the entire system at one time, or several split system tests with overlapping trip verification. A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test.

8. "End-to-end test" as used in this supplementary reference is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can be interpreted as a GPS-type functional test it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc Control Circuitry. A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to verify each and every parallel trip path that participated in any given dc Control Circuit trip. Or, another possible solution is that a single trip path from a single monitored relay can be verified to be the trip path that successfully tripped during a real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.

9. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.

10. Notes 1-9 attempt to describe the testing activities they do not represent the only methods to achieve these activities but rather some possible methods. Technological advances, ingenuity and/or industry accepted techniques can all be used to satisfy maintenance activity requirements; the standard is technology and method neutral in most cases.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three year retention cycle, the records of verification for a protection system will typically be discarded before the next verification, leaving no record of what was done if a misoperation or failure is to be analyzed.

PRC-005-2 corrects this by requiring:

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous on-site audit date, whichever is longer

This requirement assures that the documentation shows that the interval between maintenance cycles correctly meets the maintenance interval limits. The requirement is actually alerting the industry to documentation requirements already implemented by audit teams. Evidence of compliance bookending the interval shows interval accomplished instead of proving only your planned interval.

8.3 Basis for Table 1 Intervals

SPCTF authors collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. SPCTF also reviewed the 2005 Report [2] of the IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. The survey represented 470 GW of peak load, or 64% of the NERC peak load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak load) of the reporting utility. Thus, the averages more accurately represent practices for the large populations of protection systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of 5 years for electromechanical or solid state relays, and 7 years for un-monitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond 7 years, based on favorable experience with the particular products they have installed. To provide a technical basis for such extension, SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1] as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1 only when such relays are monitored as specified in the attributes of monitoring contained in Tables 1-1 through 1-5 and Table 2. Monitoring is capable of reporting protection system health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, protection system availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve protection system availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades protection system availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for a monitored relay as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance – A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability - the probability that the relay is out of service due to failure or maintenance activity while the power system element to be protected is in service.
- Abnormal Unavailability - the probability that the relay is out of service due to failure or maintenance activity when a fault occurs, leading to failure to operate for the fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical ST values are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup fault clearing time of 50 cycles)

Rc, Protected component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a protection system)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a protection system repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for Relay Unavailability and Abnormal Unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years – the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.

PSMT SDT further notes that the SPCTF also allowed 25% extensions to the “maximum time intervals”. With a 5 year time interval established between manual maintenance activities and a 25% time extension then this equates to a 6.25 year maximum time interval. It is the belief of the PSMT SDT that the SPCTF understood that 6.25 years was thereby an adequate maximum time interval between manual maintenance activities. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. A 10 year interval with a 25% allowed extension equates to a maximum allowed interval of 12.5 years between manual maintenance activities. The Standard does not allow extensions on any component of the protection system; thus the maximum allowed interval for these components has been set to12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table’s use of the term “Calendar” in the column for “Maximum Maintenance Interval”. The PSMT SDT deemed it necessary to include the term “Calendar” to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term “Calendar” to preclude the need to have schedules be met to the day. An electro-mechanical protective relay that is maintained in year #1 need not be revisited until 6 years later (year #7). For example: a relay was maintained April 10, 2008; maintenance would need to be completed no later than December 31, 2014.

Section 9 describes a performance-based maintenance process which can be used to justify maintenance intervals other than those described in Table 1.

Section 10 describes sections of the protection system, and overlapping considerations for full verification of the protection system by segments. Segments refer to pieces of the protection system, which can range from a single device to a panel to an entire substation.

Section 11 describes how relay operating records can (but not required to) serve as a basis for verification, reducing the frequency of manual testing.

Section 13 describes how a cooperative effort of relay manufacturers and protection system users can improve the coverage of self-monitoring functions, leading to full monitoring of the bulk of the protection system, and eventual elimination of manual verification or testing.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a performance-based maintenance process may be used to establish maintenance intervals (*PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*). A performance-based maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a performance-based maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered protection systems in order to provide historical justification for intervals other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

Utilities with performance-based maintenance track performance of protection systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a performance-based maintenance program would serve the utility well in explaining to regulators and the public a misoperation leading to a major system outage event.

A performance-based maintenance program requires auditing processes like those included in widely used industrial quality systems (such as ***ISO 9001-2000, Quality management systems — Requirements;*** or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance-based Maintenance (PBM) program the asset owner must first sort the various Protection System components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of a grouping of Protection Systems or components of a consistent design standard or particular model or type from a single manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment and the remaining 30 from a clean environment. This PBM process cannot be applied to batteries but can be applied to all other components of a Protection System including (but not limited to) specific battery chargers, instrument transformers, trip coils and/or control circuitry (etc.).

9.1 Minimum Sample Size

Large Sample Size

An assumption that needs to be made when choosing a sample size is “the sampling distribution of the sample mean can be approximated by a normal probability distribution.” The Central Limit Theorem states: “In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large.” (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> “… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution.” (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)
>
> “If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation.” (Elementary Statistics - Picturing the World, Larson, Farber, 2003)
>
> “The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005)
>
> “… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection.” (Statistical Analysis for Business Decisions, Peters, Summers, 1968)

Error of Distribution Formula

Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a “Pass/Fail” format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:
B = bound on the error of distribution (allowable error)
z = standard error
π = expected failure rate
n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance-based Program

One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason the following assumptions are made:

B = 5%
z = 1.96 (This equates to a 95% confidence level)
π = 4%

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance-based Program

The number of components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%
z = 1.44 (85% confidence level)
π = 4%

Using the equation above, n=31.8.

Recommendation

Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended (and required within the standard):

Minimum Population Size to use Performance-based Maintenance Program = 60

Minimum Sample Size to evaluate Performance-based Program = 30.

Once the population segment is defined then maintenance must begin within the intervals as outlined for the device described in the Tables (Table 1-1 through Table 1-5). Time intervals can be lengthened provided the last year's worth of components tested (or the last 30 units maintained, whichever is more) had fewer than 4% countable events. It is notable that 4% is specifically chosen because an entity with a small population (60 units) would have to adjust its time intervals between maintenance if more than 1 countable event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a Misoperation.

The minimum number of units that can be tested in any given year is 5% of the population. Note that this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of countable events equals or exceeds 4% of the last year's tested components (or the last 30 units maintained, whichever is more) then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the countable events is less than 4%; this must be attained within three years.

This additional time period of three years to restore segment performance to <4% countable events is mandated to keep entities from "gaming the PBM system". It is believed that this requirement provides the economic disincentives to discourage asset owners from arbitrarily pushing the PBM time intervals out to up to 20 years without proper statistical data.

10. Overlapping the Verification of Sections of the Protection System

Tables 1-1 through 1-5 require that every protection system component be periodically verified. One approach is to test the entire protection scheme as a unit, from the secondary windings of voltage and current sources to breaker tripping. For practical ongoing verification, sections of the protection system may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification. See Appendix A of this Supplementary Reference for additional discussion on this topic.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a protection system may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time-based maintenance with appropriate maximum verification intervals for categories of equipment as given in the Tables 1-1 through 1-5;
- Full monitoring as described in Tables 1-1 through 1-5;
- A performance-based maintenance program as described in Section 9 above or Attachment A of the Standard;
- Opportunistic verification using analysis of fault records as described in Section 11

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve fault event records and oscillographic records by data communications after a fault. They analyze the data closely if there has been an apparent misoperation, as NERC standards require. Some advanced users have commissioned automatic fault record processing systems that gather and archive the data. They search for evidence of component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured digital fault recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on protection systems whose operations are analyzed. Even electromechanical protection systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of faults in the vicinity of the relay that produce relay response records, and the specific data captured.

A typical fault record will verify particular parts of certain protection systems in the vicinity of the fault. For a given protection system installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external fault records that completely verify the protection system.

For example, fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that fault. A relay or DFR record may indicate correct operation of the protection communications channel. Furthermore, other nearby protection systems may verify that they restrain from tripping for a fault just outside their respective zones of protection. The ensemble of internal fault and nearby external fault event data can verify major portions of the protection system, and reset the time clock for the Table 1 testing intervals for the verified components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity in the record and the associated wiring paths are verified. Be careful about using fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple faults close to either side of a setting boundary, setting or calibration could still be incorrect.
If fault record data is used to show that portions or all of a protection system have been verified to meet Table 1 requirements, the owner must retain the fault records used, and the maintenance related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

12. Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to protection system performance.

Monitoring does not check measuring element settings. Analysis of fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them. For background and guidance, see [5].

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple. With legacy relays (non-microprocessor protective relays) it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific requirement to maintain a settings management process there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.
- A relay is upgraded with a new firmware version.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed systems that are described as self-monitoring.

Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored or partially monitored intervals established in Table 1.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of full monitoring, the manufacturers of the microprocessor-based self-monitoring components in the protection system should publish for the user a document or map that shows:

- How all internal elements of the product are monitored for any failure that could impact protection system performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

With this information in hand, the user can document full monitoring for some or all sections by:

- Presenting or referencing the product manufacturer’s documents.
- Explaining in a system design document the mapping of how every component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission facilities through which failures are reported within a given time frame to allocate where action can be taken to initiate resolution of the alarm attributed to a maintenance correctable issue, so that failures of monitoring or alarming systems also lead to alarms and action.
- Documenting the plans for verification of any unmonitored components according to the requirements of Table 1.

14. Notification of Protection System Failures

When a failure occurs in a protection system, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC standard(s). Knowledge of the failure may impact the system operator’s decisions on acceptable loading conditions.

This formal reporting of the failure and repair status to the system operator by the protection system owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance but if its battery maintenance program is lacking then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific components. PRC-005-02 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore *manual intervention* to perform certain activities on these type components may not be needed.

15.1 Protective Relays (Table 1-1)

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted portion of the BES. Devices that sense thermal, vibration, seismic, pressure, gas or any other non-electrical inputs are excluded.

Non-microprocessor based equipment is treated differently than microprocessor based equipment in the following ways, the relays should meet the asset owners' tolerances.

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
  - There is no specific protective relay commissioning test or relay routine test mandated.
  - There is no specific documentation mandated.

15.2 Voltage & Current Sensing Devices (Table 1-3)

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are considered to be a type of voltage and current sensing devices included in this standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these components. The important thing about these signals is to know that the expected output from these components actually reaches the protective relay. Therefore, the proof of the proper operation of these components also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device all the way to the protective relay. The following observations apply.

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.
- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; by calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to verify the circuit meets the asset owner's protection system maintenance program.
- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this therefore tests the CT as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during load conditions, at the input to the relay.

- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the real-time loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay then the verification activity has been satisfied. Thus event reports (and oscillographs) can be used to verify that the voltage and current sensing devices are performing satisfactorily.
- Still another method is to measure total watts and vars around the entire bus; this should add up to zero watts and zero vars thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- Any other methods that provide documentation that the expected transformer values as applied to the inputs to the protective relays are acceptable.

15.3 Control circuitry associated with protective functions (Table 1-5)

This component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring (or other signal conveyance) from every trip output to every trip coil. It includes any device needed for the correct processing of the needed trip signal to the trip coil of the interrupting device; this requirement is meant to capture inputs and outputs to and from a protective relay that are necessary for the correct operation of the protective functions. In short, every trip path must be verified and every I/O path must be verified; the method of verification is optional to the asset owner. An example of testing methods to accomplish this might be to verify, with a volt-meter, the existence of the proper voltage at the open contacts, the open circuited input circuit and at the trip coil(s). As every parallel trip path has similar failure modes, each trip path from relay to trip coil must be verified. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once. There is a requirement to operate the circuit breaker (or other interrupting device) at least once every six years as part of the complete functional test. If a suitable monitoring system is installed that verifies every parallel trip path then the manual-intervention testing of those parallel trip paths can be extended beyond twelve years, however the actual operation of the circuit breaker must still occur at least once every six years. This 6-year tripping requirement can be completed as easily as tracking the real-time fault-clearing operations on the circuit breaker or tracking the trip coil(s) operation(s) during circuit breaker routine maintenance actions

The circuit-interrupting device should not be confused with a motor-operated disconnect. The intent of this standard is to require maintenance intervals and activities on Protection Systems equipment and not just all equipment.
It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device if this ground switch is utilized in a Protection System and forces a ground fault to occur that then results in an expected Protection System operation to clear the forced ground fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is "…applied on, or designed to provide protection for the BES…" then this device needs to be treated as any other Protection System component. The control circuitry would have to be tested within 12 years and any electromechanically operated device will have to be tested every 6 years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit then the solenoid triggering unit can easily be tested without the actual closing of the ground blade.

Circuit breakers that participate in a distributed UFLS or UVLS scheme are excluded from the tripping requirement, but not from the circuit test requirements; since the circuitry must be tested at least once every 12 years and the circuit interrupting device need not be tested then this effectively makes this a 12 year requirement. There are many circuit interrupting devices in the distribution system that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping-action of a single distributed system circuit breaker will be far less significant than, for example, any single Transmission Protection System failure such as a failure of a Bus Differential Lock-Out Relay. While many failures of these distributed system circuit breakers could add up to be significant, it is also believed that many circuit breakers are operated often on just fault clearing duty and therefore these circuit breakers are operated at least as frequently as any requirements that appear in this standard.

The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) that may exist in any particular trip scheme. If these devices are electro-mechanical components then they must be trip tested. The PSMT SDT considers these components to share some similarities in failure modes as electro-mechanical protective relays; as such there is a six year maximum interval between mandated maintenance tasks unless PBM is applied.

When verifying the operation of the 94 and 86 relays each normally-open contact that closes to pass a trip signal must be verified as operating correctly. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.

New technology is also accommodated here; there are some tripping systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment.

15.4 Batteries and DC Supplies (Table 1-4)

IEEE guidelines were consulted to arrive at the maintenance activities for batteries. The following guidelines were used: IEEE 450 (for Vented Lead-Acid batteries), IEEE 1188 (for Valve-Regulated Lead-Acid batteries) and IEEE 1106 (for Nickel-Cadmium batteries).

The currently proposed NERC definition of a Protection System is

- Protective relays which respond to electrical quantities,
- communications systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices." The station battery is not the only component that provides dc power to a Protection System. In the new definition for Protection System "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. An open battery string will be an unavailable power source in the event of loss of the battery charger.

Batteries cannot be a unique population segment of a Performance-based Maintenance Program (PBM) because there are too many variables in the electro-chemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery systems. However, nothing precludes the use of a PBM process for any other part of a dc supply besides the batteries themselves.

15.5 Associated communications equipment (Table 1-2)

The equipment used for tripping in a communications assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested.

Besides the trip output and wiring to the trip coil(s) there is also a communications medium that must be maintained.

Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology.

For example: older technologies may have included *Frequency Shift Key* methods. This technology requires that guard and trip levels be maintained.

The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests.

Emerging technologies transfer digital information over a variety of carrier mediums that are then interpreted locally as trip signals.

The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore this standard is applied to equipment used to convey both trip signals (permissive or direct) and block signals.

It was the intent of this standard to require that a test be made of any communications-assisted trip scheme regardless of the vintage of the technology. The essential element is that the tripping (or blocking) occurs locally when the remote action has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted.

Any evidence of operational test or documentation of measurement of signal level, reflected power or data-error rates can fulfill the requirements.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

15.6 Alarms (Table 2)

In addition to the tables of maintenance for the components of a Protection System, there is an additional table added for alarms. This additional table was added for clarity. This enabled the common alarm attributes to be consolidated into a single spot and thus make it easier to read the Tables 1-1 through 1-5. The alarms need to arrive at a site wherein a corrective action can be initiated. This could be a control room, operations center, etc. The alarming mechanism can be a standard alarming system or an auto-polling system, the only requirement is that the alarm be brought to the action-site within 24 hours. This effectively makes manned-stations equivalent to monitored stations. The alarm of a monitored point (for example a monitored trip path with a lamp) in a manned-station now makes that monitored point eligible for monitored status. Obviously, these same rules apply to a non-manned-station, which is that if the monitored point has an alarm that is auto-reported to the operations center (for example) within 24 hours then it too is considered monitored.

15.7 Examples of Evidence of Compliance

To comply with the requirements of this Standard an entity will have to document and save evidence. The evidence can be of many different forms. The Standard Drafting Team recognizes that there are concurrent evidence requirements of other standards that could, at times fulfill evidence requirements of this standard.

For example: maintaining evidence for operation of Special Protection Systems could concurrently be utilized as proof of the operation of the associated trip coil (provided one can be certain of the trip coil involved). Thus the reporting requirements that one may have to do for the mis-operation of a Special Protection Scheme under PRC-016 could work for the activity tracking requirements under this PRC-005-2.

Another example might be:

Some entities maintain records of all interruptions. These records can be concurrently utilized, if the entity desires, as DC Trip Path verifications.

Analysis of Event Recordings can provide details that can eliminate some hands-on maintenance activities; merely printing out the event report provides limited benefit of verification of specific maintenance items.

Standardized-forms, hard or soft copy, can be created, filled out and archived. These forms can be of the entities' design and can be aimed at answering the specific requirements of the Standard as well as additional requirements as needed by the entity.

Fill-in blanks, check-boxes, drop-down lists, auto-date formats, etc. can all be used as the primary action is the maintenance activity time interval; other techniques can be used to verify that the maintenance activity was performed, such as test reports.

Other evidence of compliance might be, but is not limited to:

Prints, maintenance plans, training materials, policies, procedures, data print-outs or exhibits, correspondence, reports, data-base records, etc.

There is the legacy method of paper trail for everything, this is acceptable. There are also paperless systems existing and evolving that are also acceptable.

Proof of compliance should simply be the entities' records of maintenance completed.

For information on components, see ***[Figure 1 & 2 Legend – Components of Protection Systems]***

([Return])

Figure 1 & 2 Legend – Components of Protection Systems

Number in Figure	Component of Protection System	Includes	Excludes
1	Protective relays which respond to electrical quantities	All protective relays that use current and/or voltage inputs from current & voltage sensors and that trip the 86, 94 or trip coil.	Devices that use non-electrical methods of operation including thermal, pressure, gas accumulation, and vibration. Any ancillary equipment not specified in the definition of Protection systems. Control and/or monitoring equipment that is not a part of the automatic tripping action of the Protection System
2	Voltage and current sensing devices providing inputs to protective relays	The signals from the voltage & current sensing devices to the protective relay input.	Voltage & current sensing devices that are not a part of the Protection System, including sync-check systems, metering systems and data acquisition systems.
3	control circuitry associated with protective functions	All control wiring (or other medium for conveying trip signals) associated with the tripping action of 86 devices, 94 devices or trip coils (from all parallel trip paths). This would include fiber-optic systems that carry a trip signal as well as hard-wired systems that carry trip current.	Closing circuits, SCADA circuits
4	Station dc supply	Batteries and battery chargers and any control power system which has the function of supplying power to the protective relays, associated trip circuits and trip coils.	Any power supplies that are not used to power protective relays or their associated trip circuits and trip coils.
5	Communications systems necessary for correct operation of protective functions	Tele-protection equipment used to convey specific information, in the form of analog or digital signals, necessary for the correct operation of protective functions.	Any communications equipment that is not used to convey information necessary for the correct operation of protective functions.

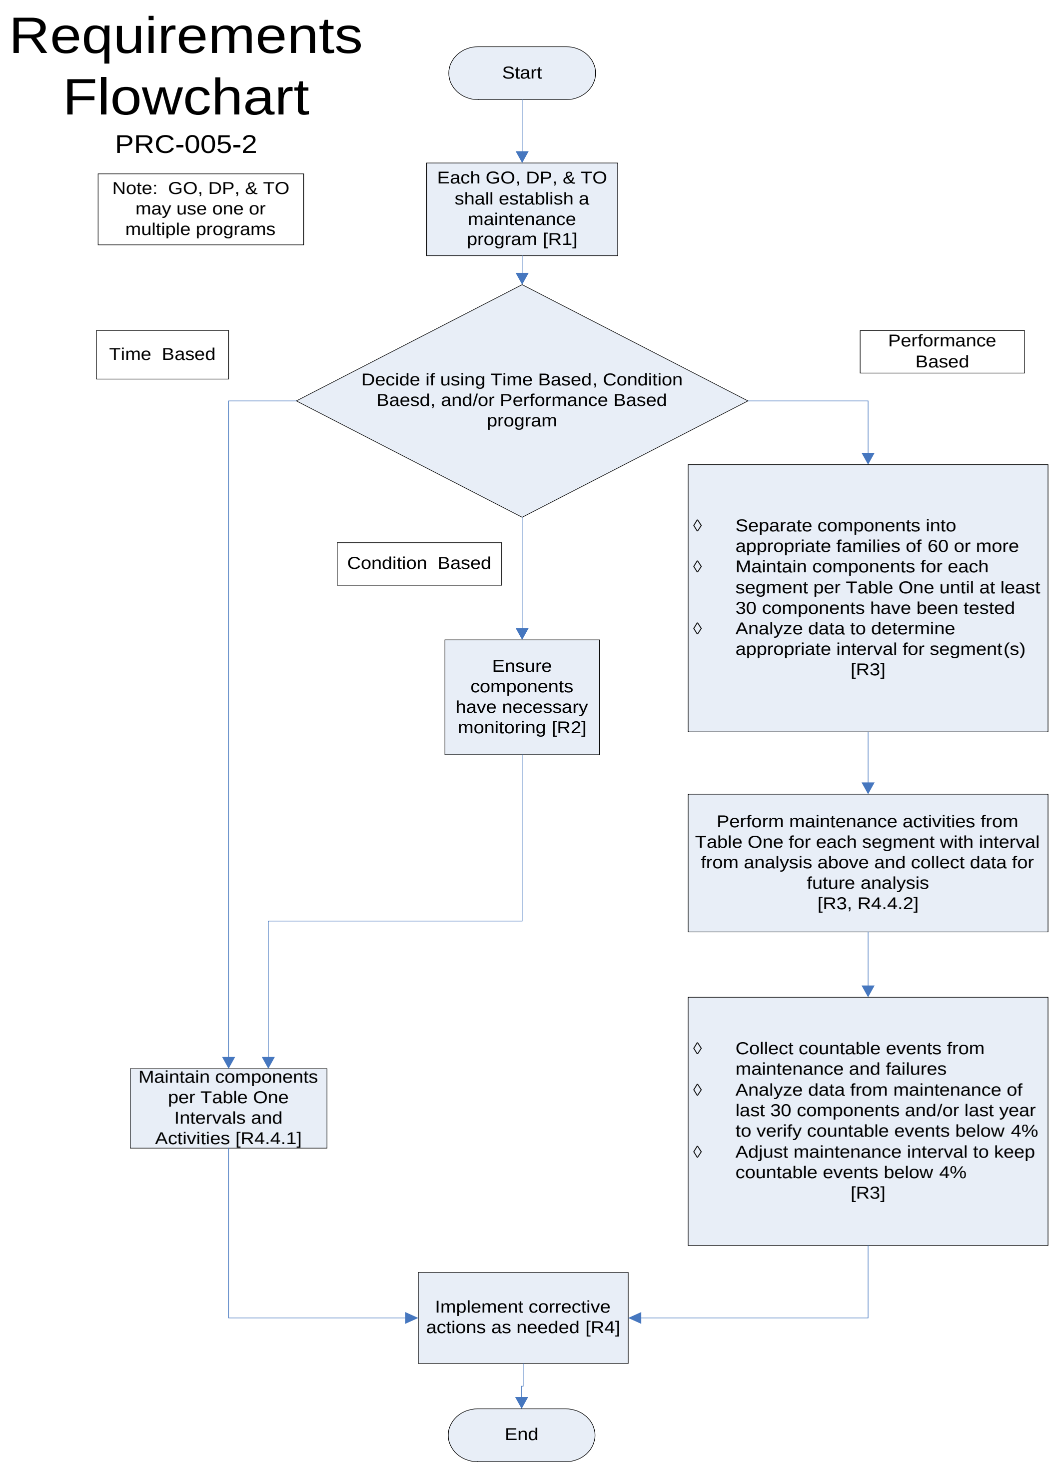
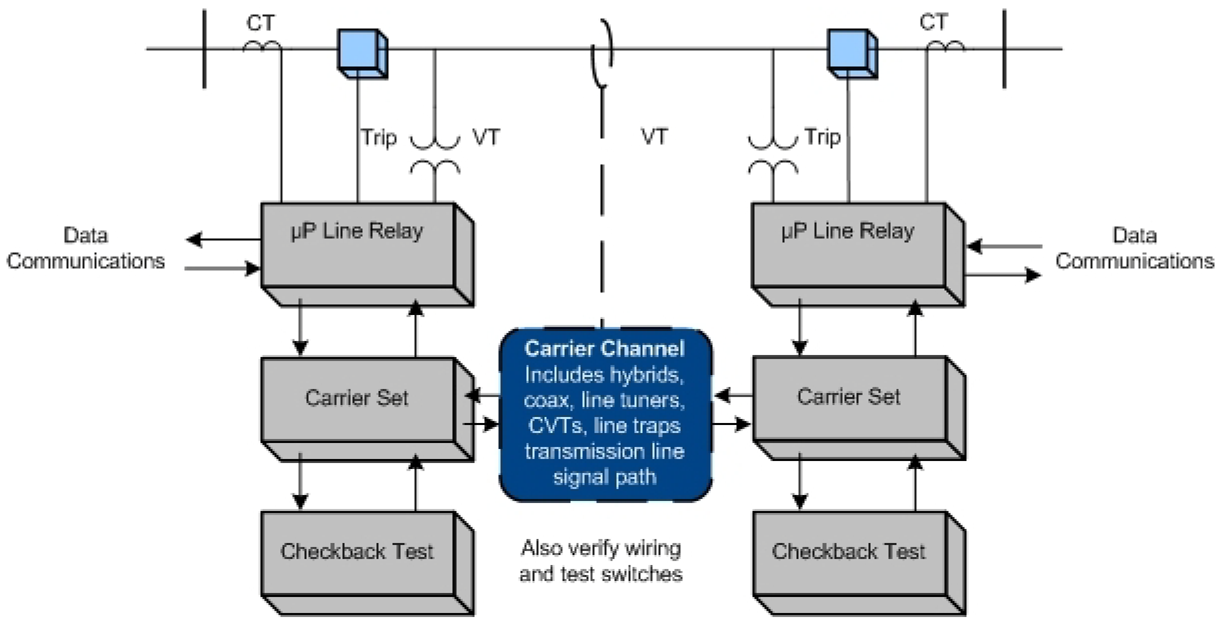
Figure 3: Requirements Flowchart



Appendix A

The following illustrates the concept of overlapping verifications and tests as summarized in Section 10 of the paper. As an example, Figure A-1 shows protection for a critical transmission line by carrier blocking directional comparison pilot relaying. The goal is to verify the ability of the entire two-terminal pilot protection scheme to protect for line faults, and to avoid over-tripping for faults external to the transmission line zone of protection bounded by the current transformer locations.

Figure A-1



In this example (Figure A1), verification takes advantage of the self-monitoring features of microprocessor multifunction line relays at each end of the line. For each of the line relays themselves, the example assumes that the user has the following arrangements in place:

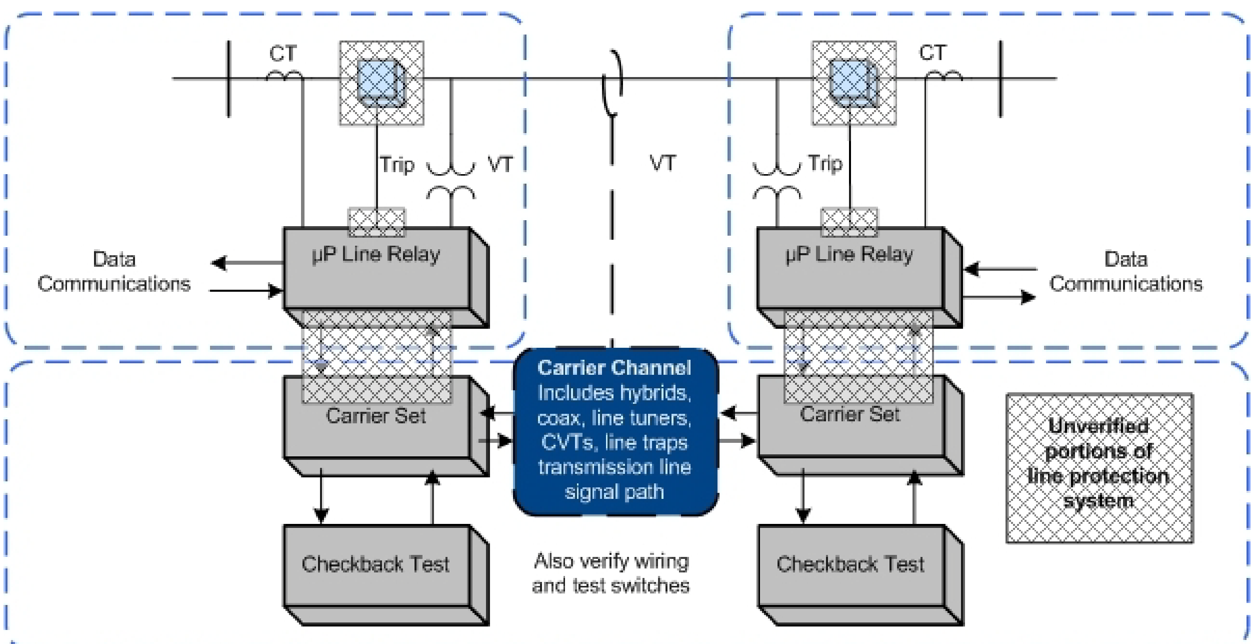
1. The relay has a data communications port that can be accessed from remote locations.
2. The relay has internal self-monitoring programs and functions that report failures of internal electronics, via communications messages or alarm contacts to SCADA.
3. The relays report loss of dc power, and the relays themselves or external monitors report the state of the dc battery supply.
4. The CT and PT inputs to the relays are used for continuous calculation of metered values of volts, amperes, plus Watts and VARs on the line. These metered values are reported by data communications. For maintenance, the user elects to compare these readings to those of other relays, meters, or DFRs. The other readings may be from redundant relaying or measurement systems or they may be derived from values in other protection zones. Comparison with other such readings to within required relaying accuracy verifies Voltage & Current Sensing

Devices, wiring, and analog signal input processing of the relays. One effective way to do this is to utilize the relay metered values directly in SCADA, where they can be compared with other references or state estimator values.

5. Breaker status indication from auxiliary contacts is verified in the same way as in (2). Status indications must be consistent with the flow or absence of current.
6. Continuity of the breaker trip circuit from dc bus through the trip coil is monitored by the relay and reported via communications.
7. Correct operation of the on-off carrier channel is also critical to security of the protection system, so each carrier set has a connected or integrated automatic checkback test unit. The automatic checkback test runs several times a day. Newer carrier sets with integrated checkback testing check for received signal level and report abnormal channel attenuation or noise, even if the problem is not severe enough to completely disable the channel.

These monitoring activities plus the check-back test comprise automatic verification of all the protection system elements that experience tells us are the most prone to fail. But, does this comprise a complete verification?

Figure A-2



The dotted boxes of Figure A-2 show the sections of verification defined by the monitoring and verification practices just listed. These sections are not completely overlapping, and the shaded regions show elements that are not verified:

1. The continuity of trip coils is verified, but no means is provided for validating the ability of the circuit breaker to trip if the trip coil should be energized.

2. Within each line relay, all the microprocessors that participate in the trip decision have been verified by internal monitoring. However, the trip circuit is actually energized by the contacts of a small telephone-type "ice cube" relay within the line protective relay. The microprocessor energizes the coil of this ice cube relay through its output data port and a transistor driver circuit. There is no monitoring of the output port, driver circuit, ice cube relay, or contacts of that relay. These components are critical for tripping the circuit breaker for a fault.
3. The check-back test of the carrier channel does not verify the connections between the relaying microprocessor internal decision programs and the carrier transmitter keying circuit or the carrier receiver output state. These connections include microprocessor I/O ports, electronic driver circuits, wiring, and sometimes telephone-type auxiliary relays.
4. The correct states of breaker and disconnect switch auxiliary contacts are monitored, but this does not confirm that the state change indication is correct when the breaker or switch opens.

A practical solution for (1) and (2) is to observe actual breaker tripping, with a specified maximum time interval between trip tests. Clearing of naturally-occurring faults are demonstrations of operation that reset the time interval clock for testing of each breaker tripped in this way. If faults do not occur, manual tripping of the breaker through the relay trip output via data communications to the relay microprocessor meets the requirement for periodic testing.

PRC-005 does not address breaker maintenance, and its protection system test requirements can be met by energizing the trip circuit in a test mode (breaker disconnected) through the relay microprocessor. This can be done via a front-panel button command to the relay logic, or application of a simulated fault with a relay test set. However, utilities have found that breakers often show problems during protection system tests. It is recommended that protection system verification include periodic testing of the actual tripping of connected circuit breakers.

Testing of the relay-carrier set interface in (3) requires that each relay key its transmitter, and that the other relay demonstrate reception of that blocking carrier. This can be observed from relay or DFR records during naturally occurring faults, or by a manual test. If the checkback test sequence were incorporated in the relay logic, the carrier sets and carrier channel are then included in the overlapping segments monitored by the two relays, and the monitoring gap is completely eliminated.

PRC-005-2

Protection System Maintenance

Draft Supplementary Reference

~~May 27~~November 17, 2010

Prepared by the

Protection System Maintenance and Testing Standard Drafting Team

PRC-005-2

Project 2007-17

Table of Contents

This supplementary reference to PRC-005-2 borrows heavily from the technical reference by the System Protection and Control Task Force (SPCTF) ~~(~~Protection System Maintenance Technical Reference paper approved by the Planning Committee in September 2007~~).~~. Additionally, data available from IEEE, EPRI, and maintenance programs from various generation and transmission utilities across the NERC boundaries was utilized by the Protection System Maintenance and Testing Standard Drafting Team (~~PSMTSDT~~PSMT SDT) for PRC-005-2 (Project 2007-17) ~~utilized maintenance program data from various generation and transmission utilities across the NERC boundaries; as well as data from IEEE and EPRI.~~to develop this reference document..

1. Introduction and Summary

NERC currently has four reliability standards that are mandatory and enforceable in the United States and address various aspects of maintenance and testing of Protection and Control systems. These standards are:

PRC-005-1 — *Transmission and Generation Protection System Maintenance and Testing*

PRC-008-0 — *Underfrequency Load Shedding Equipment Maintenance Programs*

PRC-011-0 — *UVLS System Maintenance and Testing*

PRC-017-0 — *Special Protection System Maintenance and Testing*

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs. This revision of PRC-005-1 combines and replaces PRC-005, PRC-008, PRC-011 and PRC-017.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a fault or other power system problem requires that they operate to protect power system elements, or even the entire Bulk Electric System (BES). Lacking faults or system problems, the protection systems may not operate for extended periods. A Misoperation - a false operation of a protection system or a failure of the protection system to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide area disturbances or unnecessary customer outages. ~~A maintenance~~ Maintenance or testing ~~program is~~programs are used to determine the performance and availability of protection systems.

Typically, utilities have tested protection systems at fixed time intervals, unless they had some incidental evidence that a particular protection system was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring relays, and correctness of settings. Typically, a protection system must be visited at its installation site and removed from service for this testing.

Fundamentally, a reliability standard for Protection System Maintenance and Testing requires the performance of the maintenance activities that are necessary to detect and correct plausible age and service related degradation of components such that a properly built and commissioned Protection System will continue to function as designed over its service life.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.

PRC-005-1 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms used in Reliability Standards indicates what must be included as a minimum.

Definition of *Protection System* (excerpted from the NERC Standards Glossary of Terms):

Protective relays, associated ~~communication~~communications systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Proposed Modification to NERC Glossary Definition

The Protection Systems Maintenance and Testing Standard Drafting Team (PSM SDT), proposes changes to the NERC glossary definition of *Protection Systems* as follows:

Protection System (modification)

- ~~–~~Protective relays~~, communication~~ which respond to electrical quantities,
- communications systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays~~ and associated circuitry from the voltage and current sensing devices, ,~~
- station ~~DC~~dc supply~~, and control circuitry,~~ associated with protective functions ~~from the~~(including station ~~DC~~batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:
"*...affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:
"*… and that are applied on, or are designed to provide protection for the BES.*"

The drafting team intends that this Standard will not apply to "merely possible" parallel paths, (sub-transmission and distribution circuits), but rather the standard applies to any Protection System that is designed to detect a fault on the BES and take action in response to that fault. The Standard Drafting Team does not feel that Protection Systems designed to protect distribution substation equipment are included in the scope of this standard; however, this will be impacted by the Regional definitions of the BES.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this standard applies are those relays that use measurements of voltage, current, frequency and/or phase angle and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.

3. Relay Product Generations

The likelihood of failure and the ability to observe the operational state of a critical protection system, both depends on the technological generation of the relays as well as how long they have been in service. Unlike many other transmission asset groups, protection and control systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices such as primary measuring relays, monitoring devices, control systems, and telecommunications equipment.

Modern microprocessor based relays have six significant traits that impact a maintenance strategy:

- Self monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs such as trip coil continuity. Most relay users are aware that these relays have self monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every element critical to the protection system must be monitored, or else verified periodically.
- Ability to capture fault records showing how the protection system responded to a fault in its zone of protection, or to a nearby fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-fault times. The relays can compute values such as MW and MVAR line flows that are sometimes used for operational purposes such as SCADA.
- Data communications via ports that provide remote access to all of the results of protection system monitoring, recording, and measurement.
- Ability to trip or close circuit breakers and switches through the protection system outputs, on command from remote data communications messages or from relay front panel button requests.
- Construction from electronic components some of which have shorter technical life or service life than electromechanical components of prior protection system generations.

4. Definitions

Protection System Maintenance Program (PSMP) ~~–~~— An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

~~An ongoing program by which Protection System components are kept in working order and where malfunction components are restored to working order~~

- ~~**Verification** – A means of determining~~Verify — Determine that the component is functioning correctly.
- ~~**Monitoring** – Observation of~~Monitor — Observe the routine in-service operation of the component.

- ~~**Testing** – Application of~~Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- ~~**Inspection** – To detect~~Inspect — Detect visible signs of component failure, reduced performance and degradation.
- ~~**Calibration** – Adjustment of~~Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

- ~~**Upkeep** – Routine activities necessary to assure that the component remains in good working order and implementation of any manufacturer's hardware and software service advisories which are relevant to the application of the device.~~

- ~~**Restoration** – The actions to restore proper operation of~~Restore — Return malfunctioning components~~.~~ to proper operation.

5. Time-Based Maintenance (TBM) Programs

Time-based maintenance is the process in which protection systems are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on protection system components. However, some components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire protection system tripping chain is able to operate the breaker.

Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed, and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the protection system has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock ~~is~~can be reset for those components.

- PBM – performance-based maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

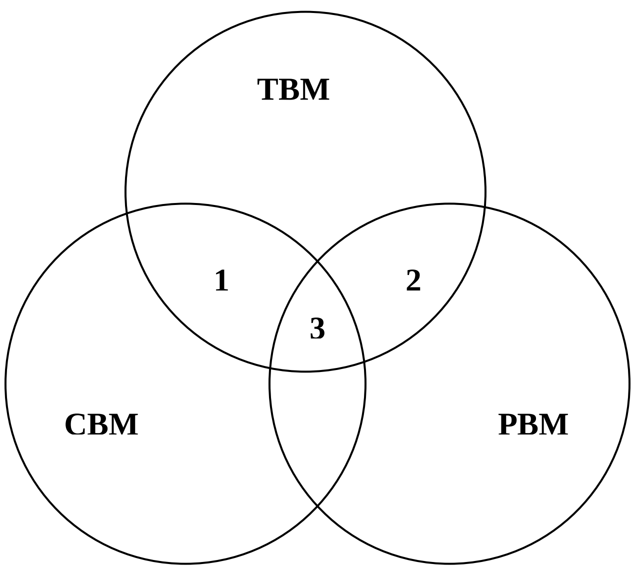
- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics.

Microprocessor based protective relays that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include the ac signal inputs, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals. For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours or even milliseconds between non-disruptive self monitoring checks within or around components as they remain in service.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM. This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



Relationship of time-based maintenance types

5.1 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the protection system, when data on the reliability of the components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relay self monitoring, for example), the intervals may be extended or manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.
- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended while still achieving the desired level of performance. This is referred to as performance-based maintenance or PBM. It is also sometimes referred to as reliability-centered maintenance or RCM, but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

6. Condition-Based Maintenance (CBM) Programs

Condition-based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor protection system elements. These relays and IEDs generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

1. Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in relay logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.
2. Information can come from event logs, captured files, and/or oscillograph records for faults and disturbances, metered values, and binary input status reports. Some of these are available on the relay front panel display, but may be available via data communications ports. Large files of fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the protection system.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

1. Non-invasive Maintenance: The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.

2. Virtually Continuous Monitoring: CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some relays will show health problems by incorrect relaying before being caught in the next test round. The frequent or continuous nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval.

7. Time-Based versus Condition-Based Maintenance

Time-based and condition-based maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time-based and condition-based maintenance.* The standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk Power System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-2. The defined time limits allow for longer time intervals if the maintained ~~device~~component is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the protection system owner knows about it, for the monitored segments of the protection system. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification ~~(as specified in the header and the "Monitoring Attributes" column of Tables 1b and 1c of PRC-005-2),~~, meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system ~~elements as contained in Table 1a~~components.

The result is that:

This NERC ~~standards~~standard permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern protection systems to reduce the need for periodic site visits and invasive testing of components by on-site technicians. This periodic testing must be conducted within the maximum time intervals specified in Tables ~~1a, 1b and 1c~~1-1 through Tables 1-5 of PRC-005-2.

8. Maximum Allowable Verification Intervals

The Maximum Allowable Testing Intervals and Maintenance Activities ~~requirements~~ show how CBM with newer relay types can reduce the need for many of the tests and site visits that older protection systems require. As explained below, there are some sections of the protection system that monitoring or data analysis may not verify. Verifying these sections of the Protection Systems requires some persistent

TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities can be used to verify function of one tripping path and proper trip coil operation, if there has been no fault or routine operation to demonstrate performance of relay tripping circuits.

Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a time period of field installation. These tests may be used to ensure that individual components are still operating within acceptable performance parameters - this type of test is needed for components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total protection system functions from measurement of power system values, to properly identifying fault characteristics, to the operation of the interrupting devices.

8.1 Table of Maximum Allowable Verification Intervals

Table 1~~,~~ (collectively known as Table 1, individually called out as Tables 1-1 through 1-5), in the standard, specifies maximum allowable verification intervals for various generations of protection systems and categories of equipment that comprise protection systems. The right column indicates maintenance activities required for each category.

The types of components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted line protection system comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows a typical Generation station layout. The various subsystems of a Protection System that need to be verified are shown. UFLS, UVLS, and SPS are additional categories of Table 1 that are not illustrated in these Figures. UFLS, UVLS and SPS all use identical equipment as Protection Systems in the performance of their functions and therefore have the same maintenance needs.

While it is easy to associate protective relays to ~~the three~~multiple levels of monitoring, it is also true that most of the components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables ~~(Tables 1a, 1b and 1c collectively *Tables*)~~ from PRC-005-2:

- ~~First check the table header description to verify that your equipment meets the monitoring requirements. If your equipment does not meet the monitoring requirements of Table 1c then check Table 1b. If your equipment does not meet the requirements of Table 1b then use Table 1a.~~
- ~~If you find a piece of equipment that meets the monitoring requirements of Table 1b or 1c then you can take advantage of the extended time intervals allowed by Table 1b and 1c. Your maintenance plan must document that this component can be maintained by the requirements of Table 1b or 1c because it has the necessary attributes required within that Table.~~
- ~~Once you determine which table applies to your equipment's monitoring requirements then check the Maintenance Activity that is required for that particular component.~~ First find the Table associated with your component. The tables are arranged in the order of mention in the definition of Protection System; Table 1-1 is for protective relays, Table 1-2 is for the associated communications systems, Table 1-3 is for current and voltage sensing devices, Table 1-4 is for station dc supply and Table 1-5 is for control circuits. There is an additional table, Table 2, which brings alarms into the maintenance arena; this was broken out to simplify the other tables.
- Next look within that table for your device and its degree of monitoring. The tables have different hands-on maintenance activities prescribed depending upon the degree to which you monitor your

equipment. Find the maintenance activity that applies to the monitoring level that you have on your piece of equipment.

- This Maintenance Activity is the minimum maintenance activity that must be documented.
- If your PSMP (plan) requires more activities then you must perform and document ~~more~~to this higher standard.
- After the maintenance activity is known, check the Maximum Maintenance Interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this component.
- If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities ~~more often~~to this higher standard.
- Any given ~~set~~component of a Protection System ~~equipment~~ can be ~~maintained with any combination of Tables 1a, 1b and 1c. An entity does not~~ determined to have ~~to stick to Table 1a just because some of its equipment~~a degree of monitoring that may be different from another component within that same Protection System. For example, in a given Protection System it is ~~un~~-possible for an entity to have a monitored protective relay and an unmonitored associated communications system; this combination would require hands-on maintenance activity on the relay at least once every 12 years and attention paid to the communications system as often as every 3 months.
- An entity does not have to utilize the extended time intervals ~~in Tables 1b or 1c~~made available by this use of condition-based monitoring. An easy choice to make is to simply utilize ~~Table 1a.~~the unmonitored level of maintenance made available on each of the 5 Tables. While the maintenance activities resulting from ~~choosing to use only Table 1a~~this choice would require more maintenance man-hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System component, Table 1 shows maximum allowable testing intervals for ~~unmonitored, partially monitored and fully monitored protection systems:~~the various degrees of monitoring. These degrees of monitoring, or levels, range from the legacy unmonitored through a system that is more comprehensively monitored.

~~Table 1 Maximum Allowable Testing Intervals and Maintenance Activities~~

~~Level 1 Monitoring (Unmonitored) Table 1a~~

~~This table applies to electromechanical, analog solid state and other un-monitored Protection Systems components. This table represents the starting point for all required maintenance activities. The object of this group of requirements is to have specific activities accomplished at maximum set time intervals. From this group of activities it follows that CBM or PBM can increase the time intervals between the hands-on maintenance actions.~~

~~Level 2 Monitoring (Partially Monitored) Table 1b~~

~~This table applies to microprocessor relays and other associated Protection System components whose self-monitoring alarms are transmitted to a location (at least daily) where action can be taken for alarmed failures. The attributes of the monitoring system must meet the requirements specified in the header of the Table 1b. Given these advanced monitoring capabilities, it is known that there are specific and routine testing functions occurring within the device. Because of this ongoing monitoring hands-on action is required less often because routine testing is automated. However, there is now an additional task that must be accomplished during the hands-on process – the monitoring and alarming functions must be shown to work.~~

~~*Level 3 Monitoring (Fully Monitored) Table 1c*~~

~~This table applies to microprocessor relays and other associated Protection System components in which every element or function required for correct operation of the Protection System component is monitored continuously and verified, including verification of the means by which failure alarms or indicators are transmitted to a location within 1 hour or less of the maintenance-correctable issue occurring. This is the highest level of monitoring and if it is available then this gives an entity the ability to have continuous testing of their (Level 3 Monitored) Protection System Component and thus does not have to manually intervene to accomplish routine testing chores. Level 3 Fully Monitored yields continuous monitoring advantages but has substantial technical hurdles that must be overcome; namely that monitoring also verifies the failure of the monitoring and alarming equipment. Without this important ingredient a device that is thought to be continuously monitored could be in an alarm state without the asset owner being aware of this alarm state.~~

It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-2. There may be any number of reasons that an entity chooses a more stringent plan than the minimums prescribed within PRC-005-2, most notable of which is an entity using performance based maintenance methodology. (Another reason for having a more stringent plan than is required could be a regional entity could have more stringent requirements.) Regardless of the rationale behind an entity's more stringent plan, it is incumbent upon them to perform the activities, and perform them at the stated intervals, of the entity's PSMP. A quality PSMP will help assure system reliability and adhering to any given PSMP should be the goal.

Additional Notes for ~~Table 1a, Table 1b, and Table 1c~~Tables 1-1 through 1-5

1. For electro-mechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor-relays with no remote monitoring of alarm contacts, etc, are un-monitored relays and need to be verified within the Table interval as other un-monitored relays but may be verified as functional by means other than testing by simulated inputs.
2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs that are used as protective functions must be verified within the Table intervals.
3. Any Phasor Measurement Unit (PMU) function whose output is used in a protection system or SPS (as opposed to a monitoring task) must be verified as a component in a protection system.
4. In addition to verifying the circuitry that supplies dc to the protection system, the owner must maintain the station dc supply. The most widespread station dc supply is the station battery and charger. Unlike most Protection System ~~elements~~components physical inspection of station batteries for signs of component failure, reduced performance, and degradation are required to ensure that the station battery is reliable enough to deliver dc power when required. IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner might use the applicable IEEE recommended practice which contains information and recommendations concerning the maintenance, testing and replacement of its substation battery. However, the methods prescribed in these IEEE recommendations cannot be specifically required because they do not apply to all battery applications.

5. Aggregated small entities might distribute the testing of the population of UFLS/UVLS systems, and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program. Thus these distributed systems have decreased requirements as compared to other Protection Systems.

6. Voltage & Current Sensing Device circuit input connections to the protection system relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected, (phase value and phase relationships are both equally important to verify).

7. Verify the protection system tripping function by performing an operational trip test on all components contained in the trip circuit. This includes circuit breaker or circuit switcher trip coils, auxiliary tripping relays (94), lock-out relays (86), and communications-assisted trip scheme elements. Each control circuit path that carries trip signal must be verified, although each path must be checked only once. A maintenance program may include performing an overall test for the entire system at one time, or several split system tests with overlapping trip verification. A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test.

8. "End-to-end test" as used in this supplementary reference is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can be interpreted as a GPS-type functional test it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc Control Circuitry. A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to verify each and every parallel trip path that participated in any given dc Control Circuit trip. Or, another possible solution is that a single trip path from a single monitored relay can be verified to be the trip path that successfully tripped during a real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.

9. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.

10. Notes 1-9 attempt to describe the testing activities they do not represent the only methods to achieve these activities but rather some possible methods. Technological advances, ingenuity and/or industry accepted techniques can all be used to satisfy maintenance activity requirements; the standard is technology and method neutral in most cases.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three year retention cycle, the records of verification for a protection system will typically be discarded before the next verification, leaving no record of what was done if a ~~Misoperation~~misoperation or failure is to be analyzed.

PRC-005-2 corrects this by requiring:

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous on-site audit date, whichever is longer~~.~~

This requirement assures that the documentation shows that the interval between maintenance cycles correctly meets the maintenance interval limits. The requirement is actually alerting the industry to documentation requirements already implemented by audit teams. Evidence of compliance bookending the interval shows interval accomplished instead of proving only your planned interval.

8.3 Basis for Table 1 Intervals

SPCTF authors collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. SPCTF also reviewed the 2005 Report [2] of the IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. The survey represented 470 GW of peak load, or 64% of the NERC peak load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak load) of the reporting utility. Thus, the averages more accurately represent practices for the large populations of protection systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of 5 years for electromechanical or solid state relays, and 7 years for un-monitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond 7 years, based on favorable experience with the particular products they have installed. To provide a technical basis for such extension, SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1] as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1 only when such relays are monitored as specified in the ~~header~~attributes of monitoring contained in Tables 1-1 through 1-5 and Table ~~1b~~2. Monitoring is capable of reporting protection system health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, protection system availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve protection system availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades protection system availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for ~~partial monitoring~~a monitored relay as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance – A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability - the probability that the relay is out of service due to failure or maintenance activity while the power system element to be protected is in service.
- Abnormal Unavailability - the probability that the relay is out of service due to failure or maintenance activity when a fault occurs, leading to failure to operate for the fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical ST values are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup fault clearing time of 50 cycles)

Rc, Protected component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a protection system)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a protection system repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for Relay Unavailability and Abnormal Unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years – the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.

PSMT SDT further notes that the SPCTF also allowed 25% extensions to the "maximum time intervals". With a 5 year time interval established between manual maintenance activities and a 25% time extension then this equates to a 6.25 year maximum time interval. It is the belief of the PSMT SDT that the SPCTF understood that 6.25 years was thereby an adequate maximum time interval between manual maintenance activities. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. A 10 year interval with a 25% allowed extension equates to a maximum allowed interval of 12.5 years between manual maintenance activities. The Standard does not allow extensions on any component of the protection system; thus the maximum allowed interval for these ~~devices~~components has been set to12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table's use of the term "Calendar" in the column for "Maximum Maintenance Interval". The PSMT SDT deemed it necessary to include the term "Calendar" to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term "Calendar" to preclude the need to have schedules be met to the day. An electro-mechanical protective relay that is maintained in year #1 need not be revisited until 6 years later (year #7). For example: a relay was maintained April 10, 2008; maintenance would need to be completed no later than December 31, 2014.

Section 9 describes a performance-based maintenance process which can be used to justify maintenance intervals other than those described in Table 1.

Section 10 describes sections of the protection system, and overlapping considerations for full verification of the protection system by segments. Segments refer to pieces of the protection system, which can range from a single device to a panel to an entire substation.

Section 11 describes how relay operating records can (but not required to) serve as a basis for verification, reducing the frequency of manual testing.

Section 13 describes how a cooperative effort of relay manufacturers and protection system users can improve the coverage of self-monitoring functions, leading to full monitoring of the bulk of the protection system, and eventual elimination of manual verification or testing.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a performance-based maintenance process may be used to establish maintenance intervals (*PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*). A performance-based maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a performance-based maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered protection systems in order to provide historical justification for intervals other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

Utilities with performance-based maintenance track performance of protection systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a performance-based maintenance program would serve the utility well in explaining to regulators and the public a ~~Misoperation~~misoperation leading to a major system outage event.

A performance-based maintenance program requires auditing processes like those included in widely used industrial quality systems (such as ***ISO 9001-2000, Quality management systems — Requirements;*** or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance-based Maintenance (PBM) program the asset owner must first sort the various Protection System components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of ~~like devices~~a grouping of Protection Systems or components of a consistent design standard or particular model or type from ~~the same~~a single manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment and the remaining 30 from a clean environment. This PBM process cannot be applied to batteries but can be applied to all other components of a Protection System including (but not limited to) specific battery chargers, instrument transformers, trip coils and/or control circuitry (etc.).

9.1 Minimum Sample Size

Large Sample Size

An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> "… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)
>
> "If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation." (Elementary Statistics - Picturing the World, Larson, Farber, 2003)
>
> "The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005)
>
> "… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968)

Error of Distribution Formula

Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:

B = bound on the error of distribution (allowable error)

z = standard error
π = expected failure rate
n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance-based Program

One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason the following assumptions are made:

B = 5%
z = 1.96 (This equates to a 95% confidence level)
π = 4%

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance-based Program

The number of components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%
z = 1.44 (85% confidence level)
π = 4%

Using the equation above, n=31.8.

Recommendation

Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended~~:~~ (and required within the standard):

Minimum Population Size to use Performance-based Maintenance Program = 60

Minimum Sample Size to evaluate Performance-based Program = 30.

Once the population segment is defined then maintenance must begin within the intervals as outlined for ~~Level 1 monitoring,~~the device described in the Tables (Table ~~1a).~~1-1 through Table 1-5). Time intervals can be lengthened provided the last year's worth of ~~devices~~components tested (or the last 30 units maintained, whichever is more) had fewer than 4% countable events. It is notable that 4% is specifically chosen because an entity with a small population (60 units) would have to adjust its time intervals between maintenance if more than 1 countable event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a ~~mis-operation~~Misoperation.

The minimum number of units that can be tested in any given year is 5% of the population. Note that this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of countable events equals or exceeds 4% of the last year's tested~~ devices~~ components (or the last 30 units maintained, whichever is more) then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the countable events is less than 4%; this must be attained within three years.

This additional time period of three years to restore segment performance to <4% countable events is mandated to keep entities from "gaming the PBM system". It is believed that this requirement provides the economic disincentives to discourage asset owners from arbitrarily pushing the PBM time intervals out to up to 20 years without proper statistical data.

10. Overlapping the Verification of Sections of the Protection System

~~Table~~Tables 1~~ requires ~~-1 through 1-5 require that every protection system ~~element~~component be periodically verified. One approach is to test the entire protection scheme as a unit, from the secondary windings of voltage and current sources to breaker tripping. For practical ongoing verification, sections of the protection system may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification. See Appendix A of this Supplementary Reference for additional discussion on this topic.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a protection system may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time-based maintenance with appropriate maximum verification intervals for categories of equipment as given in the ~~Unmonitored, Partially Monitored, or Fully Monitored Tables~~Tables 1-1 through 1-5;
- Full monitoring as described in ~~header of Table 1c~~Tables 1-1 through 1-5;
- A performance-based maintenance program as described in Section 9 above or Attachment A of the Standard;
- Opportunistic verification using analysis of fault records as described in Section 11

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve fault event records and oscillographic records by data communications after a fault. They analyze the data closely if there has been an apparent ~~Misoperation~~misoperation, as NERC standards require. Some advanced users have commissioned automatic fault record processing systems that gather and archive the data. They search for evidence of component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured digital fault recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on protection systems whose operations are analyzed. Even electromechanical protection systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of faults in the vicinity of the relay that produce relay response records, and the specific data captured.

A typical fault record will verify particular parts of certain protection systems in the vicinity of the fault. For a given protection system installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external fault records that completely verify the protection system.

For example, fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that fault. A relay or DFR record may indicate correct operation of the protection communications channel. Furthermore, other nearby protection systems may verify that they restrain from tripping for a fault just outside their respective zones of protection. The ensemble of internal fault and nearby external fault event data can verify major portions of the protection system, and reset the time clock for the Table 1 testing intervals for the verified components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity in the record and the associated wiring paths are verified. Be careful about using fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple faults close to either side of a setting boundary, setting or calibration could still be incorrect.
If fault record data is used to show that portions or all of a protection system have been verified to meet Table 1 requirements, the owner must retain the fault records used, and the maintenance related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

12. Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to protection system performance.

Monitoring does not check measuring element settings. Analysis of fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them. For background and guidance, see [5].

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple. With legacy relays (non-microprocessor protective relays) it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific requirement to maintain a settings management process there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.

- A relay is upgraded with a new firmware version.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed systems that are described as self-monitoring.

Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored or partially monitored intervals established in Table 1.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of full monitoring, the manufacturers of the microprocessor-based self-monitoring components in the protection system should publish for the user a document or map that shows:

- How all internal elements of the product are monitored for any failure that could impact protection system performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

With this information in hand, the user can document full monitoring for some or all sections by:

- Presenting or referencing the product manufacturer's documents.
- Explaining in a system design document the mapping of how every component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission facilities through which failures are reported within a given time frame to allocate where action can be taken to initiate resolution of the alarm attributed to a maintenance correctable issue, so that failures of monitoring or alarming systems also lead to alarms and action.
- Documenting the plans for verification of any unmonitored ~~elements~~components according to the requirements of Table 1.

14. Notification of Protection System Failures

When a failure occurs in a protection system, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC standard(s). Knowledge of the failure may impact the system operator's decisions on acceptable loading conditions.

This formal reporting of the failure and repair status to the system operator by the protection system owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance but if its battery maintenance program is lacking then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific components. PRC-005-02 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore *manual intervention* to perform certain activities on these type ~~devices~~components may not be needed.

15.1 Protective Relays (Table 1-1)

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted portion of the BES. Devices that sense thermal, vibration, seismic, pressure, gas or any other non-electrical inputs are excluded.

Non-microprocessor based equipment is treated differently than microprocessor based equipment in the following ways, the relays should meet the asset owners' tolerances.

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
    - There is no specific protective relay commissioning test or relay routine test mandated.
    - There is no specific documentation mandated.

15.2 Voltage & Current Sensing Devices (Table 1-3)

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are considered to be a type of voltage and current sensing devices included in this standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these ~~devices~~components. The important thing about these signals is to know that the expected output from these ~~devices~~components actually reaches the protective relay. Therefore, the proof of the proper operation of these ~~devices~~components also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device all the way to the protective relay. The following observations apply.

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.
- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; by calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to verify the circuit meets the asset owner's protection system maintenance program.

- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this therefore tests the CT as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during load conditions, at the input to the relay.
- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the real-time loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay then the verification activity has been satisfied. Thus event reports (and oscillographs) can be used to verify that the voltage and current sensing devices are performing satisfactorily.
- Still another method is to measure total watts and vars around the entire bus; this should add up to zero watts and zero vars thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- ~~Other~~Any other methods that provide documentation that the expected transformer values as applied to the inputs to the protective relays are acceptable.

15.3 ~~DC~~ Control ~~Circuitry~~circuitry associated with protective functions (Table 1-5)

This component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring (or other signal conveyance) from every trip output to every trip coil. It includes any device needed for the correct processing of the needed trip signal to the trip coil of the interrupting device~~. In short, every trip~~; this requirement is meant to capture inputs and outputs to and from a protective relay that are necessary for the correct operation of the protective functions. In short, every trip path must be verified and every I/O path must be verified; the method of verification is optional to the asset owner. An example of testing methods to accomplish this might be to verify, with a volt-meter, the existence of the proper voltage at the open contacts, the open circuited input circuit and at the trip coil(s). As every parallel trip path has similar failure modes, each trip path from relay to trip coil must be verified. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once. There is a requirement to operate the circuit breaker (or other interrupting device) at least once every six years as part of the complete functional test. If a suitable monitoring system is installed that verifies every parallel trip path then the manual-intervention testing of those parallel trip paths can be extended ~~to~~beyond twelve years, however the actual operation of the circuit breaker must still occur at least once every six years. This 6-year tripping requirement can be completed as easily as tracking the real-time fault-clearing operations on the circuit breaker~~.~~ or tracking the trip coil(s) operation(s) during circuit breaker routine maintenance actions

The circuit-interrupting device should not be confused with a motor-operated disconnect. The intent of this standard is to require maintenance intervals and activities on Protection Systems equipment and not just all equipment.

It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device if this ground switch is utilized in a Protection System and forces a ground fault to occur that then results in an expected Protection System operation to clear the forced ground fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is "…applied on, or designed to provide protection for the BES…" then this device needs to be treated as any other Protection System component. The control circuitry would have to be tested within 12 years and any electromechanically operated device will have to be tested every 6 years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit then the solenoid triggering unit can easily be tested without the actual closing of the ground blade.

~~Distribution circuit~~ Circuit breakers that participate in ~~the~~a distributed UFLS or UVLS scheme are excluded from the ~~trip-testing~~tripping requirement, but not from the circuit test requirements; since the circuitry must be tested at least once every 12 years and the circuit interrupting device need not be tested then this effectively makes this a 12 year requirement. There are many circuit interrupting devices in the distribution system that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping-action of a single ~~distribution~~distributed system circuit breaker will be far less significant than, for example, any single Transmission Protection System failure such as a failure of a Bus Differential Lock-Out Relay. While many failures of these ~~distribution~~distributed system circuit breakers could add up to be significant, it is also believed that ~~distribution~~many circuit breakers are operated often on just fault clearing duty and therefore ~~the distribution~~these circuit breakers are operated at least as frequently as any requirements that ~~might have appeared~~appear in this standard.

The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) that may exist in any ~~given~~particular trip scheme. ~~These~~ If these devices are electro-mechanical ~~devices~~components then they must be trip tested. The PSMT SDT considers these ~~devices~~components to share some similarities in failure modes as electro-mechanical protective relays; as such there is a six year maximum interval between mandated maintenance tasks unless PBM is applied.

When verifying the operation of the 94 and 86 relays each normally-open contact that closes to pass a trip signal must be verified as operating correctly. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.

New technology is also accommodated here; there are some tripping systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment.

15.4 Batteries and DC Supplies (Table 1-4)

IEEE guidelines were consulted to arrive at the maintenance activities for batteries. The following guidelines were used: IEEE 450 (for Vented Lead-Acid batteries), IEEE 1188 (for Valve-Regulated Lead-Acid batteries) and IEEE 1106 (for Nickel-Cadmium batteries).

The ~~present~~currently proposed NERC definition of a Protection System is ~~"*protective*~~

- Protective relays~~, *associated communication*~~ which respond to electrical quantities,
- communications systems~~,~~ necessary for correct operation of protective functions,
- voltage and current sensing devices~~,~~ providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and ~~*dc*~~ non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices." The station battery is not the only component that provides dc power to a Protection System. In the new definition for Protection System "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. An open battery string will be an unavailable power source in the event of loss of the battery charger.

Batteries cannot be a unique population segment of a Performance-based Maintenance Program (PBM) because there are too many variables in the electro-chemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery systems. However, nothing precludes the use of a PBM process for any other part of a dc supply besides the batteries themselves.

15.5 ~~Tele-protection~~Associated communications equipment (Table 1-2)

~~This is also known as associated telecommunications equipment.~~ The equipment used for tripping in a communications assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested.

Besides the trip output and wiring to the trip coil(s) there is also a communications medium that must be maintained.

Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology.

For example: older technologies may have included *Frequency Shift Key* methods. This technology requires that guard and trip levels be maintained.

The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests.

Emerging technologies transfer digital information over a variety of carrier mediums that are then interpreted locally as trip signals.

The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore this standard is applied to equipment used to convey both trip signals (permissive or direct) and block signals.

It was the intent of this standard to require that a test be made of any communications-assisted trip scheme regardless of the vintage of the technology. The essential element is that the tripping (or blocking) occurs locally when the remote action has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted.

~~Evidence~~Any evidence of operational test or documentation of measurement of signal level, reflected power or data-error rates ~~is needed~~can fulfill the requirements.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

15.6 Alarms (Table 2)

In addition to the tables of maintenance for the components of a Protection System, there is an additional table added for alarms. This additional table was added for clarity. This enabled the common alarm attributes to be consolidated into a single spot and thus make it easier to read the Tables 1-1 through 1-5. The alarms need to arrive at a site wherein a corrective action can be initiated. This could be a control room, operations center, etc. The alarming mechanism can be a standard alarming system or an auto-polling system, the only requirement is that the alarm be brought to the action-site within 24 hours. This effectively makes manned-stations equivalent to monitored stations. The alarm of a monitored point (for example a monitored trip path with a lamp) in a manned-station now makes that monitored point eligible for monitored status. Obviously, these same rules apply to a non-manned-station, which is that if the monitored point has an alarm that is auto-reported to the operations center (for example) within 24 hours then it too is considered monitored.

15.7 Examples of Evidence of Compliance

To comply with the requirements of this Standard an entity will have to document and save evidence. The evidence can be of many different forms. The Standard Drafting Team recognizes that there are concurrent evidence requirements of other standards that could, at times fulfill evidence requirements of this standard.

For example: maintaining evidence for operation of Special Protection Systems could concurrently be utilized as proof of the operation of the associated trip coil (provided one can be certain of the trip coil involved). Thus the reporting requirements that one may have to do for the ~~misoperation~~mis-operation of a Special Protection Scheme under PRC-016 could work for the activity tracking requirements under this PRC-005-2.

Another example might be:

Some entities maintain records of all interruptions. These records can be concurrently utilized, if the entity desires, as DC Trip Path verifications.

Analysis of Event Recordings can provide details that can eliminate some hands-on maintenance activities; ~~however,~~ merely printing out the event report provides limited benefit of verification of specific maintenance items.

Standardized-forms, hard or soft copy, can be created, filled out and archived. These forms can be of the entities' design and can be aimed at answering the specific requirements of the Standard as well as additional requirements as needed by the entity.

Fill-in blanks, check-boxes, drop-down lists, auto-date formats, etc. can all be used as the primary action is the maintenance activity~~; the secondary action is~~ time interval; other techniques can be used to verify that the maintenance activity was performed, such as test reports.

Other evidence of compliance might be, but is not limited to:

Prints, maintenance plans, training materials, policies, procedures, data print-outs or exhibits, correspondence, reports, data-base records, etc.

There is the legacy method of paper trail for everything, this is acceptable. There are also paperless systems existing and evolving that are also acceptable.

Proof of compliance should simply be the entities' records of maintenance completed.

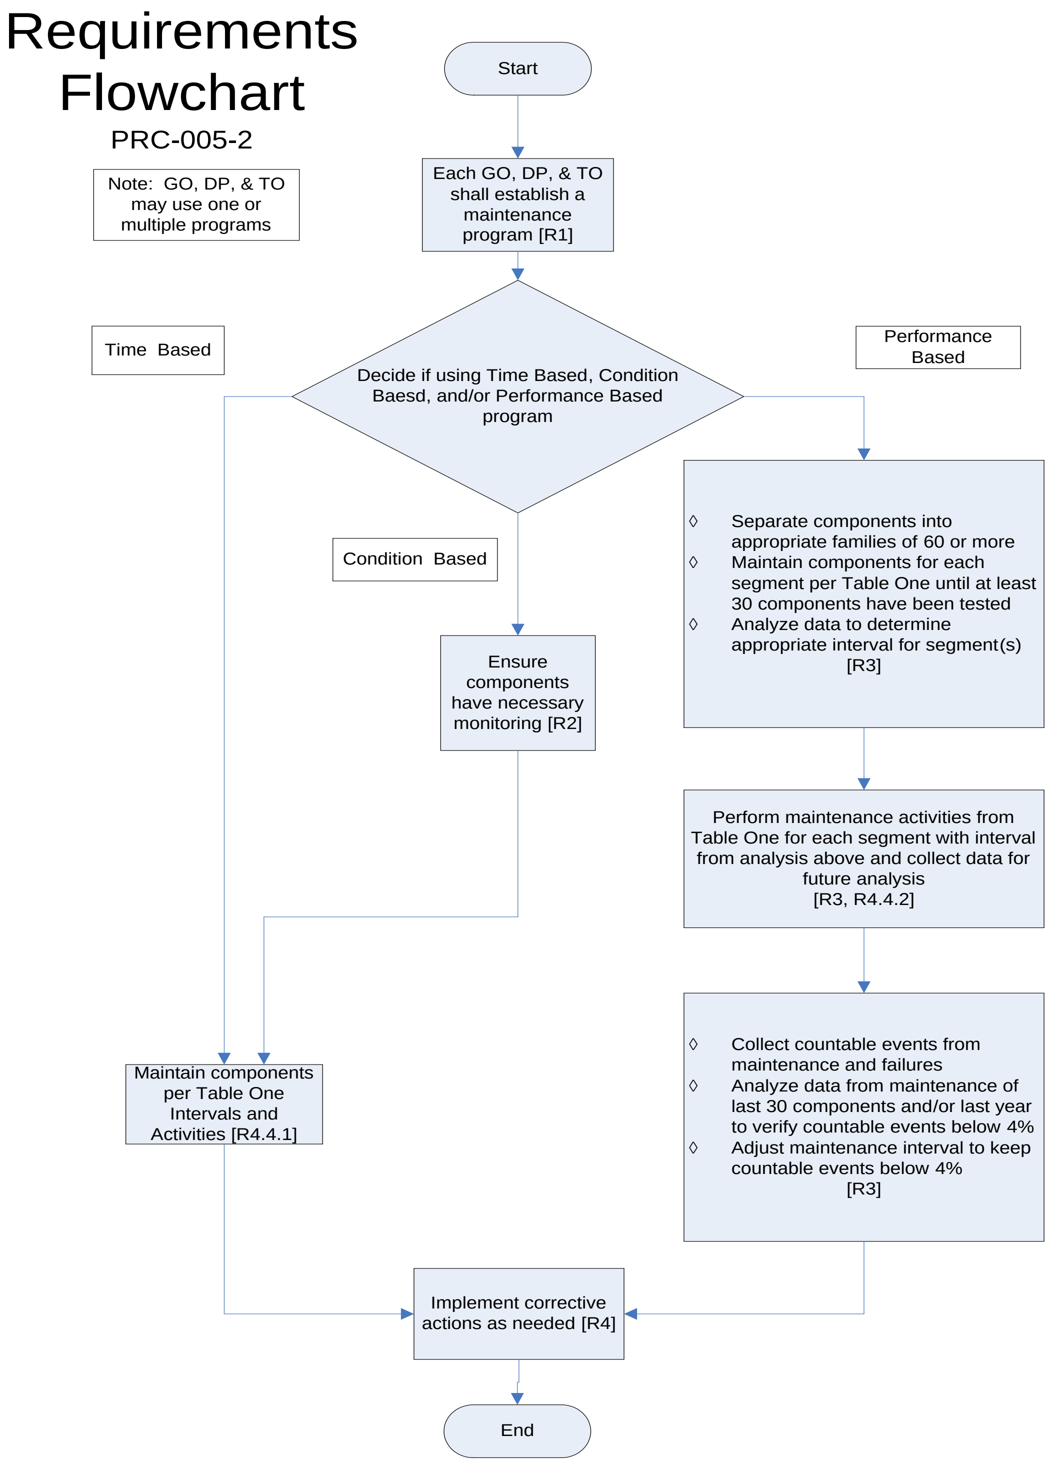
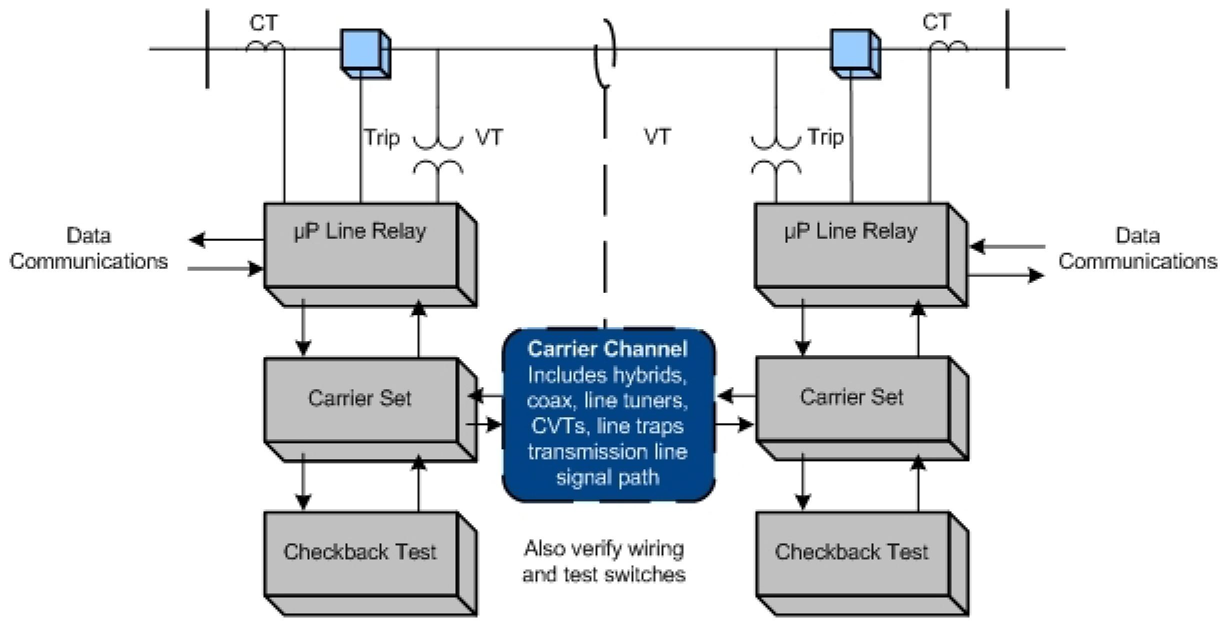
Figure 3: Requirements Flowchart



Appendix A

The following illustrates the concept of overlapping verifications and tests as summarized in Section 10 of the paper. As an example, Figure A-1 shows protection for a critical transmission line by carrier blocking directional comparison pilot relaying. The goal is to verify the ability of the entire two-terminal pilot protection scheme to protect for line faults, and to avoid over-tripping for faults external to the transmission line zone of protection bounded by the current transformer locations.

Figure A-1



In this example (Figure A1), verification takes advantage of the self-monitoring features of microprocessor multifunction line relays at each end of the line. For each of the line relays themselves, the example assumes that the user has the following arrangements in place:

1. The relay has a data communications port that can be accessed from remote locations.
2. The relay has internal self-monitoring programs and functions that report failures of internal electronics, via communications messages or alarm contacts to SCADA.
3. The relays report loss of dc power, and the relays themselves or external monitors report the state of the dc battery supply.
4. The CT and PT inputs to the relays are used for continuous calculation of metered values of volts, amperes, plus Watts and VARs on the line. These metered values are reported by data communications. For maintenance, the user elects to compare these readings to those of other relays, meters, or DFRs. The other readings may be from redundant relaying or measurement systems or they may be derived from values in other protection zones. Comparison with other such readings to within required relaying accuracy verifies Voltage & Current Sensing

Devices, wiring, and analog signal input processing of the relays. One effective way to do this is to utilize the relay metered values directly in SCADA, where they can be compared with other references or state estimator values.

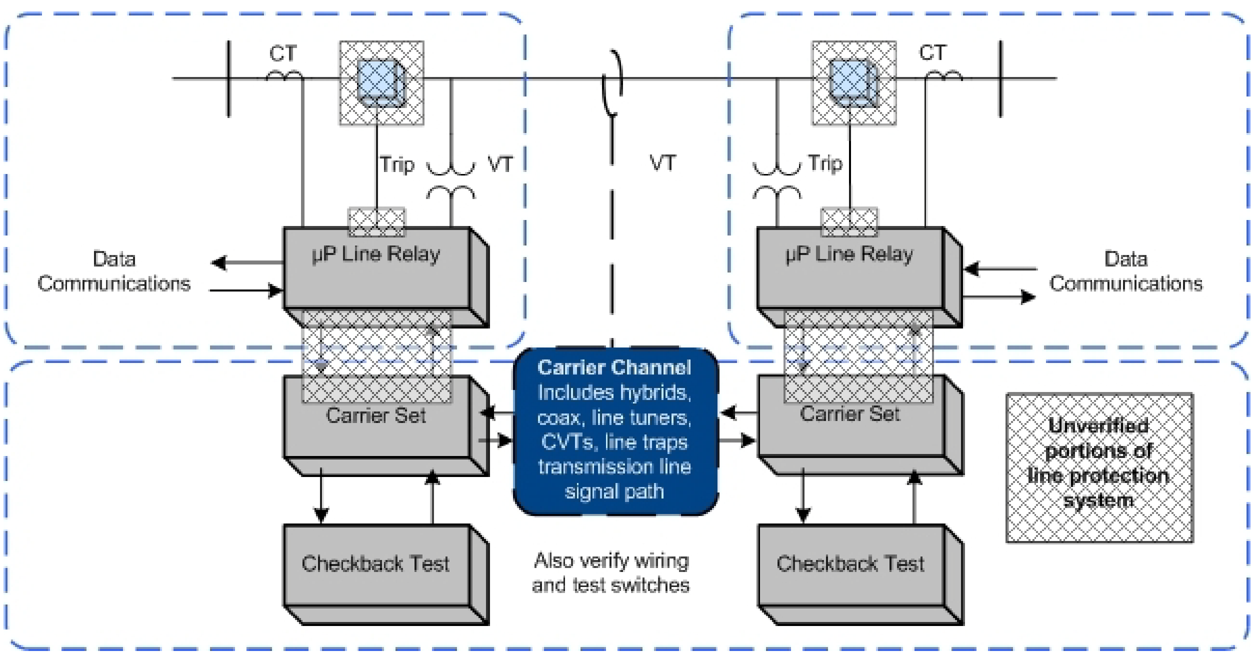
5. Breaker status indication from auxiliary contacts is verified in the same way as in (2). Status indications must be consistent with the flow or absence of current.

6. Continuity of the breaker trip circuit from dc bus through the trip coil is monitored by the relay and reported via communications.

7. Correct operation of the on-off carrier channel is also critical to security of the protection system, so each carrier set has a connected or integrated automatic checkback test unit. The automatic checkback test runs several times a day. Newer carrier sets with integrated checkback testing check for received signal level and report abnormal channel attenuation or noise, even if the problem is not severe enough to completely disable the channel.

These monitoring activities plus the check-back test comprise automatic verification of all the protection system elements that experience tells us are the most prone to fail. But, does this comprise a complete verification?

Figure A-2



The dotted boxes of Figure A-2 show the sections of verification defined by the monitoring and verification practices just listed. These sections are not completely overlapping, and the shaded regions show elements that are not verified:

1. The continuity of trip coils is verified, but no means is provided for validating the ability of the circuit breaker to trip if the trip coil should be energized.

2. Within each line relay, all the microprocessors that participate in the trip decision have been verified by internal monitoring. However, the trip circuit is actually energized by the contacts of a small telephone-type "ice cube" relay within the line protective relay. The microprocessor energizes the coil of this ice cube relay through its output data port and a transistor driver circuit. There is no monitoring of the output port, driver circuit, ice cube relay, or contacts of that relay. These components are critical for tripping the circuit breaker for a fault.
3. The check-back test of the carrier channel does not verify the connections between the relaying microprocessor internal decision programs and the carrier transmitter keying circuit or the carrier receiver output state. These connections include microprocessor I/O ports, electronic driver circuits, wiring, and sometimes telephone-type auxiliary relays.
4. The correct states of breaker and disconnect switch auxiliary contacts are monitored, but this does not confirm that the state change indication is correct when the breaker or switch opens.

A practical solution for (1) and (2) is to observe actual breaker tripping, with a specified maximum time interval between trip tests. Clearing of naturally-occurring faults are demonstrations of operation that reset the time interval clock for testing of each breaker tripped in this way. If faults do not occur, manual tripping of the breaker through the relay trip output via data communications to the relay microprocessor meets the requirement for periodic testing.

PRC-005 does not address breaker maintenance, and its protection system test requirements can be met by energizing the trip circuit in a test mode (breaker disconnected) through the relay microprocessor. This can be done via a front-panel button command to the relay logic, or application of a simulated fault with a relay test set. However, utilities have found that breakers often show problems during protection system tests. It is recommended that protection system verification include periodic testing of the actual tripping of connected circuit breakers.

Testing of the relay-carrier set interface in (3) requires that each relay key its transmitter, and that the other relay demonstrate reception of that blocking carrier. This can be observed from relay or DFR records during naturally occurring faults, or by a manual test. If the checkback test sequence were incorporated in the relay logic, the carrier sets and carrier channel are then included in the overlapping segments monitored by the two relays, and the monitoring gap is completely eliminated.

A. Introduction

1. **Title:** **Transmission and Generation Protection System Maintenance and Testing**

2. **Number:** PRC-005-1

3. **Purpose:** To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.

4. **Applicability**

   4.1. Transmission Owner.

   4.2. Generator Owner.

   4.3. Distribution Provider that owns a transmission Protection System.

5. **Effective Date:** May 1, 2006

B. Requirements

R1. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall have a Protection System maintenance and testing program for Protection Systems that affect the reliability of the BES. The program shall include:

R1.1. Maintenance and testing intervals and their basis.

R1.2. Summary of maintenance and testing procedures.

R2. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall provide documentation of its Protection System maintenance and testing program and the implementation of that program to its Regional Reliability Organization on request (within 30 calendar days). The documentation of the program implementation shall include:

R2.1. Evidence Protection System devices were maintained and tested within the defined intervals.

R2.2. Date each Protection System device was last tested/maintained.

C. Measures

M1. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System that affects the reliability of the BES, shall have an associated Protection System maintenance and testing program as defined in Requirement 1.

M2. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System that affects the reliability of the BES, shall have evidence it provided documentation of its associated Protection System maintenance and testing program and the implementation of its program as defined in Requirement 2.

D. Compliance

1. **Compliance Monitoring Process**

   1.1. Compliance Monitoring Responsibility

   Regional Reliability Organization.

1.2. Compliance Monitoring Period and Reset Time Frame

One calendar year.

1.3. Data Retention

The Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System, shall retain evidence of the implementation of its Protection System maintenance and testing program for three years.

The Compliance Monitor shall retain any audit data for three years.

1.4. Additional Compliance Information

The Transmission Owner and any Distribution Provider that owns a transmission Protection System and the Generator Owner that owns a generation Protection System, shall each demonstrate compliance through self-certification or audit (periodic, as part of targeted monitoring or initiated by complaint or event), as determined by the Compliance Monitor.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program provided was incomplete as required in R1, but records indicate maintenance and testing did occur within the identified intervals for the portions of the program that were documented.

2.2. Level 2: Documentation of the maintenance and testing program provided was complete as required in R1, but records indicate that maintenance and testing did not occur within the defined intervals.

2.3. Level 3: Documentation of the maintenance and testing program provided was incomplete, and records indicate implementation of the documented portions of the maintenance and testing program did not occur within the identified intervals.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation, was not provided.

E. Regional Differences

None identified.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New
1	December 1, 2005	1. Changed incorrect use of certain hyphens (-) to “en dash” (–) and “em dash (—).” 2. Added “periods” to items where appropriate. 3. Changed “Timeframe” to “Time Frame” in item D, 1.2.	01/20/05

A. Introduction

1. Title: **Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program**

2. Number: PRC-008-0

3. Purpose: Provide last resort system preservation measures by implementing an Under Frequency Load Shedding (UFLS) program.

4. Applicability:

4.1. Transmission Owner required by its Regional Reliability Organization to have a UFLS program

4.2. Distribution Provider required by its Regional Reliability Organization to have a UFLS program

5. Effective Date: April 1, 2005

B. Requirements

R1. The Transmission Owner and Distribution Provider with a UFLS program (as required by its Regional Reliability Organization) shall have a UFLS equipment maintenance and testing program in place. This UFLS equipment maintenance and testing program shall include UFLS equipment identification, the schedule for UFLS equipment testing, and the schedule for UFLS equipment maintenance.

R2. The Transmission Owner and Distribution Provider with a UFLS program (as required by its Regional Reliability Organization) shall implement its UFLS equipment maintenance and testing program and shall provide UFLS maintenance and testing program results to its Regional Reliability Organization and NERC on request (within 30 calendar days).

C. Measures

M1. Each Transmission Owner's and Distribution Provider's UFLS equipment maintenance and testing program contains the elements specified in Reliability Standard PRC-007-0_R1.

M2. Each Transmission Owner and Distribution Provider shall have evidence that it provided the results of its UFLS equipment maintenance and testing program's implementation to its Regional Reliability Organization and NERC on request (within 30 calendar days).

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Compliance Monitor: Regional Reliability Organization.

1.2. Compliance Monitoring Period and Reset Timeframe

On request (within 30 calendar days).

1.3. Data Retention

None specified.

1.4. Additional Compliance Information

None.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.2. Level 2: Complete documentation of the maintenance and testing program was provided, but records indicate that implementation was not on schedule.

2.3. Level 3: Documentation of the maintenance and testing program was incomplete, and records indicate implementation was not on schedule.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation was not provided.

E. Regional Differences

1. None identified.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New

A. Introduction

1. **Title:** **Undervoltage Load Shedding System Maintenance and Testing**

2. **Number:** PRC-011-0

3. **Purpose:** Provide system preservation measures in an attempt to prevent system voltage collapse or voltage instability by implementing an Undervoltage Load Shedding (UVLS) program.

4. **Applicability:**

   4.1. Transmission Owner that owns a UVLS system

   4.2. Distribution Provider that owns a UVLS system

5. **Effective Date:** April 1, 2005

B. Requirements

R1. The Transmission Owner and Distribution Provider that owns a UVLS system shall have a UVLS equipment maintenance and testing program in place. This program shall include:

R1.1. The UVLS system identification which shall include but is not limited to:

R1.1.1. Relays.

R1.1.2. Instrument transformers.

R1.1.3. Communications systems, where appropriate.

R1.1.4. Batteries.

R1.2. Documentation of maintenance and testing intervals and their basis.

R1.3. Summary of testing procedure.

R1.4. Schedule for system testing.

R1.5. Schedule for system maintenance.

R1.6. Date last tested/maintained.

R2. The Transmission Owner and Distribution Provider that owns a UVLS system shall provide documentation of its UVLS equipment maintenance and testing program and the implementation of that UVLS equipment maintenance and testing program to its Regional Reliability Organization and NERC on request (within 30 calendar days).

C. Measures

M1. Each Transmission Owner and Distribution Provider that owns a UVLS system shall have documentation that its UVLS equipment maintenance and testing program conforms with Reliability Standard PRC-011-0_R1.

M2. Each Transmission Owner and Distribution Provider that owns a UVLS system shall have evidence it provided documentation of its UVLS equipment maintenance and testing program and the implementation of that UVLS equipment maintenance and testing program as specified in Reliability Standard PRC-011-0_R2.

D. Compliance

1. **Compliance Monitoring Process**

1.1. Compliance Monitoring Responsibility

Compliance Monitor: Regional Reliability Organization.

1.2. Compliance Monitoring Period and Reset Timeframe

On request (30 calendar days).

1.3. Data Retention

None specified.

1.4. Additional Compliance Information

None.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.2. Level 2: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.3. Level 3: Documentation of the maintenance and testing program was incomplete, and records indicate implementation was not on schedule.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation, was not provided.

E. Regional Differences

1. None identified.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New

A. Introduction

1. **Title:** **Special Protection System Maintenance and Testing**

2. **Number:** PRC-017-0

3. **Purpose:** To ensure that all Special Protection Systems (SPS) are properly designed, meet performance requirements, and are coordinated with other protection systems. To ensure that maintenance and testing programs are developed and misoperations are analyzed and corrected.

4. **Applicability:**

   4.1. Transmission Owner that owns an SPS

   4.2. Generator Owner that owns an SPS

   4.3. Distribution Provider that owns an SPS

5. **Effective Date:** April 1, 2005

B. Requirements

R1. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall have a system maintenance and testing program(s) in place. The program(s) shall include:

R1.1. SPS identification shall include but is not limited to:

R1.1.1. Relays.

R1.1.2. Instrument transformers.

R1.1.3. Communications systems, where appropriate.

R1.1.4. Batteries.

R1.2. Documentation of maintenance and testing intervals and their basis.

R1.3. Summary of testing procedure.

R1.4. Schedule for system testing.

R1.5. Schedule for system maintenance.

R1.6. Date last tested/maintained.

R2. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall provide documentation of the program and its implementation to the appropriate Regional Reliability Organizations and NERC on request (within 30 calendar days).

C. Measures

M1. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall have a system maintenance and testing program(s) in place that includes all items in Reliability Standard PRC-017-0_R1.

M2. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall have evidence it provided documentation of the program and its implementation to the appropriate Regional Reliability Organizations and NERC on request (within 30 calendar days).

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Compliance Monitor: Regional Reliability Organization. Each Region shall report compliance and violations to NERC via the NERC Compliance Reporting process.

Timeframe:
On request (30 calendar days.)

1.2. Compliance Monitoring Period and Reset Timeframe

Compliance Monitor: Regional Reliability Organization.

1.3. Data Retention

None specified.

1.4. Additional Compliance Information

None.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.2. Level 2: Complete documentation of the maintenance and testing program was provided, but records indicate that implementation was not on schedule.

2.3. Level 3: Documentation of the maintenance and testing program was incomplete, and records indicate implementation was not on schedule.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation, was not provided.

E. Regional Differences

Standards Announcement

Existing Ballot Window Re-opened

Now available at: https://standards.nerc.net/CurrentBallots.aspx

Project 2007-17: Protection System Maintenance and Testing

A successive ballot for the proposed standard, PRC-005-2 — Protection System Maintenance, and a concurrent, non-binding poll on revised VRFs and VSLs are being reopened until a quorum is reached.

Instructions

For those members who have not cast a ballot during this voting window, your vote is needed to achieve quorum since the votes and comments from the last ballot will not be carried over. In addition, members of the ballot pool will need to cast a new opinion on the revised VRFs and VSLs. The drafting team will consider all comments (those submitted with a comment form, and those submitted with a ballot or with the non-binding poll) and will determine whether to make additional changes to the standard and its implementation plan.

During the successive ballot window, members of the ballot pool associated with this project may log in and submit their votes from the following page: https://standards.nerc.net/CurrentBallots.aspx

Documents for this project, including an off-line unofficial copy of the questions listed in the comment forms are posted at the following site:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Note that PRC-005-2 reflects the merging of the following standards into a single standard, making it impractical to post a "redline" of proposed PRC-005-2 that shows the changes to the last balloted version of the standard.

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The last approved versions of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 have been posted on the project's Web page for easy reference at:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Next Steps

The drafting team will consider all comments (those submitted with a comment form, and those submitted with a ballot or with the non-binding poll) and will determine whether to make additional changes to the standard and its implementation plan.

Project Background

The proposed PRC-005-2 – Protection System Maintenance standard addresses FERC directives from FERC Order 693, as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices. For a performance-based maintenance program, it ascertains where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

Applicability of Standards in Project

Transmission Owners
Generator Owners
Distribution Providers

Standards Development Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance, please contact Monica Benson,
Standards Process Administrator, at monica.benson@nerc.net or at 609.452.8060.

Standards Announcement

Successive Ballot Window Open
December 10 – December 19, 2010

Now available at: https://standards.nerc.net/CurrentBallots.aspx

Project 2007-17: Protection System Maintenance and Testing

A successive ballot for the proposed standard, PRC-005-2 — Protection System Maintenance, and a concurrent, non-binding poll on revised VRFs and VSLs are being conducted through **8:00 pm Eastern on Sunday, December 19**.

Instructions

All members of the ballot pool must cast a new ballot since the votes and comments from the last ballot will not be carried over. In addition, members of the ballot pool will need to cast a new opinion on the revised VRFs and VSLs. The drafting team will consider all comments (those submitted with a comment form, and those submitted with a ballot or with the non-binding poll) and will determine whether to make additional changes to the standard and its implementation plan.

During the successive ballot window, members of the ballot pool associated with this project may log in and submit their votes from the following page: https://standards.nerc.net/CurrentBallots.aspx

Documents for this project, including an off-line unofficial copy of the questions listed in the comment forms are posted at the following site:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Note that PRC-005-2 reflects the merging of the following standards into a single standard, making it impractical to post a "redline" of proposed PRC-005-2 that shows the changes to the last balloted version of the standard.

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The last approved versions of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 have been posted on the project's Web page for easy reference at:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Next Steps – Successive Ballot and New, Non-binding Poll of VRFs and VSLs

The drafting team will consider all comments (those submitted with a comment form, and those submitted with a ballot or with the non-binding poll) and will determine whether to make additional changes to the standard and its implementation plan.

Project Background

The proposed PRC-005-2 – Protection System Maintenance standard addresses FERC directives from FERC Order 693, as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices. For a performance-based maintenance program, it ascertains where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

Applicability of Standards in Project

Transmission Owners
Generator Owners
Distribution Providers

Standards Development Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. For more information or assistance, please contact Monica Benson at monica.benson@nerc.net.

For more information or assistance, please contact Monica Benson,
Standards Process Administrator, at monica.benson@nerc.net or at 609.452.8060.

Standards Announcement

Successive Formal Comment Period Open
November 17-December 17, 2010

Now available at: http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Project 2007-17: Protection System Maintenance and Testing

A 30-day formal comment period for the proposed standard, PRC-005-2 — Protection System Maintenance, and its associated implementation plan and reference documents is now open **until 8 p.m. Eastern on December17, 2010**.

Instructions

Please use this electronic form to submit comments on PRC-005-2 and its associated implementation plan and reference documents. If you experience any difficulties in using the electronic form, please contact Monica Benson at Monica.Benson@nerc.net.

Documents for this project, including an off-line unofficial copy of the questions listed in the comment forms are posted at the following site:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Note that PRC-005-2 reflects the merging of the following standards into a single standard, making it impractical to post a "redline" of proposed PRC-005-2 that shows the changes to the last balloted version of the standard.

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The last approved versions of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 have been posted on the project's web page for easy reference at:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Next Steps – Successive Ballot and New, Non-binding Poll of VRFs and VSLs

During the last 10 days of the 30-day formal comment period, a successive ballot will be conducted for 10 days. All members of the ballot pool must cast a new ballot since the votes and comments from the last ballot will not be carried over. In addition, members of the ballot pool will need to cast a new opinion on the revised VRFs and VSLs. The drafting team will consider all comments (those submitted with a comment form, and those submitted with a ballot or with the non-binding poll) and will determine whether to make additional changes to the standard and its implementation plan.

Standards Announcement
Successive Ballot Results
Project 2007-17 – Protection System Maintenance and Testing

Now available at: https://standards.nerc.net/Ballots.aspx

Successive Ballot and Non-binding Poll Results for PRC-005-2 – Protection System Maintenance
A successive ballot for the proposed standard, PRC-005-2 — Protection System Maintenance, ended on December 20, 2010. A non-binding poll of the proposed Violation Risk Factors (VRFs) and Violation Severity Levels (VSLs) also ended on December 20, 2010. Voting and poll statistics are listed below, and the Ballot Results Web page provides a link to the detailed results.

Ballot for Standard:
- Quorum: 79.88 %
- Approval: 44.65%

Non-binding Poll for VRFs and VSLs:
- Quorum: 78.06 %
- Supportive Opinion: 52.73%

Next Steps – Successive Ballot and Non-binding Poll of VRFs and VSLs
The drafting team will consider all comments (those submitted with a comment form, and those submitted with a ballot or with the non-binding poll) and will determine whether to make additional changes to the standard and its implementation plan.

Project Background
The proposed PRC-005-2 – Protection System Maintenance standard addresses FERC directives from FERC Order 693, as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices. For a performance-based maintenance program, it ascertains where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

More information can be found on the project page:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Ballot Criteria
Approval requires both (1) a quorum, which is established by at least 75% of the members of the ballot pool submitting either an affirmative vote, a negative vote, or an abstention, and (2) a two-thirds majority of the

weighted segment votes cast must be affirmative; the number of votes cast is the sum of affirmative and negative votes, excluding abstentions and non-responses.

Non-Binding Polls

Non-binding polls of VRFs and VSLs are conducted to provide the drafting team with constructive feedback on proposed VRFs and VSLs and also to provide information to assist in developing a recommendation for Board of Trustees approval.

Standards Development Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. For more information or assistance, please contact Monica Benson at monica.benson@nerc.net.

Non-binding Poll Results	
Non-binding Poll Name:	Project 2007-17 Protection System Maintenance - Non-binding Poll for VRFs and VSLs_nb2 _in
Poll Period:	12/10/2010 - 12/20/2010
Total # Opinions:	274
Total Ballot Pool:	351
Summary:	78% of those who registered to participate provided an opinion; 53% of those who provided an opinion indicated support for the VRFs and VSLs that were proposed.

What "specific statistical data" was used to validate that unmonitored communication systems are 24 times more prone to failure than unmonitored protective relays? Comments were previously submitted that the 3 month interval for verifying unmonitored communication systems was much too short. The SDT declined to change the interval and in their response stated: "The 3 month intervals are for unmonitored equipment and are based on experience of the relaying industry represented by the SDT, the SPCTF and review of IEEE PSRC work. Relay communications using power line carrier or leased audio tone circuits are prone to channel failures and are proven to be less reliable than protective relays." The 3 month interval is very burdensome and our experience does not appear to justify. A longer interval should be reconsidered.

WECC does not use the definition of the BES that NERC supplied to FERC via http://www.nerc.com/docs/docs/ferc/RM06-16-6-14-07CompFilingPar77ofOrder693FINAL.pdf, so the answer to III.1.3 (page 19-20) is not accurate.

There is no allowance for deferral of maintenance because of factors beyond the control of the TO, GO, or DP. These include the unavailability of customer outages, generation outages, system configuration, high risk of loss of generation or customer load or impact to power quality. Proposed Change: Provide a process for acceptable deferral of maintenance activities. Table 1-4 Table 1-4 The requirement to perform cell internal ohmic resistance measurements every 18 months for vented lead-acid batteries is excessive. Our normal battery life is 20+ years. A 3-year internal resistance test frequency is adequate to prove battery integrity. IEEE 1188 recommends verification of internal ohmic resistance to be on a quarterly bases. It appears other intervals take into account recommended inspection interval plus some grace period. Proposed Change: Change maintenance interval from 3 months to 6 months. Section: R1.5 This new requirement will require significant documentation with no known improvement to the reliability of the BES. What data is being used to determine the need for this requirement? How far does this requirement go? Table 1-4 requires the inspection of “physical condition of battery rack” What are “identify calibration tolerance or other equivalent parameters” for this task? You already have verify, test, inspect, and calibrate defined. Leave out R1.5 which requires more than meeting the definitions.
No
No
Yes
R4 - “Identification of the resolution” and “Initiation of the resolution” are very distinct activities. In other places in this standard the requirement is for the resolution to be initiated, that is identified in a corrective maintenance work order, “identification of a resolution” requires technical expertise and can be difficult to track and might change over time for a particular problem. Proposed Change: Change “identification” to “initiation” in phrase “including identification of the resolution…”. Overall: NERC is making significant changes to this sizeable standard and only allowing minimum comment period. While this is a good standard that has clearly taken many hours to develop, we are primarily voting “NO” because of the hurried fashion it is being commented, voted, and reviewed.

The SDT has greatly improved the clarity of this document in the areas of relays, communication systems, voltage and current sensing devices, control circuitry, and alarming paths. The recommendations on station dc supply are still confusing. First, there are five different attribute categories for unmonitored dc supply. Are these five categories mutually exclusive? Are we supposed to follow just the category applicable to the type of battery? Are we supposed to follow the first category and any of the subsequent four battery type categories as they apply? I suspect some of the 3 month and 18 month items in the first category are considered to be necessary by the SDT regardless of battery type. The current categorization is confusing. If we are required to perform the 3 month and 18 month activities listed in the first category regardless of battery type AS WELL AS the other applicable battery type activities, please indicate this in Table 1-4. As a different option, just eliminate the first category entirely and place the appropriate 3 month and 18 month verification and inspection requirements in the four battery type specific categories. It may be repetitive but clarity is paramount in this standard. Second, the FAQ examples seem to indicate that the SDT views the performance of an internal ohmic battery test or a battery performance test as valid forms for verifying the individual battery cell states (i.e. state of charge of the individual battery cells/units, battery continuity, battery terminal connection resistance, and battery internal cell-to-cell or unit-to-unit connection resistance). It would be helpful if this were more obviously stated in table 1-4.

Currently it could be interpreted that we need to do all of the individual cell-cell verification in addition to the ohm test or the full performance test. I don’t believe this is the intent of the SDT (based on the FAQ examples) but we need to see the intent in Table 1-4. Third, does a monitored dc supply have to monitor some or all of each of the different line items listed? The FAQ examples indicate that if only some are monitored, the dc supply can still be treated as monitored as long as the unmonitored items are verified. This means that for a VLA battery with a low voltage alarm and unintentional ground alarm, all that is needed is to check electrolyte level every 3 months, check float voltage and battery rack every 18 months and perform either an internal ohm check at 18 months or a battery performance test at 6 years. Also battery alarms need to be verified at 6 years. This is not clear in Table 1-4 and it could be interpreted by some that a monitored station dc supply monitors ALL of the listed items not just SOME. The FAQs imply that partial monitoring is acceptable but Table 1-4 does not indicate this very clearly. I do wish to say once again that this proposed standard is much easier to understand and that with a little more clarification in the dc supply section I would vote in the affirmative.

Provide answers to the following questions. Does the completion of a battery ohm test or a battery performance test satisfy the verification requirements for state of charge of the individual battery cells/units, battery continuity, battery terminal connection resistance, and battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)?

Yes
• Clarify what kind of testing is required on lockout relays/86 devices. Specifically, whether functional testing is adequate or if simple calibration, similar to protective relays, is all that is are required. • Clarify if protective relays that trip equipment (e.g., a condensate pump that would in turn cause a main generator trip) are also included in the scope of this Standard. • Clarify if relays which result in generator run back, but do not trip the generator, are included in the scope of this Standard.
Yes
In response to Exelon’s comments provided to drafts 1 and 2 of PRC-005, the SDT did not explain why a conflict with an existing regulatory requirement is acceptable. The SDT responded that a conflict does not exist and that the removal of grace periods simply is there to comply with FERC Order directive 693. This response does not answer or address dual regulation by the NRC and by the FERC. Specifically, the request has not been adequately considered for an allowance for NRC-licensed generating units to default to existing Operating License Technical Specification Surveillance Requirements if there is a maintenance interval that would force shutting down a unit prematurely or become non-compliant with PRC-005. Therefore, Exelon requests that the SDT communicate with the NRC and with the FERC to ensure a conflict of dual regulation is not imposed on a nuclear generating unit without the necessary evaluation. In addition, although Exelon Nuclear agrees with the SDT that the maximum allowed battery capacity testing intervals of not to exceed 6 calendar years for vented lead acid or NiCad batteries (not to exceed 3 calendar years for VRLA batteries) could be integrated within the plant’s routine 18 month to 2 year interval refueling outage schedule, the SDT has not considered that nuclear refueling outages may be extended past the 18 month to 2 year "normal" periodicity. There are some unique factors related to nuclear generating units that the SDT has not taken into consideration in that these units are typically online continuously between refueling

outages without shutting down for any other required maintenance. Historically, generating units have at times extended planned refueling outage shutdown dates days and even weeks due to requests from transmission operations, fuel issues and electrical demand. Without the grace period exclusion currently allowed by existing maintenance programs, a nuclear plant will be forced to either extend outage duration to include testing on an every other refueling outage (i.e., every four years to ensure compliance for a typical boiling water reactor) or leave the testing on a six year periodicity with the vulnerability of a forced shut down simply to perform maintenance to meet the six year periodicity or a self report of non-compliance. To ensure compliance, the nuclear industry will be forced to schedule battery testing on a four year periodicity to ensure the six year periodicity is met, thus imposing a requirement on nuclear generating units that would not apply to other types of generating units. In addition, Exelon has the following technical comments • Sections 4.2.5.4 and 4.2.5.5 need to clearly state that only protection which affects the BES is within the scope of the PRC-005. • There is not enough clarity in the statement "each protection system component type" for one to stay at the component level vs. dropping to sub-component level. If sub-components reviews are required, the effort becomes unmanageable. Therefore the Standard should identify calibration tolerances or other equivalent parameters. Suggest rewording to "each protection system major component type"
Group
Northeast Power Coordinating Council
Guy Zito
No
The wording "Component Type" is not necessary in each title. Just the equipment category should be listed--what is now shown as "Component Type - Protective Relay", should be Protective Relay. However, Protective Relay is too general a category. Electromechanical relays, solid state relays, and microprocessor based relays should have their own separate tables. So instead of reading Protective Relay in the title, it should read Electromechanical Relays, etc. This will lengthen the standard, but will simplify reading and referring to the tables, and eliminate confusion when looking for information. The "Note" included in the heading is also not necessary. "Attributes" is also not necessary in the column heading, "Component" suffices.
No
Because all the requirements deal with protective system maintenance and testing, violations could directly cause or contribute to bulk electric system instability, etc., the VRFs should all be "High". The Time Horizons should all be "Operations Planning" because of the immediacy of a failure to meet the requirements. For the R1 Lower VSL, include a second part to read: Failed to identify calibration tolerances or other equivalent parameters for one Protection System component type that establish acceptable parameters for the conclusion of maintenance activities. For the R1 Moderate VSL, suggest similar wording as for the Lower VSL but specifying two Protection System component types. For the R1 High VSL, suggest changing the wording of the 3rd part to be similar to the Lower VSL to match the requirement and to cater for more than two Protection System component types. For the R3 Severe VSL, in part 3, replace "less" with fewer.
No
Yes
See response to Question 5 below.
Yes
In general, the standard is overly prescriptive and complex. It should not be necessary for a standard at this level to be as detailed and complex as this standard is. Entities working with manufacturers, and knowledge gained from experience can develop adequate maintenance and testing programs. Why are "Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation)…" not included? The output contacts from these devices are oftentimes connected in tripping or control circuits to isolate problem equipment. Due to the critical nature of the trip coil, it must be maintained more frequently if it is not monitored. Trip coils are also considered in the standard as being part of the control circuitry. Table 1-5 has a row labeled "Unmonitored Control circuitry associated with protective functions", which would include trip coils, has a "Maximum Maintenance Interval" of "12 Calendar Years". Any control circuit could fail

at any time, but an unmonitored control circuit could fail, and remain undetected for years with the times specified in the Table (it might only be 6 years if I understand that as being the trip test interval specified in the table). Regardless, if a breaker is unable to trip because of control circuit failure, then the system must be operated in real time assuming that that breaker will not trip for a fault or an event, and backup facilities would be called upon to operate. Thus, for a line fault with a "stuck" breaker (a breaker unable to trip), instead of one line tripping, you might have many more lines deloaded or tripped because of a bus having to be cleared because of a breaker failure initiation. The bulk electric system would have to be operated to handle this contingency. In reference to the FAQ document, Section 5 on Station dc Supply, Question K, clarification is needed with respect to dc supplies for communication within the substation. For example, if the communication systems were run off a separate battery in separate area in a substation, would the standard apply to these batteries or not? To define terms only as they are used in PRC-005-2 is inviting confusion. Although they may be unique to PRC-005-2, some or all of them may be used in future standards, some already may be used in existing standards, and may or may not be deliberately defined. Consistency must be maintained, not only for administrative purposes, but for effective technical communications as well. What is the definition of "Maintenance" as used in the table column "Maximum Maintenance Interval"? Maintenance can range from cleaning a relay cover to a full calibration of a relay. A control circuit is not a component, it is made up of components. Sub-requirement 1.5 needs to be clarified. It is not clear what "Identify calibration tolerances or other equivalent parameters…" means, and may be subject to different interpretations by entities and compliance enforcement personnel. In the Implementation plan for Requirement R1, recommend changing "six" to fifteen. This change would restore the 3-month time difference that existed in the previous draft, between the durations of the implementation periods for jurisdictions that do and do not require regulatory approval. It will ensure equity for those entities located in jurisdictions that do not require regulatory approval, as is the case in Ontario. The 'box' for "Monitored Station dc supply…" in Table 1-4 is not clear. It seems to continue to the next page to a new box. There are multiple activities without clear delineation. Regarding station service transformers, Item 4.2.5.5 under Applicability should be deleted. The purpose of this standard is to protect the BES by clearing generator, generator bus faults (or other electrical anomalies associated with the generator) from the BES. Having this standard apply to generator station service transformers, that have no direct connection to the BES, does meet this criteria. The FAQs (III.2.A) discuss how the loss of a station service transformer could cause the loss of a generating unit, but this is not the purpose of PRC-005. Using this logic than any system or device in the power plant that could cause a loss of generation should also be included. This is beyond the scope of the NERC standards. The Drafting Team must respond to the following concerns raised in the FERC NOPR, Docket No. RM10-5-000, Interpretation of Protection System Reliability Standard, December 16, 2010) to "prevent a gap in reliability". • Any component that detects any quantity needed to take an action, or that initiates any control action (initial tripping, reclosing, lockout, etc.) affecting the reliability of the Bulk-Power System should be included as a component of a Protection System, as well as any component or device that is designed to detect defective lines or apparatuses or other power system conditions of an abnormal or dangerous nature and to initiate appropriate control circuit actions. • The exclusion of auxiliary relays will result in a gap in the maintenance and testing of Protection Systems affecting the reliability of the Bulk-Power System. • Excluding the maintenance and testing of reclosing relays will result in a gap in the maintenance and testing of relays affecting the reliability of the Bulk-Power System. • Not establishing the specific requirements relative to the scope and/or methods for a maintenance and testing program for the DC control circuitry that is necessary to ensure proper operation of the Protection System, including voltage and continuity.

The maintenance requirements for batteries listed in Table 1-4 do not appear to be consistent with example 1 in Section V, 1A of the FAQ. Specifically the FAQ does not mention the state of charge of the individual battery cells/units, the battery continuity, the battery terminal connection resistance, the battery internal cell-to-cell or unit-to-unit connection resistance, or the cell condition, which are indicated as 18 month interval tasks in table 1-4.
No

The high VSL for R1 “Failed to include all maintenance activities relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5” may be interpreted in different ways and should be further clarified.
No
Yes
As previously stated, the maintenance requirements for batteries listed in Table 1-4 do not appear to be consistent with example 1 in Section V, 1A of the FAQ. Specifically the FAQ does not mention the state of charge of the individual battery cells/units, the battery continuity, the battery terminal connection resistance, the battery internal cell-to-cell or unit-to-unit connection resistance, or the cell condition which are indicated as 18 month interval tasks in table 1-4.
Yes
1) We disagree with the requirements for battery maintenance outlined in table 1-4. In particular the requirement for a 3 month check on electrolyte level seems too frequent based on our experience. We would like to point out that although IEEE std 450 (which seems to be the basis for table 1-4) does recommend intervals it also states that users should evaluate these recommendations against their own operating experience. 2) Also, the Implementation Plan is not consistent for areas requiring regulatory approval and areas requiring regulatory approval. The 6 month time frame proposed for R1 for areas not requiring regulatory approval is not achievable and is not consistent with areas requiring regulatory approval. To be consistent, the effective date for R1 in jurisdictions where no regulatory approval is required should be the first day of the first calendar quarter 12 months after BOT approval.

Yes
No
The 5%, 10%, and 15% levels for R2 & R4 exaggerate the severity levels for small companies. A small DP with only 9 relays in a protection system would only have to be missing 1 record for a severe VSL.
No
No
Yes
Please clarify what is required by R1.5: Identify calibration tolerances or other equivalent parameters for each Protection System component type that establish acceptable parameters for the conclusion of maintenance activities required. Is the intent a brief summary for each component type in the PSMP that would cover all equipment within that component type, or is it a detailed list of each piece of equipment within each component type? The inclusion of dated check-off lists in M4 provides much needed clarity to the list of evidence.

Oncor Electric Delivery Company LLC
Yes
No
Oncor strongly disagrees with the modification to the Violation Severity Levers (VSL) table under the High VSL column where it states that it is a high VSL for “Failed to establish calibration tolerance or equivalent parameters to determine if components are within acceptable parameters.” Oncor feels modifying the standard by adding a requirement that requires a Transmission Owner, Generation Owner or Distribution Provider to “identify calibration tolerances or other equivalent parameters for each Protection System component type that establish acceptable parameters for the conclusion of maintenance activities” is too intrusive and divisive for what it brings to the reliability of the BES. The requirement (Requirement R1 part 1.5) and its associated High VSL should be removed from PRC-005-2.
No
Yes
There is still confusion in Table 1-4 concerning the “Monitored Station dc supply.” The uncertainty is over whither an Owner must have all seven (7) monitoring activities (Station dc supply voltage, State of charge of the individual battery cell/units, Battery continuity of station battery, Cell-to-cell and battery terminal resistance, Electrolyte level of all cells in station battery, Unintentional dc grounds, and Cell/unit internal ohmic values of station battery) listed in the table or just one of them to take advantage of forgoing the maximum maintenance interval for an activity and going to the 6 year maximum maintenance interval to verify that the monitoring device is calibrated. A FAQ concerning this question would be beneficial to those who are concerned that they must monitor all seven activities in order to take advantage of condition based maintenance for the station dc supply. Also an explanation of how each of the 7 monitoring activities relates to a specific station dc supply maintenance activity might be beneficial.
Yes
Comment A: Oncor believes that Requirement R1 Part 1.5 of this Standard should be removed. It is too vague, intrusive, and divisive for what it brings to the reliability of the BES. Specifically it burdens all Transmission Owners, Generation Owners or Distribution Providers with the impossible task of having to “identify calibration tolerances or other equivalent parameters for each Protection System component type that establish acceptable parameters for the conclusion of maintenance activities.” By definition a Protection System component type is “any one of the five specific elements of the Protection System definition” and “a component is any individual discrete piece of equipment included in a Protection System, such as a protective relay or current sensing device.” What Requirement R1 part 1.5 with its associated High VSL in the Standard would decree is that all Transmission Owners, Generation Owners and Distribution Providers who “failed to establish calibration tolerance or equivalent parameters to determine if every individual discrete piece of equipment in a Protection System is within acceptable parameters” would be in violation of the Standard – with a High VSL. Oncor with over 98 years of Protection System maintenance experience feels that most Owners including itself would be non-compliant with this unclear, meddling and disruptive requirement no matter how long the implementation plan for the Standard is. Comment B: Oncor believes that in light of Comment “A” above Requirement R4 Part 4.2 must be modified to remove all references to Requirement R1 Part 1.5 of the Standard. The new requirement should be modified to read “Either verify that the components are within acceptable parameters at the conclusion of the maintenance activities or initiate any necessary activities to correct maintenance correctable issues.” Also in order to assist both the owners and the compliance authorities who may question how one verifies that the

components are within acceptable parameters the FAQ document should be modified to discuss how many utilities are doing this with results that indicate either a pass or fail certified by the qualified persons performing maintenance. Comment C: Oncor feels that the wording “no less frequently than” found in Requirement R4 Parts 4.1.1 and 4.1.2 should be chanced back to the wording in the previous version of the Standard “not to exceed.” Comment D: Oncor recommends that in light of Comment “A” above Measure M1 be modified to remove all reference to Requirement R1 Part 1.5. Comment E: Oncor, as stated in Comment “B” above, recommends that the FAQ document be modified to provide more information on what could be used for evidence that the Transmission Owner, Generation Owner or Distribution Provider has “initiated resolution of identified maintenance correctable issues.” This will assist both the owners and the compliance authorities in answering the question of what constitutes proof that a maintenance correctable issue was identified. Comment F: The second and third paragraphs added under Compliance 1.3 Data Retention provide more information as to what data is required to be retained. Oncor feels that these two paragraphs will help the compliance authorities, the Transmission Owners, Generation Owners and Distribution Providers needed guidance of what is required for data retention.

Yes
The tables clearly tie to each component type in a Protection System. This is consistent with the required PSMP format, making it straight forward to incorporate the intervals and to demonstrate compliance.
Yes
Ingleside Cogeneration, LP, believes that the Section 15.5 of the Supplementary Reference “Associated communications equipment (Table 1-2)” properly reflects the intent of the validation of relay-to-relay communications. It states that any “evidence of operational test or documentation of measurement of signal level, reflected power or data-error rates can fulfill the requirements.” However, Table 1-2 – which will be the ultimate reference used by audit teams – only clearly allows for the measurement of channel parameters. Although the newer technology relays provide read-outs of signal level or data-error rates that do not require intrusive testing, older relays do not. The tools required to perform such testing are not easily available – and may leave the communications channel in worse shape after testing than it was prior to testing. We believe that Table 1-2 should be updated to clearly state that an operational test is sufficient for the testing of relay-to-relay communication – consistent with the Supplementary Reference.
The latest version of PRC-005-2 includes a new requirement (R1.5) to identify calibration tolerances or equivalent parameters that must be verified before a maintenance activity is considered complete. Although we understand the project team’s intent, Ingleside Cogeneration LP is concerned that this requirement will lead to multiple interpretations of which tolerances or parameters are the most important. In addition, audit teams may expect to see certain values based upon their own sense of reliability. This is exactly the ambiguity that PRC-005-2 is trying to eliminate. In addition, calibration tolerances and reliability parameters may vary by equipment manufacturer or by configuration. It is not clear that documenting every scenario to demonstrate regulatory compliance is a benefit to BES reliability.

IMPA does not agree with the percentage in the VSL table for R4. For smaller entities that have six or less of any one type of Protection System Component and they fail, for whatever reason (even if it's a matter of incomplete documentation), to complete scheduled program maintenance on that component they will be subjected to the severe VSL penalty Matrix. Consideration should be given to

entities having less than say, 100 of a component. There should be some type of tiered sub table within the VSL matrix for this consideration - registered entities having a certain component in quantities greater than or equal to 100 and registered entities having quantities of that certain component of less than 100.
No
No
Yes
Standard PRC-005-2 Draft 3 contains a section of "Definitions of Terms Used in Standard" that includes newly defined or revised terms uses in this proposed standard. There are a number of references made to these Terms in the Standard that are not capitalized. IMPA would propose that anywhere that the terms included in the "Definition of Terms Used" are used in the standard that they be capitalized. When any word is not capitalized in a standard then the common practice is to use the Webster Dictionary meaning. IMPA does not know why the SDT is reluctant to put these terms in the NERC Glossary of Terms, but by putting the terms in the glossary it would eliminate any confusion. When these terms are capitalized all registered entities will know that these are defined terms and will be able to consistently apply the definition without confusion. For example: 1.1 Address all Protection System component types. would become 1.1 Address all Protection System Component Types. If these terms are not capitalized in the standard (meaning they are not referring to the defined term) then the meaning of these terms could vary not only from utility to utility but also from Region to Region.

The tables are generally much clearer and the SDT is to be commended on their efforts. However, we believe the Alarming Point Table needs additional clarification with regard to the Maximum Maintenance Interval. If an “alarm producing device” is considered to be a device such as an SCADA RTU, individual entity intervals for such a device would differ, and there isn’t necessarily a maximum interval established as there is for Protection System components. Also, if an entity’s alarm producing device maintenance is performed in sections and triggered by segment or component maintenance, there would essentially be multiple maximum intervals for the alarm producing device of that entity. On that basis, we suggest the interval verbiage be revised to “When alarm producing device or system is verified, or by sections as per the monitored component/protection system specified maximum interval as applicable”. Alternately, if the intention is to establish maximum intervals as simply being no longer than the individual component maintenance intervals as we suggest for inclusion above, then the verbiage should be revised to “When alarm producing component/protection system segment is verified”. In either case are we to interpret monitored components with attributes which allow for no periodic maintenance specified as not requiring periodic alarm verification?
No

R1.5 calls for “identification of calibration tolerances or equivalent parameters…” whereas the associated VSL references “failure to establish calibration criteria….” and is listed as high. If R1.5 is to be included in this standard, then we suggest the severity level of a failure to simply “identify” or document such calibration tolerances would be analogous to the severity level(s) of a “failure to specify one (or Cthe severity level should be consistent with the other elements of R1. Both cases appear to be more of a documentation issue as opposed to a failure to implement. Shouldn’t a failure to implement any necessary calibration tolerance be accounted for in R4?
Yes
R1.5 calls for “identification of calibration tolerances or equivalent parameters for each Protection System Component Type….”. We believe the Supplementary Reference document should provide additional information and examples of calibration tolerances or equivalent parameters which would be expected for the various component types. Especially for any “equivalent” parameters which would be required for compliance for a component type besides protective relays.
Yes
Section II.2.B references R4.3 which has been revised to R4.2.
Yes
Adding Requirement 1.5 is a significant revision and raises questions as to how broadly an accuracy or equivalent parameter requirement and associated documentation would need to be addressed by entities and/or will be measured for compliance. Discussion on this new requirement does not seem to be addressed anywhere in the FAQ or Supplementary Reference documents. Additionally, to the best of our knowledge, the need for such a requirement was not brought up as a concern or comment on the prior draft version of this standard, and in the context of a requirement need, we don’t believe it has been attributed to or actually poses any significant reliability risk. We do not believe this requirement is justified.

• R1.3 appears to be missing from the VSL for R1. • Also, it’s unclear to us what the expectation is for compliance documentation for “monitoring attributes and related maintenance activities” in R1.4 and “calibration tolerances or other equivalent parameters” in R1.5. This is fairly straightforward for relays, but not for other component types. • R4 – More clarity must be provided on the expectation for compliance documentation. This is a High VRF requirement, and there may only be a small number of maintenance-correctable items, hence a significant exposure to an extreme penalty.
No
Yes
There are typographical errors on the FAQ Requirements Flowchart (should be R4.1.1 and R4.1.2 instead of R4.4.1 and R4.4.2).
Yes
• We have previously commented that the FAQ and Supplementary Reference documents should be made part of this standard. If that cannot be done, then more of the information in those documents needs to be included in the requirements in the standard to provide clarity. Compliance will only be measured against what is in the standard, and we need more clarity. • R1.4 and R1.5 need more information to provide clarity for compliance. It’s unclear to us what the expectation is for compliance documentation for “monitoring attributes and related maintenance activities” in R1.4 and “calibration tolerances or other equivalent parameters” in R1.5. This is fairly straightforward for relays, but not for other component types. Either provide clarity or delete these requirements. • R4.2 – it is critical that more clarity be provided for R1.5 so that we can also understand what the compliance expectation is for R4.2 • M4 – Need to clarify that these pieces of evidence are all “or”, not “and” (i.e. any of the listed examples are sufficient for compliance). We reiterate the need for additional clarity on R1.5 and R4.2 such that compliance can be demonstrated for all component types. • Table 2 – We are fairly

clear on the expectation for relays, but need more clarity on the expectation for other component types. Also, need to change the phrase “corrective action can be taken” to “corrective action can be initiated”, consistent with the Supplementary Reference document.

Electric Market Policy
Mike Garton
Yes
Dominion does not feel that clarity has been added to the tables. A numbering structure should be added to the table for referencing each task prescribed. The tables should more clearly designate and separate time based versus performance based tasks. Additionally, Table 1-4 contains, in several places, an activity to “Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline.” This seems to suggest that each time the batteries are checked, the measured cell/unit internal ohmic value should agree with some baseline value. This appears to be overly prescriptive as the values reading-to-reading should fall within the tolerances established per Requirement R1.5, not equal a baseline. The activities for other component types are not this prescriptive.
No
VSL R3. How do you measure a percentage of countable events over a period of time? How are you to determine what the total population to be considered? An entity should not be penalized if they are following their program, correcting issues, and documenting all actions, even if there is a high failure rate in an instance.
Yes
The document on page 3 states that data available from EPRI (et.al) was utilized by the Standard Drafting Team; however, there are no references to EPRI documents in Section 16. Suggest including EPRI references for completeness.
Yes
The FAQ’s do not appear to have kept up with the current draft Standard. For example, Question B under Section 2 for Protective Relays, refers to the use of the word “Restoration” in the definition of a Protection System Maintenance Program. The current definition uses the word “Restore.” Additionally, Answers B, I, and J under Section 2 for Protective Relays each refer to Requirement R4.3, which in not in the current Standard. Suggest a final edit of the FAQ’s to clean-up these type of issues.
Yes
1. The draft to PRC-005-2 contains defined terms that upon approval will remain with the standard rather than being moved to the Glossary of Terms. These terms when used in the Requirements are not designated in any way (e.g., capitalization, bold, etc.) to point the reader back to the in-standard definition. Need to explicitly state the intent of the SDT to either (1) use the newly defined term “Protection System (modification)” only in this standard (PRC-005-2) or (2) replace the existing definition of the existing term in the “Glossary of Terms Used in NERC Reliability Standards” with the proposed definition for the existing term. 2. The language used in Footnote 1 on Attachment A does not agree with the definition of Countable events provided elsewhere in the draft standard. Suggest footnote be removed. 3. Requirement R1.5 uses the phrase “or other equivalent parameters” which is confusing. Suggest replacing with “or acceptance criteria.” 4. Requirement R1.5 should read as follows: “Identify calibration program.” The currently proposed language focuses on specific calibration tolerances and acceptance parameters. These tolerances are developed on a per device, per location basis and would be captured at a procedural level, not a program level. To add this at a program level would only complicate the program and would not lend any improvement to the reliability of the bulk electric system. We recommend maintaining a general calibration requirement, similar to what is stated above, for an entity to develop their calibration program. 5. Requirement 2 Component should be replaced with Component Type. Creating a program to monitor the equipment at this level of equipment would not add any value to the bulk electric system as all components should already be included in component type maintenance tasks. Recommend removing the definition of Component. 6. The requirement to address “monitoring attributes” in Requirement 2 for time based maintenance program is unclear, onerous and unnecessary for a reliable protection system program. 7. Requirement (R4) should identify correctible maintenance issues not the resolution of these issues. The language in R4.2 should strike correcting maintenance issues related

to R1.5 and instead state: Any maintenance correctible issues found during the maintenance activity should be identified" 8. Table 1.2 change time frame from 3 months to 3 years.

Yes
Table 1-4 requires an activity to verify the state of charge of battery cells. There are no possible options for meeting this requirement listed in the FAQ document. Unlike other terms used in the standard, this term is not mentioned or defined in the FAQ. To comply with this standard, the SDT needs to provide more guidance. For example, for VLA batteries the measured specific gravity could indicate state of charge. For VRLA batteries, it is not as clear how to determine state of charge, but possibly this can be determined by monitoring the float current.

R1 Lower - We suggest including a second part as follows: "Failed to identify calibration tolerances or other equivalent parameters for one Protection System component type that establish acceptable parameters for the conclusion of maintenance activities. " R1 Moderate – We suggest similar to the Lower VSL but catering for two Protection System component types. R1 High - We suggest changing the wording of the 3rd part to match the requirement and to cater for more than two Protection System component types. Editorial Comment to Severe VSL for R3: In part 3, replace "less" with "fewer".
No
No
Yes
Requirement R1, Part 1.5 is vague and needs clarification. It is not clear what "Identify calibration tolerances or other equivalent parameters" means and this may be subject to different interpretations by entities and compliance enforcement personnel. Additionally, in the Implementation plan for Requirement R1, we recommend changing "six" to "fifteen" to restore the 3-month time difference between the durations of the implementation periods for jurisdictions that do and don't require regulatory approval, which existed in the previous draft. This change will ensure equity for those entities located in jurisdictions that do not require regulatory approval as is the case here in Ontario. More importantly it supports the IESO's strong belief in the principle that reliability standards should be implemented in an orderly and coordinated fashion across regions to ensure system reliability is not compromised.
Individual

Table 1.5 (Control Circuitry), row 4, indicates a maximum interval of 12 years for unmonitored control circuitry, yet other portions of control circuitry have a maximum interval of 6 years. AEP does not understand the rationale for the difference in intervals, when in most cases, one verifies the other.

Also, unmonitored control circuitry is capitalized in row 4 such that it infers a defined term. In the first row of table 1-4 on page 16, it is difficult to determine if it is a cell that wraps from the previous page or is a unique row. This is important because the Maximum Maintenance Intervals are different (i.e. 18 months vs 6 years). It is difficult to determine to which elements the 6 year Maximum Maintenance Interval applies. AEP suggests repeating the heading “Monitored Station dc supply (excluding UFLS and UVLS) with: Monitor and alarm for variations from defined levels (See Table 2):” for the bullet points on this page.
No
The VSL table should be revised to remove the reference to the Standard Requirement 1.5 in the R1 “High” VSL. All four levels of the VSL for R2 make reference to a “condition-based PSMP.” However, no where in the standard is the term “condition-based” used in reference to defining ones PSMP. The VSL for R2 should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term “condition-based” within the Standard Requirements and Table 1. In multiple instances, Table 1 uses the phrase “No periodic maintenance specified” for the Maximum Maintenance Interval. Is this intended to imply that a component with the designated attributes is not required to have any periodic maintenance? If so, the wording should more clearly state “No periodic maintenance required” or perhaps “Maintain per manufacturers recommendations.” Failure to clearly state the maintenance requirement for these components leaves room for interpretation on whether a Registered Entity has a maintenance and testing program for devices where the Standard has not specified a periodic maintenance interval and the manufacturer states that no maintenance is required.
Yes
With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications: Section 5 of the Supplementary Reference, refers to “condition-based” maintenance programs. However, no where in the standard is the term “condition-based” used in reference to defining ones PSMP. The Supplementary Reference should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term “condition-based” within the Standard Requirements and Table 1. Section 15.7, page 26, appears to have a typographical error “...can all be used as the primary action is the maintenance activity...” Figure 2 is difficult to read. The figure is grainy and the colors representing the groups are similar enough that it is hard to distinguish between groups.
Yes
With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications: The section “Terms Used in PRC-005-2” is blank and should be removed as it adds no value. Section I.1 and Section IV.3.G reference “condition-based” maintenance programs. However, no where in the standard is the term “condition-based” used in reference to defining ones PSMP. The FAQ should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term “condition-based” within the Standard Requirements and Table 1. The second sentence to the response in Section I.1 appears to have a typographical error “... an entity needs to and perform ONLY time-based...”.
Standards Requirement 1.5 and the reference to R1.5 in Requirement 4.2 should be removed. Specifying calibration tolerances for every protection system component type, while a seemingly good idea, represents a substantial change in the direction of the standard. It would be very onerous for companies to maintain a list of calibration tolerances for every protection system component type and show evidence of such at an audit. AEP believes entities need the flexibility to determine what acceptance criteria is warranted and need discretion to apply real-time engineering/technician judgment where appropriate. Three different types of maintenance programs (time-based, performance-based and condition-based) are referenced in the standard or VSLs, yet the time-based and condition-based programs are neither defined nor described. Certain terms defined within the definition section (such as Countable Event or Segment) only make sense knowing what those three programs entail. These programs should be described within the standard itself and not assume a

knowledge of material in the Supplementary Reference or FAQ. “Protective relay” should be a defined term that lists relay function for applicability. There are numerous ‘relays’ used in protection and control schemes that could be lumped in and be erroneously included as part of a Protection System. For example, reclosing or synchronizing relays respond to voltage and hence could be viewed by an auditor as protective relays, but they in fact perform traditional control functions versus traditional protective functions. The Data Retention requirement of keeping maintenance records for the two most recent maintenance performances is a significant hurdle for any owners to abide by during the initial implementation period. The implementation plan needs to account for this such that Registered Entities do not have to provide retroactive testing information that was not explicitly required in the past.

The following question concerns Table 1-3. Our testing program includes “impedance testing” of the current transformers (CTs) along with insulation testing of the wiring and CT secondary. Impedance testing involves impressing an increasing voltage on the secondary of the CT (with primary open circuited) until 1 (one) ampere flows. This method determines the “knee” of the saturation curve that is used as a benchmark for comparison to previous testing and other CTs. This procedure has successfully identified CT problems over the past several decades. We believe this procedure to be adequate. Does the SDT agree that this method is sufficient to meet the testing requirements of Table 1-3 and that a current comparison is not needed in addition to this testing? Another variation of this is for voltage device compliance. Table 1-3 indicates that we should verify the correct voltages are received by the relay. This means that the VT would need to be energized and we would measure the secondary voltages to compare with others. Power plant relay testing is normally performed during plant outages when this measurement cannot be done. Some plants do not allow any testing while the unit is on line. It would seem that the standard would be written to allow some other type of testing to be performed other than the measurement test. For Table 1-1 Row 1, we believe the intent is to verify that settings are as specified for non-microprocessor relays and microprocessor relays alike. If this is the case, consider adding “Verify that settings are as specified” as a bullet under the headings for non-microprocessor relays and microprocessor relays. Splitting the tables into separate sections for Protective Relays, Communication Systems, VT and CTs, and Station D.C. Supply helped the clarity.
Yes
Yes
Auxiliary Relay Testing: We repeat our objection to the 6 year requirement for testing of auxiliary relays. The STD response to our previous objection was: Please see new Table 1-5. The SDT believes that mechanical solenoid-operated devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-based maintenance is an option to increase the intervals if the performance of these devices supports those intervals.

Auxiliary relays are, of course, electromechanical relays, but much less complicated than impedance, differential or even time-overcurrent electromechanical relays. It has been our experience that trip failures are rare and that our present 10 year control, trip tests, and other related testing are sufficient in verifying the integrity of the scheme. Section 8.3 of the Supplemental Reference notes statistical surveys were done to determine the maintenance intervals. Were auxiliary relays included in these surveys in a such a way to verify that they indeed require a 6 year maintenance interval? We recommend they be considered part of the control circuitry, with a 12 year test cycle. High Speed Ground Switch Testing We repeat our recommendation that the standard state that a high speed ground switch is an interrupting device. We also recommend that testing requirements for High-Speed ground switches be clearly stated in the standard. Section 15.3 of the Supplemental Reference contains the following: It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device if this ground switch is utilized in a Protection System and forces a ground fault to occur that then results in an expected Protection System operation to clear the forced ground fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is “…applied on, or designed to provide protection for the BES…” then this device needs to be treated as any other Protection System component. The control circuitry would have to be tested within 12 years and any electromechanically operated device will have to be tested every 6 years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit then the solenoid triggering unit can easily be tested without the actual closing of the ground blade. We disagree that a high-speed ground switch can be adequately tested by disconnecting the solenoid triggering unit. The ability of the trip coil to “operate the circuit breaker” must be verified per Table 1-5 Row 1. The ability of the “solenoid triggering unit” to operate the ground switch should be required also. A high-speed ground switch is a unique device. Its maintenance requirements should be specifically included in the standard itself. Based on Draft 3 of the standard, this is a electromechanically operated device and would have to be tested every 6 years. A logical location would be in Table 1-5. Is there test data to support the test method of disconnecting the solenoid triggering unit?
No
Yes
5.1 We would like some further clarification on PRC-005-2 Draft 3, specifically on the statement in Table 1-4 for unmonitored station DC supply with VLA batteries. In the table it is mentioned that we are to perform either a capacity test every six years or verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline, the latter statement is a little vague and needs further clarification with regards to the expectations from the standard. Please describe an acceptable method of establishing a baseline “measured cell/unit internal ohmic value” We would like to know what exactly is required. We measure the cell internal ohmic value on an annual basis every 12 months, is that enough? What are the comparison parameters with regards to battery baseline? At what percent should we look to replace the cell? 5.2 Is a battery system that only supplies the SCADA RTU considered part of the protective system if alarms for the monitored protective systems utilize that SCADA RTU?

No
The wording “Component Type” is not necessary in each title. Just the equipment category should be listed--what is now shown as “Component Type - Protective Relay”, should be Protective Relay. However, Protective Relay is too general a category. Electromechanical relays, solid state relays, and microprocessor based relays should have their own separate tables. So instead of reading Protective Relay in the title, it should read Electromechanical Relays, etc. This will lengthen the standard, but will simplify reading and referring to the tables, and eliminate confusion when looking for information. The “Note” included in the heading is also not necessary. “Attributes” is also not necessary in the column heading, “Component” suffices.
No
Because all the requirements deal with protective system maintenance and testing, violations could directly cause or contribute to bulk electric system instability, etc., the VRFs should all be “High”. The

Time Horizons should all be “Operations Planning” because of the immediacy of a failure to meet the requirements. For the R1 Lower VSL, include a second part to read: Failed to identify calibration tolerances or other equivalent parameters for one Protection System component type that establish acceptable parameters for the conclusion of maintenance activities. For the R1 Moderate VSL, suggest similar wording as for the Lower VSL but specifying two Protection System component types. For the R1 High VSL, suggest changing the wording of the 3rd part to be similar to the Lower VSL to match the requirement and to cater for more than two Protection System component types. For the R3 Severe VSL, in part 3, replace “less” with fewer.
No
Yes
See response to Question 5 below.
In general, the standard is overly prescriptive and complex. It should not be necessary for a standard at this level to be as detailed and complex as this standard is. Entities working with manufacturers, and knowledge gained from experience can develop adequate maintenance and testing programs. Why are “Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation)…” not included? The output contacts from these devices are oftentimes connected in tripping or control circuits to isolate problem equipment. Due to the critical nature of the trip coil, it must be maintained more frequently if it is not monitored. Trip coils are also considered in the standard as being part of the control circuitry. Table 1-5 has a row labeled “Unmonitored Control circuitry associated with protective functions”, which would include trip coils, has a “Maximum Maintenance Interval” of “12 Calendar Years”. Any control circuit could fail at any time, but an unmonitored control circuit could fail, and remain undetected for years with the times specified in the Table (it might only be 6 years if I understand that as being the trip test interval specified in the table). Regardless, if a breaker is unable to trip because of control circuit failure, then the system must be operated in real time assuming that that breaker will not trip for a fault or an event, and backup facilities would be called upon to operate. Thus, for a line fault with a “stuck” breaker (a breaker unable to trip), instead of one line tripping, you might have many more lines deloaded or tripped because of a bus having to be cleared because of a breaker failure initiation. The bulk electric system would have to be operated to handle this contingency. In reference to the FAQ document, Section 5 on Station dc Supply, Question K, clarification is needed with respect to dc supplies for communication within the substation. For example, if the communication systems were run off a separate battery in separate area in a substation, would the standard apply to these batteries or not? To define terms only as they are used in PRC-005-2 is inviting confusion. Although they may be unique to PRC-005-2, some or all of them may be used in future standards, some already may be used in existing standards, and may or may not be deliberately defined. Consistency must be maintained, not only for administrative purposes, but for effective technical communications as well. What is the definition of “Maintenance” as used in the table column “Maximum Maintenance Interval”? Maintenance can range from cleaning a relay cover to a full calibration of a relay. A control circuit is not a component, it is made up of components. Sub-requirement 1.5 needs to be clarified. It is not clear what “Identify calibration tolerances or other equivalent parameters…” means, and may be subject to different interpretations by entities and compliance enforcement personnel. In the Implementation plan for Requirement R1, recommend changing “six” to fifteen. This change would restore the 3-month time difference that existed in the previous draft, between the durations of the implementation periods for jurisdictions that do and do not require regulatory approval. It will ensure equity for those entities located in jurisdictions that do not require regulatory approval, as is the case in Ontario. The ‘box’ for “Monitored Station dc supply…” in Table 1-4 is not clear. It seems to continue to the next page to a new box. There are multiple activities without clear delineation.

VRF’s: The definition of a Medium Risk Requirement included on page 8 of the SAR states: "A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system." The PSMP does not "directly" affect the electrical state or the capability of the bulk electric system. A failure of a Protection System component is required to "directly" affect the BES. Therefore, the PSMP has only an "indirect" affect on the electrical state or the capability of the BES. Requirements R1 through R3 and their subparts are administrative in nature in that they are comprised entirely of documentation. Therefore, I recommend changing the Violation Risk Factor of Requirements R1, R2, and R3 to Lower to be consistent with the Violation Risk Factors defined in the SAR. VSL’s: R2: Tables 1-1 through 1-5 refers to time-based maintenance programs. I recommend changing "condition-based" to "time-based" in all four severity levels. SAR Attachment B - Reliability Standard Review Guidelines states that violation severity levels should be based on the following equivalent scores: Lower: More than 95% but less than 100% compliant Moderate: More than 85% but less than or equal to 95% compliant High: More than 70% but less than equal to 85% compliant Severe: 70% or less compliant I recommend revising the percentages of the violation severity levels to be consistent with the SAR. R3: The performance-based maintenance program identified in PRC-005 Attachment A provides the requirements to establish the technical justification for the initial use of a performance-based PSMP and the requirements to maintain the technical justification for the ongoing use of a performance-based PSMP. However, it appears the VSLs for Requirement R3 only addresses the ongoing use of the technical justification. I recommend revising the VSLs for R3 to include the initial use of the technical justification. Item 2) of R3 Severe VSL is a duplicate of Item 2) of R3 Lower VSL. This item is administrative in nature therefore I recommend deleting Item 2) from R3 Severe VSL. The first and third bullets of item 4) of R3 Severe VSL are administrative in nature and should be moved to the Lower VSL R4: SAR Attachment B - Reliability Standard Review Guidelines states that violation severity levels should be based on the following equivalent scores: Lower: More than 95% but less than 100% compliant Moderate: More than 85% but less than or equal to 95% compliant High: More than 70% but less than equal to 85% compliant Severe: 70% or less compliant I recommend revising the percentages of the violation severity levels to be consistent with the SAR.
Yes
The Supplemental Reference Documents identified are unapproved and in draft form. I believe that only approved documents should be referenced in the Standard. Therefore, I recommend updating the Supplemental Reference Documents section with approved versions of the documents.
No
Yes
Definitions: The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC

standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend deleting the words "and proper operation of malfunctioning components is restored." from the first sentence of the PSMP definition. I believe that failure to do so exceeds the scope of the SAR. The definition of a Countable Event should clearly state whether or not multiple conditions on a single component will count as a single Countable Event or as multiple Countable Events. For example, a single relay fails its undervoltage setting and its under frequency setting. Is this one Countable Event or two Countable Events? Applicability Part 4.2.2: The ERO does not establish underfrequency load-shedding requirements. Those requirements will be established by Reliability Standard PRC-006-1 when it is approved by FERC. I recommend changing Accountability Part 4.2.2. to "...installed to provide last resort system preservation measures." (Note this wording is consistent with the Purpose of PRC-006-0.) Applicability Part 4.2.5.4 and 4.2.5.5: Station Service transformers provide energy to plant loads and not the BES. If these plant transformers are included, why not include the rest of the plant systems? I recommend deleting Applicability Part 4.2.5.4 and 4.2.5.5. Requirement R1 Part 1.2: The wording of the first sentence is unclear about what information is required. For example, I could state in my PSMP that: "All Protection System component types are addressed through time-based, performance-based, or a combination of these maintenance methods" and be compliant with the Requirement. I recommend re-wording the first sentence to state: "Identify which maintenance method is used to address each Protection System component type. Options include time-based, performance-based (per PRC-005 Attachment A), or a combination of time-based and performance-based (per PRC-005 Attachment A)." Note that PRC-005 Attachment A does not address a combination of maintenance methods and therefore the second reference in the first sentence should be removed if the original wording is retained. Requirement R1 Part 1.4: The column titles in Tables 1-1 through 1-5 have been revised to “Component Attributes” and “Activities”. I recommend changing "monitoring attributes" to "component attributes" and "maintenance activities" to "activities" to be consistent with the Tables. Requirement R1 Part 1.5: Maintenance acceptance criteria for a given Protection System component type may very depending on the manufacturer, model, etc.. Including all acceptance criteria in the PSMP document will over-complicate the program document. I recommend clarifying Part 1.5 to allow the incorporation of device-specific acceptance criteria in the applicable evidentiary documentation. One possible option is to add a second sentence as follows: "The calibration tolerances or other equivalent parameters may be included with the maintenance records." Note that a personal preference would be to use the phrase “acceptance criteria” instead of “calibration tolerances or other equivalent parameters”. Requirement R4: The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend deleting the words "including identification of the resolution of all maintenance correctable issues" from the first sentence of the Requirement. I believe that failure to do so exceeds the scope of the SAR. Requirement R4 Part 4.2: What is considered sufficient verification of parameters? Does this require an engineer or technician signature or simply an indication of pass/fail? The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend re-wording

Requirement 4, Part 4.2 to state: "Verify that the components are within the acceptable parameters established in accordance with Requirement R1, Part 1.5 at the conclusion of the maintenance activities." I believe that failure to do so exceeds the scope of the SAR. Measurement M2: Can a single specification document suffice for similar relay types such as one document for SEL relays? For trip circuit monitoring can a standard document be used for a group of similar schemes ? Measurement M4: I assume this is not an all inclusive list of potential forms of evidence. Please clarify what is meant by "such as". Does this mean that: 1) Any one item is sufficient?; 2) Certain combinations of evidence are necessary? If so, what combinations?; 3) Are other items that are not identified here acceptable? Measurement M4 repeatedly refers to "dated" evidence. However, current audit expectations include either performer signatures or initials on the evidence in addition to the dates. Please revise Measurement M4 to clearly state the expectations regarding performer signatures or initials on the evidence documents. The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend deleting the words: "and initiated resolution of identified maintenance correctable issues" from the last sentence of Measurement M4. I believe that failure to do so exceeds the scope of the SAR. Compliance Part 1.3: Tables 1-1 through 1-5 refers to time-based maintenance programs. I recommend changing "performance-based" to "time-based" in the last sentence of the third paragraph. The last paragraph of Part 1.3 of the Compliance Section states: "The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records." This appears to be a requirement of the Compliance Enforcement Authority however they are not identified in Section 4 Applicability of the Standard. It is also in conflict with the SAR Attachment B - Reliability Standard Review Guidelines which states on page SAR-10: "Do not write any requirements for the Regional Reliability Organization. Any requirements currently assigned to the RRO should be re-assigned to the applicable functional entity." I recommend deleting the last paragraph of Part 1.3 of the Compliance Section to avoid conflict with the SAR. Table 1-1: The Activity of row 1 states: “Verify operation of the relay inputs and outputs that are essential to …”. Please clarify what is meant by “operation of” the relay inputs and outputs. What is the criteria to determine if something is “essential”? The first line of row 2 has a double colon. Please delete one of them. For the second bullet of row 2 column 1, please clarify what is meant by the last part of this sentence "that are also performing self monitoring and alarming" and how it relates to the voltage and current sampling required. It appears the self monitoring is required in the first bullet. For the first bullet of row 2 column 3, many relay settings may not be essential to the protective function of the relay. I recommend revising the first bullet to: “Settings that are essential to the proper function of the protection system are as specified.” The format of the Activities column for all three rows are different. Please reformat them to be consistent. My preference is the second row. Table 1-2: Row 1 Column 2, verifying the functionality of communications systems on a 3 calendar months basis is excessive and unnecessary. Suggest changing the Maximum Maintenance Interval to either 6 calendar months or semi-annual. Row 2 Column 1, please provide examples of typical communications systems that fit into this category, e.g.,Mirror Bit or Guard systems? The words “such as” are used repeatedly. Please clarify what is meant by "such as". Is this left up to the Utility to define in their PSMP? Table 1-5: The Activity for row 1 requires verification that each trip coil is able to operate the device. If a control circuitry contains multiple trip coils, it is not always possible to determine which trip coil energized to trip the device. I recommend changing "each trip coil" to "at least one trip coil". Please clarify what is meant by an "Electromechanical trip" device in row 3. Row 3 column 3, does this mean verify the trip contact on the device operates properly but not verify the trip circuit wiring from this contact to the trip coil since the trip circuit is tested in the row below? It is difficult to separate the meaning in these two rows. Row 4 column 3 requires verification of all paths of the control and trip circuits. Please clarify if this includes the control circuitry of Protection Systems located at the other end of a line if the device utilizes a remote trip scheme?

Yes
Yes
Yes
Some of the maintenance tasks need to be defined: - The state of charge of each individual cell may need to be better defined. There are means to verify the state of charge of the entire bank, but not each individual cell. - Battery continuity needs to be defined. - There is no mention to what the limits are for the "other equivalent parameters" when performing maintenance activities, just that they need to be identified. There are a large number of battery models which creates a large contrast of parameters, which cannot be grouped together. It is also difficult to get baseline values for older battery models which could result in moving baselines until they become more accurate as the database is populated. - If corrective actions are required, is there a maximum allowable duration for when they need to be resolved? The maximum allowable maintenance for station batteries (impedance testing and performance/service testing) is too frequent and suggest an extension or alternative testing methods to stay in compliance. The frequency with which BPA performs the 18 month maintenance tasks as prescribed in the standard are on a 24 month interval along with visual inspections and voltage measurements monthly. BPA has seen success with this maintenance program with the ability to identify suspect cells or entire banks with adequate time to perform corrective actions such as repairs or replacements. BPA also does not perform routine capacity testing, this is an as required maintenance task to confirm/validate our other test results if needed. BPA would like to see clarification for these issues before we can fully support this standard.

Armin Klusman
CenterPoint Energy
Yes
Yes
The need for an FAQ document, in addition to an extensive Supplementary Reference document, illustrates the complexity and impracticality of the proposed Standard. CenterPoint Energy does not support the development of an additional type of document, that is, the FAQ document. CenterPoint Energy recommends eliminating the FAQ document and using only a Supplementary Reference" document. This would also provide the benefit of not having contradictory information in the two documents.
Yes
(a) CenterPoint Energy cannot support this proposed Standard. Any standard that requires a 35 page Supplementary Reference document and a 37 page FAQ – Practical Compliance and Implementation document, in addition to extensive tables in the Standard, is much too prescriptive and complex to be practically implemented. (b) CenterPoint Energy is opposed to approving a standard that imposes unnecessary burden and reliability risk by imposing an overly prescriptive approach that in many cases would "fix" non-existent problems. To clarify this last point, CenterPoint Energy is not asserting that maintenance problems do not exist. However, requiring all entities to modify their practices to conform to the inflexible approach embodied in this proposal, regardless of how existing practices are working, is not an appropriate solution. Among other things, requiring entities to modify practices that are working well to conform to the rigid requirements proposed herein carries the downside risk that the revised practices, made solely to comply with the rigid requirements, degrade reliability performance. (c) CenterPoint Energy is very concerned that a large increase in the amount of

documentation will be required in order to demonstrate compliance - with no resulting reliability benefit. CenterPoint Energy believes this Standard could actually result in decreasing system reliability, as the Standard proposes excessive maintenance requirements. The following is included in the Supplementary Reference document (page 8): “Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it.” System reliability can be even further reduced by the number of transmission line and autotransformer outages required to perform maintenance. (d) The following is included in the FAQ – Practical Compliance and Implementation document: “PRC-005-2 assumes that thorough commission testing was performed prior to a protection system being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components such that a properly built and commission tested Protection System will continue to function as designed over its service life.” CenterPoint Energy believes some proposed requirements, such as wire checking a relay panel, do not conform to this statement. CenterPoint Energy’s experience has been that panel wiring does not degrade with age and service and that problems with panel wiring, after thorough commissioning, is not a systemic issue.

FAQ Protective Relays 2.D: The last sentence is not consistent with the discussions at the “March 2010, Standard Drafting Team Meeting, Project 2007-17”. The understanding from that meeting was that the relay settings would be verified that the “as left” settings were the same as the “as found” settings and that the intent was not to verify the settings against a Master Record. Therefore the intent is that the tester will verify that no setting changes were made as part of the testing process. Please include this clarification with the language in the standard. FAQ Group by Type of Maintenance Program 2.B: We agree with the use of either the in-service date or the commissioning date to start the initial due date calculation for maintenance. Please include this clarification with the language in the standard.
Yes
ATC recognizes the substantial efforts that the SDT has made on PRC-005 and appreciate the SDT’s modifications to this Standard based on previous comments made. ATC looks forward to continuing to have a positive influence on this process via the comment process, ballots and interaction with the SDT. ATC was very close to an affirmative vote on this Standard prior to the unanticipated changes that appeared in this most recent posting. These changes introduce a significant negative impact from ATC’s perspective. Therefore, ATC is recommending a negative ballot in the hope that our concerns regarding R 1.5 and R 4.2 and other clarifications will be included with the standard The two items within the proposed Standard that we take exception to are not directly related to implementing FERC Order 693. Rather, it is the overly prescriptive nature with respect to the “how” as outlined in the proposed Standard that ATC takes exception... To improve and find the proposed Standard acceptable, ATC would like to see the following modifications: 1. Change the text to require the actuation of a single trip coil (row 1 of table 1.5). This would satisfy the intent to exercise the mechanism on a regular schedule, given that the mechanism binding is a much more likely source of a coil failure. The balance of trip coils could then be tested as part of routine breaker maintenance. 2. Eliminate the additional requirements introduced by the addition of R1.5 and the associated modifications to R4.2. The additional documentation required for the range of each element is typically incorporated into the pass/fail mechanism of the existing test equipment (which is reflective of the manufacturer recommendations) used to conduct these tests. Therefore, requiring the assembly of this additional documentation from each entity would: a. Be duplicative and voluminous

as it would require us to track thousands of additional data points due to the variability in element ranges by relay manufacturer, model number and vintage. b. Not add to the reliability of the system as this function is already being performed on a collective basis.

No
We do not agree with the addition of Requirements 1.5 and 4.2 without work on or review by the Power System Maintenance and Testing Drafting Team. While some maintenance activities on some component types (such as calibration testing of electromechanical relays) translate inherently well into these requirements,the requirements of tolerances and documentation do not fit as well to all maintenance activities on other types of equipment considered part of the protective system. These requirements need to be worked on through the drafting team to make them viable and effective for all protective system component types.

Yes
1. Table 1-3 states, “are received by the protective relays”. Does this require that the inputs to each individual relay must be checked, or is it sufficient to verify that acceptable signals are received at the relay panel, etc? 2. Relative to Table 1-5, the activities will likely require that system components be removed from service to complete those activities. If the changes to the BES definition (per the FERC Order) causes system elements such as 138 kV connected distribution transformers to be considered as BES, these components can not be removed from service for maintenance without outaging customers. The standard must exempt these components from the activities of Table 1-5 if the activity would result in deenergizing customers. 3. For the component types addressed in Tables 1-3 and 1-5, the requirements may cause entities to identify components very differently than they are currently doing, and doing so may take several years to complete. The Implementation Plan for R1 and R4 is too aggressive in that it may not permit entities to complete the identification of discrete components and the associated maintenance and implement their program as currently proposed. We propose that the Implementation Plan specifically address the components in Table 1-3 and 1-5 with a minimum of 3 calendar years for R1 and 12 calendar years after that for R4. 4. As for the interval in Table 1-4 regarding the battery terminal connection resistance, we believe that an 18-month interval is excessively frequent for this activity, and suggest that it be moved to the 6-calendar-year interval. 5. In Table 1-4, we currently re-torque all of the battery terminal connections every 4-years, rather than measuring the terminal connection resistance to determine if the connections are sound. Disregarding the interval, would this activity satisfy the “verify the battery terminal connection resistance” activity?

Yes
The draft standard is too perscriptive. Requirement R1, Part 1.5 would be overwhelming if approved. Requirement R1, Part 1.5 should be deleted. Requirement R4, Part 4.2 phrase "established in accordance with Requirement R1, Part 1.5" should be deleted. The standard without these additional requirements would be sufficient to establish that the Protection System is maintained and protects the BES. Table 1-2 Component Type Communications Systems Maximum Maintenance Interval of 3 Calendar Months to verify that the communications system is functional for any unmonitored communications system is unyielding. Most communication failures are caused by power supply failures which Next Era does monitor. Based on experience and monitoring of communication power supplies, 12 calendar months would be adequate. The maximum maintenance interval should be changed from 3 calendar months to 12 calendar months. Table 1-4, Component Type Station dc Supply Maximum Maintenance Interval of 3 Calendar Months to inspect electrolyte levels on “Any unmonitored station dc supply not having the monitoring attributes of a category below. (excluding UFLS and UVLS)” is too stringent. Verifying battery charger float voltage every 18 calendar months is sufficient to prevent excessive gassing and water loss of battery cells. The maximum maintenance interval should be changed from 3 calendar months to 6 calendar months. Table 1-4, Component Type Station dc Supply Maximum Maintenance Interval of 3 Calendar Months to measure the internal ohmic values on “Unmonitored Station dc supply with Valve Regulated Lead-Acid (VRLA) batteries that does not have the monitoring attributes of a category below. (excluding UFLS and UVLS)” is too stringent. With the standard’s requirement to verify the float voltage every 18 calendar months, measuring the internal ohmic values every 6 calendar months would be adequate. The maximum maintenance interval should be changed from 3 calendar months to 6 calendar months.

(3X) --- On Page 14, Section G, change the text "The first maintenance activity" to The capacity testing activity". --- On Page 14, Section G, change the text "The second maintenance activity", to The internal ohmic measurement activity". --- On Page 14, Section H, correct the reference of Table 1 to Table 1-4. (1X) --- On Page 17, Section C, correct the reference of Table 1 to Table 1-5. (1X) --- Please address what is meant by "Battery terminal connection resistance" on Page 14, Table 1-4 of the standard.
Yes
• Please consider retaining the definitions stated to be moved to the NERC Glossary – they would be valuable to entities in the standard. • On Page 5, Section 1.2, please consider changing "or a combination of these maintenance methods (per PRC-005-Attachment A)." to "or a combination of these two maintenance methods." • On Page 5, Section 1.5: recommend deleting this section - the subjectivity of what is an acceptable value for component testing makes this requirement un-valuable. • On Page 5, Section 4.2, it is recommended that the requirement be the following: Either verify that the component performance is acceptable at the conclusion of the maintenance activities or initiate resolution of any identified maintenance correctable issue. • On Page 5, Measure M1, replace 1.5 with 1.4 (after eliminating Requirement 1.5) • On Page 6, Section 1.3, replace the existing Data Retention text with the following: The TO, GO, and DP shall each retain documentation for the longer of the these time periods: 1) the two most recent performances of each distinct maintenance activity for the Protection System component, or (2) all performances of each distinct maintenance activity for the Protection System component since the previous scheduled audit date. The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records. • On Page 10, Section F, please correct the revision information for the documents listed. • On Pages 14 & 15, Table 1-4, move the bottom row to the next page so that it is easier to see that the maintenance activities are an "either/or" option. • On Page 17, Table 1-5, it seems that the 12 calendar year interval activities would automatically be included in the 6 calendar year activity for verifying the electrical operation of electromechanical trip and auxiliary devices. Is the 12 year requirement superfluous? • On Page 19, Attachment A, it is recommended to delete the footnote #1 since the definition is given already on Page 2.

NERC Staff
Mallory Huggins
Yes
Yes
In section 2.3, NERC staff recommends noting that the present NERC Glossary definition of Bulk Electric System will be revised in response to FERC Order No. 743. In Section 2.4, NERC staff recommends changing the phrase "relays that use measurements of voltage, current, frequency and/or phase angle" with "protective relays that respond to electrical quantities" for consistency with recent changes to the proposed definition of Protection System.
Yes
At a minimum, the response to Question II.1.A should be revised to reflect the present revision of Requirement R1. In the current proposed response to the FAQ, the answer refers to text that was deleted from Requirement R1 in the current posting of the standard; i.e., this standard covers protective relays "that use measurements of voltage, current and/or phase angle to determine anomalies and to trip a portion of the BES." The removal of this text from Requirement R1 makes it less clear whether the standard applies to reclosing functions and protective functions used to

supervise automatic or manual closing of a circuit breaker to ensure the voltage magnitude and phase angle difference are within specified tolerances. The drafting team also should consider whether additional specificity is required to ensure applicability is clearly defined within the standard. In the response to Question II.2.H, NERC staff notes that the word "than" should be changed to "then" in the phrase "If the component no longer performs Protection System functions than..." In the response to Question II.2.I, NERC staff recommends noting that "When a failure occurs in a protection system, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC standard(s)." The recommended text is included in the Supplementary Reference Document and inclusion in the FAQ response provides consistency and highlights obligations in other standards necessary for BES reliability. In the response to Question III.1.A, NERC staff recommends noting that the present NERC Glossary definition of Bulk Electric System will be revised in response to FERC Order No. 743. In the response to Question III.3.A, NERC staff recommends a more generic reference to NERC UFLS requirements in place of the reference to PRC-007-0, as PRC-007 will be retired pending FERC approval of PRC-006-1. In the response to Question IV.1.A (third paragraph), NERC staff recommends changing the phrase "that are certainly coming to the industry" to "may be coming to the industry" for consistency with the change to the response to Question V.4.A. Both questions appear to address the same or similar concerns.
Yes
Commissioning (Initial) Testing: During development of PRC-005-2, NERC staff has observed a trend in system disturbances involving Protection System problems that should have been identified and corrected during commissioning (initial) testing. While NERC staff recognizes that the addition of commissioning testing may be unrealistic at this stage in the standard drafting process, we want to emphasize its importance. If the SDT chooses to leave commissioning testing out at this juncture, we plan to pursue other avenues to ensure its eventual inclusion through a separate standards project. NERC staff agrees with the SDT's opinion that without commissioning testing, a registered entity responsible for compliance with this standard cannot provide proof of its interval testing period as required by the standard. As soon as the entity puts the protective scheme into service, time "0" for interval testing begins. The next testing interval would be some specific number of years in the future from time "0." An entity's failure to properly commission new protection system equipment has caused or exacerbated several recent events, greatly impacting BPS reliability. The following are examples of errors that were not detected during commissioning. These undetected errors were observed by NERC staff during event analysis and investigation activities: •Failure to apply correct relay settings. This has occurred repeatedly and has been due to improper procedures, poor document control, misapplication or miscalibration of the relay, or a combination of the above. •Failure to install the proper CT or PT ratio occurred due to poor document control practices and resulted in an undesired protection system response after the equipment was placed in service. •Failure to conduct a functional test of new control circuits to the schematic diagram resulted in an undesired protection system response after equipment was placed in service. •An incorrect CT ratio was not detected during commissioning, and the equipment was subsequently placed in service. Because in-service testing was not performed, the error remained undetected until the relay misoperated during a fault. Many of the above conditions can remain undetected for extended periods, until they are revealed by a relay misoperation during fault or heavy load conditions. The affects resulting from these cases could have been prevented with proper commissioning testing. We believe that by requiring commissioning testing for new protection system equipment, the reliability of BPS would be improved. --- Requirement 2: In Requirement 2, it is unclear what is meant by "shall verify those components possess the monitoring attributes identified in Tables 1-1 through 1-5 in its PSMP" because the use of terms in the Requirement is not consistent with the column headings used in Tables 1-1 through 1-5. It also is not clear that components need not possess all attributes; rather, they must possess all attributes consistent with the Maximum Maintenance Interval specified in an entity's PSMP. NERC staff recommends revising R2 to provide additional clarity as follows: "Each Transmission Owner, Generator Owner, and Distribution Provider that uses maintenance intervals for monitored Protection Systems described in Tables 1-1 through 1-5, shall verify those components possess the monitoring attributes Component Attributes identified in the first column of Tables 1-1 through 1-5 consistent with the Maximum Maintenance Interval specified in its PSMP."

Yes
While we agree that the clarity of the tables has improved, there are still items that warrant further clarity. In Table 1-1, references to "Verify acceptable measurement of power system input values" is made for microprocessor relays on 6 and 12 calendar year intervals. Wouldn't this also be prudent on non-microprocessor based relays as well on the 6 year interval? Also, in Table 1-3, "Verify that acceptable measurement of the current and voltage signals are received by the protective relays" is shown on a 12 calendar year interval. What is the difference between this activity and the similar activity performed in Table 1-1? In Table 1-4, this table is complex and the detailed maintenance activities in this particular table is puzzling when compared to the more generic detail in the other tables within this section. For example, an incorrect operation due to a deteriorated signal from a CT or VT has a higher probability than a failure of a battery bank to perform when called upon. In Table 1-5, Please provide clarity on the "Unmonitored Control circuitry associated with protective functions" component attribute. This would most likely be an FAQ item.
No
The VSL for R2 need to be adjusted since "Condition Based Maintenance" has been removed from the standard.
Yes
1. The discussions surrounding implementing the PSMP on pages 10 and 11 of the clean copy are troublesome for the following reasons. On Pg. 10, under Sec. 8.1, the 4th bullet item states "If your PSMP (plan) requires more activities then you must perform and document to this higher standard". This statement's use of the word "must" implies that an entity will be audited to their documented maintenance practices, even if those practices exceed the requirements of the PRC-005 standard. The PRC-005 standard, and any standard, details the minimum requirements that must be met to achieve a certain reliability goal. For example, if an entity's program states that it will do maintenance on a relay every 4 years, but the standard only requires maintenance every 6 years, the entity shall be held compliant to the standard's 6 year interval. If the entity in this example decides that in year 4 it must delay its maintenance to year six, that should be allowable since the standard PRC-005-2 requires maintenance every 6 years. 2. Since the standard no longer discusses Condition Based Maintenance, it should be removed from the reference document for consistency.
No
Yes
REQUIREMENTS Requirement R1 – Subpart 1.5 – We do not support this subpart for the following reasons and offer the following suggestions: To satisfy R1.5, a calibration tolerance or other equivalent parameter would have to be established for each item included in the definition. Many devices which may have similar functionality may also have different performance criteria that would preclude the use of a "one size fits all" calibration tolerance. Many of these criteria are provided by the manufacturer and often vary by manufacturer for a similar device. It would be very difficult to specify in your program all of the calibration tolerances or other equivalent parameters associated with the protection system components Therefore, we suggest the team delete Subpart 1.5 of Req. R1, and revise Subpart 4.2 of Req. R4 to read: "Initiate resolution of any identified maintenance correctable issues at the conclusion of maintenance activities for Protection System components." IMPLEMENTATION PLAN On pg. 2 of the implementation plan, under "Retirement of Existing Standards", the statement "The existing standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 shall be retired upon regulatory approval of PRC-005-2" is not accurate. Since the new PRC-005-2 standard allows for at least 12 months to become compliant with Requirement R1 – establish a Protection System Maintenance Program (PSMP) -the existing standards are still effective during this time. Additionally, we have concerns with the "General Considerations" describing protocols for compliance audits conducted during the allowed 12 month development period of the PSMP and that entities could specify for "each component type" whether maintenance of that component is being performed according to its maintenance program under the "retired" PRC maintenance standards or the new PRC-005-2 standard. In our view, this creates a level of compliance complexity for both the Registered Entity and Regional Entity that should be avoided in the transition to PRC-005-2. FirstEnergy proposes that the Implementation Plan state that the existing standards remain in effect for one year past applicable approval (NERC Board or Regulatory) and that they are retired coincident with the one-year transition to Requirement R1 of PRC-005-2 which would establish all Registered

Entities having a new PSMP per the expectations of PRC-005-2. At that time all entities would be required to be under the new PRC-005-2 standard and begin implementing their PSMP per the phased-in Implementation Plan for the remaining requirements. To summarize, per our above discussion we propose the team perform the following: 1. Revise the Implementation Plan section titled "Retirement of Existing Standards" section to read as follows: "The existing Standards PRC-005-1, PRC-008-0, PRC-011-0 and PRC-017-0 shall be retired on the first day of the first calendar quarter twelve months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 12 months following the Board of Trustees adoption" 2. Remove the entire "General Considerations" section from the Implementation Plan. The bulleted item under the section titled "Implementation plan for R1" has a discrepancy in the time allowed to implement R1 between entities applicable to regulatory approval of the standard versus those in jurisdictions where no regulatory approval is needed and base their adherence per the Board of Trustee adoption. Please revise to reflect a 12 month transition period for each. DEFINITIONS Maintenance Correctable Issue - This is a maintenance standard and this concept gets into the long term repair activities. Is this really appropriate in this standard? If NERC feels repairing is critical to BES reliability, then they should probably initiate a standard in that area. Component – Regarding the phrase "local zone of protection", why is this in quotes? Is there a narrow definition for this? If so, this term should be defined also. DATA RETENTION SECTION 1.3 Regarding the data retention for Req. R3 and R4, it is not practical to keep potentially 24 years of data for components that are maintained every 12 years. We suggest rewording this to "For R3 and R4, Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the most recent performances of each distinct maintenance activity for the Protection System components, or to the previous scheduled audit date, whichever is longer". ATTACHMENT A – FOOTNOTE 1 This footnote regarding countable events needs to be revised to match the definition of countable events found at the beginning of the standard.

Yes
The tables rely on a reference document which is not a part of the standard and as such may be altered without due process. Either the relevant text from the reference needs to be inserted into the standard or the reference itself incorporated into the standard. Specific References such as
Yes
The supplemental reference provides significant clarity to the intent and application of standard; however, in doing so, it reveals conflicts and ambiguity in the text of the standard. It is suggested that some of the clarifying language be inserted into the text of the standard.
No Comment
Yes
The concept of including definitions in this standard that are not a part of the Glossary of Terms will create a conflict with other standards that choose to use the term with a different meaning. This practice should be disallowed. If a definition is be introduced it should be added to the Glossary of Terms. This concept was not provided to industry for comment when the modificatios to the Definition of Protection System was introduced. Additional related to this practice are included later on. The Term "Protective Relays" is overly broad as it is not limited to those devices which are used to protect the BES. In the reference provided to the standard, the SDT definied "Protective Relays" as "These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted portion of the BES. " The Definition for "Protective Relays" as well as the components associated with the them should be associated with the protection of the BES in the definition. The Section 2.4 of the attached reference and the recent FERC NOPR are in conflict with the definition of "Protective Relays" which include lockout relays and transfer trip relays "The relays to which this standard applies are those relays that use measurements of voltage, current, frequency and/or phase angle and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This Draft 2: April3: November 17, 2010 Page 5 definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals

from the current and voltage sensing devices." The definition should be revised to relfect that is really intended. The SDT as created an implied definition by specifically defining DC circuits associated with the trip function of a "Protective Relay" but failing to specifically define voltage and current sensing circuits providing inputs to "Protective Relays". The team clearly intended the circuits to be included but the definition does not since it only refers the the "voltage and current sensing devices". Starting with the Definitions and continuing through the end of the document, terms that have been defined are not capitalized. This leaves it ambiguous as to whether the defined term is to be applied or it is a generic reference. Only defined terms "Protection System Maintenance Program" and "Protection System" are consistently capitalized. Protection System Maintenance Program (PSMP) definition: The Restore bullet should be revised to read as follows: "Return malfunctioning components to proper operation by repair or calibration during performance of the initial on-site activity." Add the following at the end of the PSMP definition: “NOTE: Repair or replacement of malfunctioning Components that require follow-up action fall outside of the PSMP, and are considered Maintenance Correctable Issues.” Protection System (modification) definition: The term "protective functions" that is used herein should be changed to "protective relay functions" or what is meant by the phrase should become a defined term, as it is being used as if it is a well known well defined, and agreed upon term. The first bullet text should be revised to read as follows: "Protective relays that monitor BES electrical quantities and respond when those quantities exceed established parameters," the last two bullets should be reversed in order and modified to read as follows: • control circuitry associated with protective relay functions through the trip coil(s) of the circuit breakers or other interrupting devices, and • station dc supply (including station batteries, battery chargers, and non-battery-based dc supply) associated with the preceding four bullets. Statement between the Protection System (modification) definition and the Maintenance Correctable Issue definition; Is this a NERC accepted practice? There does not appear to be a location in the standard for defining terms. Having terms that are not contained in the "Glossary of Terms used in NERC Reliability Standards," and are outside of the terms of the standards, and yet are necessary to understand the terms of the Requirements is not acceptable. They would become similar to the reference documents, and could be changed without notice. Maintenance Correctable Issue definition: The last sentence should be modified to read as follows: "Therefore this issue requires follow-up corrective action which is outside the scope of the Protection System Maintenance Program and the Standard PRC-005-2 defined Maximum Maintenance Intervals." The definition could also be easily clarified to read "Maintenance Correctable Issue – Failure of a component to operate within design parameters such that it cannot be restored to functional order by repair or calibration; therefore requires replacement." This ensures that any action to restore the equipment, short of replacement, is still considered maintenance. Otherwise ambiguity is introduced as what "maintenance" is. Countable Event definition: An explanation should be made that this is a part of the technical justification for the ongoing use of a performance-based Protection System Maintenance Program for PRC-005. Insert the phrase "Standard PRC-005-2" before the term "Tables 1-1…" 4. Applicability: 4.2. Facilities: 4.2.5.4 and 4.2.5.5: Delete these two parts of the applicability. Station service transformer protection systems are not designed to provide protection for the BES. Per PRC-005-2 Protection System Maintenance Draft Supplementary Reference, Nov. 17 2010, Section 2.3 - Applicability of New Protection System Maintenance Standards: “The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005: “...affecting the reliability of the Bulk Electric System (BES)…” To the present language: “… and that are applied on, or are designed to provide protection for the BES.” The drafting team intends that this Standard will not apply to “merely possible” parallel paths, (sub-transmission and distribution circuits), but rather the standard applies to any Protection System that is designed to detect a fault on the BES and take action in response to that fault.” Station Service transformer protection is designed to detect a fault on equipment internal to a powerplant and not directly related to the BES. In addition, many Station Service protection ensures fail over to a second source in case of a problem. Thus station service transformer protection system is a powerplant reliability issue and not a BES reliability issue. As such station service transformer protection should not be included in PRC 005 2. In addition, the SDT appears to have targeted generation station service without regard to transmission systems. If generating station service transformers are that important, then why are substation/switchyard station service transformers not also important? B. Requirements Should the sub requirements have the "R" prefix? R4. Change the phrase "… PSMP, including identification of the resolution of all …" to read "…PSMP including identification, but not the resolution, of all …". General comment PRC005-2 is very specific in listing the maximum maintenance interval but is still very vague in listing the specific components to test. Suggest adding the following to the standard. A

sample list of devices or systems that must be verified in a generator to meet the requirements of this Maintenance Standard: Examples of typical devices and relay systems that respond to electrical quantities and may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to: • Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions • Loss-of-field relays • Volts-per-hertz relays • Negative sequence overcurrent relays • Over voltage and under voltage protection relays • Stator-ground relays • Communications-based protection systems such as transfer-trip systems • Generator differential relays • Reverse power relays • Frequency relays • Out-of-step relays • Inadvertent energization protection • Breaker failure protection • lockout or tripping relays For generator step up transformers, operation of any the following associated protective relays frequently would result in a trip of the generating unit and, as such, would be included in the program: • Transformer differential relays • Neutral overcurrent relay • Phase overcurrent relays In the Lower, Moderate and Severe VSL descriptions, in addition to not being capitalized, the defined term Maintenance Correctable Issues should not be hyphenated. In Attachment A Section 2 Page 51 should be modified as follows: 2. Maintain the components in each segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5 until results of maintenance activities for the segment are available for a minimum of either 30 individual components of the segment or a significant statistical population of the individual components of a segment." Without the modifiction the requirement unfairly target smaller entities. This will allow smaller entities to determine adjust its time based intervals if its experience with an appropriate number components supports it. In Attachment A Section 5 Page 51 should be modified as follows: 5. Determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or a significant statistical population of the individual components of a segment maintained in the previous year. Without the modifiction the requirement unfairly target smaller entities. This will allow smaller entities to determine adjust its time based intervals if its experience with an appropriate number components supports it. In Attachment A Section 5 Page 52 should be modified as follows: 5. Using the prior year's data, determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or a significant statistical population of the individual components of a segment components maintained in the previous year. Without the modifiction the requirement unfairly target smaller entities. This will allow smaller entities to determine adjust its time based intervals if its experience with an appropriate number components supports it.

Yes
The Requirement R1.5. is vague and the intent is not well understood. We recommend it be rewritten to clarify the intent. In the Requirement R2. the phrase "... shall verify those components possess the monitoring attributes ..." is too vague and not easily understandable. We recommend this requirement be rewritten.

No

No
Yes
In the Purpose statement delete “affecting” and replace it with “protecting”. The purpose of the standard deals with systems that protect the BES. In sections R1 and R4.2.1 delete “applied on” as unneeded and potentially confusing. The goal is to cover Protection Systems designed to protect the BES. Alliant Energy believes that Article 1.4 needs to be deleted from the standard. It is redundant and serves no purpose. Alliant Energy believes that Article 1.5 needs to be deleted from the standard. There is a major concern on what an “acceptable parameter” is and how it would be interpreted by the Regional Entities. Section 4.2 Applicable Facilities: We are concerned with this paragraph being interpreted differently by the various regions and thereby causing a large increase in scope for Distribution Provider protection systems beyond the reach of UFLS or UVLS. 4.2.1 Protection Systems applied on, or designed to provide protection for, the BES. The description is vague and open for different interpretations for what is “applied on” or “designed to provide protection”. According to the November 17, 2010 Draft Supplementary Reference page 4, the Standard will not apply to sub-transmission and distribution circuits, but will apply to any Protection System that is designed to detect a fault on the BES and take action in response to the fault. The Standard Drafting Team does not feel that Protection Systems designed to protect distribution substation equipment are included in the scope of this standard; however, this will be impacted by the Regional Entity interpretations of ‘protecting” the BES. Most distribution protection systems will not react to a fault on the BES, but are caught up in the interpretation due to tripping a breaker(s) on the BES. We request clarification that the examples listed below do not constitute components of a BES Protection System: 1. Older distribution substations that lack a transformer high side interrupting device and therefore trip a transmission breaker or a portion of the transmission system or bus, or 2. Newer distribution substations that contain a transformer high side interrupting device but also incorporate breaker failure protection that will trip a transmission breaker or a portion of the transmission system or bus. Since distribution provider systems are typically radial and do not contain the level of redundancy of transmission or generation protection systems, it is not cheap, safe, maintaining BES reliability, or easy to coordinate companies to test these protection systems to the level of PRC-005-2 draft recommendations. Section F Supplemental Reference Documents: The references listed in this section refer to 2009 dates and do not match with the 2010 reference documents supplied for comment. Table 1-4 Component Type Station dc Supply: • “Any dc supply for a UFLS or UVLS system” - This should not have the same testing interval as control circuits, but should have a maximum maintenance period as other dc supplies do. • Replace the words “perform as designed” on page 14 of Table 1-4 with “operate within defined tolerances.” Table 1-5 Component Type Control Circuitry: • This table allows for unmonitored trip coils for UFLS or UVLS breakers to have “no periodic maintenance”. The PRC-005-2 Supplemental Frequently Asked Question #7B and #7C give excellent reasoning for not requiring maintenance on the trip coil component due to the larger number of failures that would be required to have any substantial impact to the BES as well as the statement that distribution breakers are operated often on just fault clearing duty already. We believe that the unmonitored control circuitry has the same level of minimal BES impact and is also being tested each time the distribution breaker undergoes fault clearing duty. With this logic, we do not see why there would be different maintenance requirements for these two components. • Alliant Energy is concerned that the addition of mandatory 86 and 94 auxiliary lockout relays (Electromechanical trip or Auxiliary devices) will force entire bus outages that will compromise the BES reliability more by forcing utilities across the US to unnecessarily take multiple non-faulted BES elements out of service. Such testing is also likely to introduce human error that will cause outages such as items outlined in the NERC lessons learned” and therefore such testing will result in more outages than actual failures. An equivalent non-destructive test needs to be identified to allow entities to sufficiently trace and test trip paths without taking multiple substation line outages to physically test a lockout or breaker failure scheme.

UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuitry, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection, the Applicability section should. For instance, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical Table 1-4 requires a comparison of measured battery internal ohmic value to battery baseline. Battery manufacturers typically do not provide this value and one manufacturer states that the baseline test are to be performed after the battery has been in regular float service for 90 days. It is unclear how to comply with the requirement for the initial 90 days. Additionally, we would recommend that this requirement be modified to permit an entity to establish a “baseline” value based on statistical analysis of multiple test results specific to a given battery manufacturer/model. Several commenters previously expressed their concerns with performing capacity tests. While this may just be an entity’s preference, allowing an entity to establish a baseline at some point beyond the initial installation period would give entities the option of using the internal resistance test in lieu of a capacity test.

Small entities with only one or two BES substations may not have enough components to take advantage of the expanded maintenance intervals afforded by a performance-based maintenance program. Aggregating these components across different entities doesn't seem too logical considering the variations at the sub-component level (wire gauge, installation conditions, etc.) Trip circuits are interconnected to perform various functions. Testing a trip path may involve disabling other features (i.e. breaker failure or reclosing) not directly a part of the test being performed. Temporary modifications made for testing introduce a chance to accidentally leave functions disabled, contacts shorted, jumpers lifted, etc. after testing has been completed. Trip coils and cable runs from panels to breaker can be made to meet the requirements for monitored components. The only portions of the circuitry where this may not be the case is in the inter- and intra-panel wiring. Because such portions of the circuitry have no moving parts and are located inside a control house, the exposure is negligible and should not be covered by the requirements. Entities will be at increased compliance risk as they struggle to properly document the testing of all parallel tripping paths. The interconnected nature of tripping circuits will make it difficult to count the number of circuits consistently for the purpose of calculating a VSL.

It would help to add a column to the left labeled Category. I.E. a relay could be classified under Category 1 attributes unmonitored or Cat 2, Cat 3. Table 1-4, Station DC is very difficult to follow.
Yes
Yes
Well written and helpful document. In Section 8.1, the document states that if your PSMP requires activities more often than the Tables maximum, then you must perform to that higher standard. While it is understandable that an entity may desire to maintain their PRS at a higher level, they should not be fined or penalized for achieving less than their standard but within the intervals stated in the Tables. This point should be clarified, preferably within the standard itself.

Figure 2 “typical generation system” shows a typical auxiliary medium voltage bus, in addition to the color coded elements suggest that a very distinct line of demarcation (dark dotted line) be added to the figure that defines the elements associated with the MV bus protection served by the station Aux Transformer and unit aux transformer are not part of the BES- PSMP PRC5 requirements. Also see comment 5 below; we suggest that the station service transformer must be connected to BES for inclusion in standard requirements. Suggest adding an explanation note to figure 2 to clarify this.
Yes
Suggest that the section 5 – station DC supply have some specific examples added that would be acceptable methods for verifying the “state of charge” as required by standard table 1-4.
Yes
The facilities listed in 4.2.5.5 include protection systems for “system connected” station service transformers associated with generators that are part of the BES. If a station service transformer is connected to a non BES bus then it would still fall under the PRC5 applicability requirements as

written. The FAQs discuss relays associated with station auxiliary loads as not included in the program requirements. The non BES connected transformers should be included in that same category of equipment. From the FAQ's - "Relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of the those loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program even if a trip of these devices might eventually result in a trip of the generating unit." Suggest the following added details be considered to be consistent with intent of BES connected facilities. Revise Description 4.2.5.5 as follows: "Protection systems for BES system connected station service transformers connected for generators that are part of the BES". With respect to DC supply systems (batteries, chargers),the implementation plan is too aggressive. Some battery checks will have to be done on a 3 month interval, and entities will be required to be compliant with this new frequency in 1 Calendar year. This timeframe is unreasonable and needs to be pushed back to at least 2 years. PSEG is also asking for clarification to the supplemental reference document: On page 4, section 2.3 it states that the standard is designed to ONLY include "relays that detect a fault on the BES and take action in response to that fault". If PSEG is interpreting this correctly, this is a massive shift from the existing PRC-005-1 standard. The existing PRC-005-1 includes all distribution relays that trip a BES breaker to be part of the scope. In this revision, PRC-005-2 would exclude those distribution relays if they are designed to act for faults on the distribution system. PSEG would fully support this interpretation. PSEG would like this clarified and confirmed. This is very important.

The Standard Drafting Team should be commended for making the tables much easier to understand
No
We disagree with the inclusion of the VSLs, VRFs, and time Horizons associated with the new Requirements 1.5 and 4.2
Yes
Page 11 and 12, (Additional Notes for Table 1-1 through 1-5) Comment ->> The standard does not reference these notes. Should these notes be referenced and included in the Standard? Page 12, Additional Notes for Table 1, item #7 ("performing an operational trip test") Comment ->> Standard does not state that an operational/full functional test is required. Please clarify. Page 22, 15.3, Control Circuitry Functions, paragraph 1 ("verify, with a volt-meter, the existence of proper voltage at the open contacts") Comment ->> The example of measuring the proper voltage with a volt-meter at the open contacts to verify the circuit indicates that the 12-year "full functional" trip test of control circuits is not required. Please clarify. Page 22, 15.3, Control Circuitry Functions, paragraph 3 ("UVLS or UFLS scheme are excluded from the tripping requirement, but not from the circuit test requirements") Comment ->> This indicates to me that measuring the proper voltage with a volt-meter at the open contacts will verify the circuit. Please confirm. Please clarify – If a suitable monitoring system is installed that verifies every parallel trip path then the manual-intervention testing of those parallel trip paths can be "extended beyond 12 years". Standard indicates that no periodic maintenance is required. Consider changing "extended beyond 12 years" to "eliminated". Page 23, 15.3, Control Circuitry Functions, paragraph 5 ("When verifying the operation of the 94 and 86 relays each normally-open contact that closes to pass a trip signal must be verified as operating correctly.") Comment ->> This indicates that we must verify that trip and auxiliary device contacts change state. Please confirm. The standard does not state that the contacts must be verified to change states. If this is required, please add to the standard.
Yes
Page 7, L. ("verify operation of the relay inputs …") Comment ->> Clarification needed. Standard states that each input should be "picked up" or "turned on and off". Do you have to change states of the input contact(s) or can you just jumper positive to the input(s) to verify that the microprocessor relay verifies this change of state? Page 10, 4.E ("What does functional (or operational) trip test include?") Comment ->> The words "functional (or operational) trip test" are not in the Standard. Is this required? If so, please clarify this in Standard. If not, please remove. (Reference comment

regarding “verify all paths of the control and trip circuits” on page 17 of standard.) Page 18, 7. (Distributed UVLS and UFLS system.) and Page 19 8. (Centralized UVLS and UFLS system.) Comment ->> Standard does not specify “distributed” or “centralized” UVLS and UFLS systems. Please consider combining section 7 & 8, omitting items 7.C., 8.E., and omitting “distributed” and “centralized” references on pages 18 and 19.
Yes
Page 5, 4.2. (“or initiate resolution”) Comment ->> Standard does not specify to “follow through” to completion. Is record of completion required? Page 5, 1.5. (1.5. Identify calibration tolerances or other equivalent parameters for each Protection System component type that establish acceptable parameters for the conclusion of maintenance activities.) Comment ->> This is too vague, broad, general and all encompassing. For example, what is the calibration tolerance for “control circuitry” which is made up of many things such as wiring, auxiliary relays, trip coils, etc. We currently have calibration tolerances on electromechanical relays but not on all components of a protection system (communications systems, voltage and current sensing devices, station dc supply, control circuitry). To try to identify calibration tolerances or other equivalent parameters for each of these components would be extremely difficult and time consuming. Clarification is needed on what components or parts of components require calibration tolerances. Another option is to remove this requirement. Page 5, 4.5. (4.2. Either verify that the components are within the acceptable parameters established in accordance with Requirement R1, Part 1.5 at the conclusion of the maintenance activities, or initiate resolution of any identified maintenance correctable issues.) Comment ->> See comments above on 1.5. Clarification is needed on what is required to verify that the components are within acceptable parameters. We feel it should be adequate to provide a simple way to verify this requirement such as to include this in our maintenance procedure (equipment is to be left within tolerance), provide closed work order, show “checked” check box, provide a simple statement that this was completed, or etc. We feel that having to provide detailed data such as “as found” / “as left” values is too complicated and time consuming. Please clarify or consider removing this requirement. Page 6, M.4. (“and initiated resolution”) Comment ->> Standard does not specify to “follow through” to completion. Is record of completion required? Page 10, F.1 (July 2009) & F.2 (DRAFT 1.0 - June 2009) Comment ->> Need new dates and draft number. Page 11 (For microprocessor relays, verify operation of the relay inputs and outputs that are essential …) Comment ->> Does this require changing the state of the input contacts or can you just jumper voltage to the inputs and verify that the microprocessor relays acknowledged the change? Page 17 (“Verify electrical operation(1)of EM trip and auxiliary devices(2).”) Comment ->> (1) Is it required to verify that trip and auxiliary device contacts change state? If so, please state as a requirement. (2) We recommend that this requirement only includes EM aux LO / tripping relays that trip interrupting devices directly. Other EM aux relays such as BFI aux. relays should be excluded. Please state this clearly in the Standard. Note that these aux relays such as BFI aux relays are included in the “unmonitored control circuitry associated with protective functions” requirement and will be verified on a 12 year interval. (3) Please consider including an elementary diagram to show what is included. Page 17 (Verify all paths of the control and trip circuits.) Comment ->> Clarification needed. Is it required to perform a full functional test, i.e. trip breakers? Or is reading DC across trip contacts all that is required? Page 14 (Table 1.4) Change the maintenance interval for unmonitored station dc supply from “3 Calendar Months” to “4 times Annually”. This facilitate compliance to the standard by creating completion milestones for batteries at the end of each quarter of the year. Page 15 (Table 1.4 The standard requires the establishment of a battery baseline for cell/unit internal ohmic values and the comparison of impedance readings every 18 calendar months to that baseline. Due to the lack of original impedance readings at the time of installation of the battery. Since in many cases no such data is available; it needs to be made clear that establishing a baseline from , from manufacturer’s data, the most recent impedance test, or the first impedance test completed after the adoption of the new standard is acceptable

MidAmerican Energy
Yes
Yes

Yes
The Supplementary Reference should have clear disclaimers indicating that nothing in the reference is mandatory and enforceable.
Yes
The Frequently Asked Questions should have clear disclaimers indicating that nothing in the reference is mandatory and enforceable.
Yes
MidAmerican remains concerned that including requirements for testing of electromechanical trip or auxiliary devices (Table 1-5 Row 3) will in some cases require entire bus outages that will compromise the BES reliability due to the need for entities across the US to take multiple BES elements out of service during the testing. If this requirement is retained additional time should be included in the implementation plan to allow for system modifications, such as the installation of relay test switches, to potentially allow for this testing while minimizing testing outages. Clarify that in the definition of Component Type that Transmission Owners are allowed the latitude to designate their own definitions for each of the Component Types, not just control circuits. In the implementation schedule time periods are provided within which compliance deadlines and percentages of compliance are given. The following clarifications are recommended: 1. In calculating percentage of compliance for purposes of demonstrating progress on the implementation plan the percentages are calculated based on the total population of the protection system components that an entity has that fit the component category and allowable interval. 2. To obtain compliance with the percentage completion requirements of the implementation schedule an entity needs to have completed at least one prescribed maintenance activity of that component type and interval. In the purpose statement delete “affecting” and replace it with “protecting”. The purpose of the standard deals with systems that protect the BES. In sections R1 and R4.2.1 delete “applied on or” as unneeded and potentially confusing. The goal is to cover protection systems designed to protect. Clarify the meaning of “state of charge” on page 14 in Table 1-4. In Table 1-4 Component Type Station dc Supply, “Any dc supply for a UFLS or UVLS system” should have the same maximum maintenance period as other dc supplies. Table 1-5 Component Type Control Circuitry, the table allows for unmonitored trip coils for UFLS or UVLS breakers to have “no periodic maintenance”. The PRC-005-2 Supplemental Frequently Asked Question #7B and #7C give excellent reasoning for not requiring maintenance on the trip coil component due to the larger number of failures that would be required to have any substantial impact to the BES as well as the statement that distribution breakers are operated often on just fault clearing duty already. We believe that the unmonitored control circuitry has the same level of minimal BES impact and is also being tested each time the distribution breaker undergoes fault clearing duty. With this logic, we do not see why there would be different maintenance requirements for these two components.

Kirit Shah
Ameren
Yes
No
(1)The Lower VSL for all Requirements should begin above 1% of the components. For example for R4: “Entity has failed to complete scheduled program on 1% to 5% of total Protection System components.” PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability in that valuable resources will be distracted from other duties.
No
No
This document is helpful.
Yes
(1)We believe that R1.5 and R4.2 “Calibration tolerances or other equivalent parameters”

requirements should be removed. Neither the Supplement nor the FAQ address the expectation for them. While we agree that tolerances are needed and used, they need not be specified as part of this standard. (2) The Data retention is too onerous (a) For those components with numerous cycles between on-site audits, retaining and providing evidence of the two most recent distinct maintenance performances and the date of the others should be sufficient. Additionally, we are subject to self-certification, spot audits and/or inquiries at any time between on-site audits as well. (b) For those components with cycles exceeding on-site audit interval, retaining and providing evidence of the most recent distinct maintenance performance and the date of the preceding one should be sufficient. Auditors will have reviewed the preceding maintenance record. Retaining these additional records consumes resources with no reliability gain. (3) Definition of the BES perimeter should be included in accordance with Project 2009-17 Interpretation. (a)Facilities Section 4.2.1 “or designed to provide protection for the BES” needs to be clarified so that it incorporates the latest Project 2009-17 interpretation. The industry has deliberated and reached a conclusion that provides a meaningful and appropriate border for the transmission Protection System; this needs to be acknowledged in PRC-005-2 and carried forward. (4)System-cnnected station service transformers (4.2.5.5)should be ommited, because (a) Generating Plant system-connected Station Service transformers should not be included as a Facility because they are serving load. Omit 4.2.5.5 from the standard. There is no difference between a station service transformer and a transformer serving load on the distribution system. This has no impact on the BES, which is defined as the system greater than 100 kV. (b) system-connected station service transformers in the same table as well as from table-to-table can be overwhelming. This would help keep Regional Entities and System Owners from making errors. (5) Retention of maintenance records for replaced equipment should be ommitted. FAQ II 2B final sentence states that documentation for replaced equipment must be retained to prove the interval of its maintenance. We disagree with this because the replaced equipment is gone and has no impact on BES reliability; and such retention clutters the data base and could cause confusion. For example, it could result in saving lead acid battery load test data beyond the life of its replacement. (6) Battery inspection every 4 months is sufficient. IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months due to storms and outages must set a target interval of two months thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, we also suggest that all intervals expressed as 3 calendar months be changed to 4 calendar months. (7) PSMP Implement Date should commence at the beginning of a Calendar year. This is the most practical way to transition assets from our existing PRC-005-1 plans. (8) Please clarify the meaning of “state of charge” for batteries. Does this mean specific gravity testing or what? (9) Please clarify that instrument transformer itself is excluded. Please clarify that the instrument transformer itself is excluded. The standard indicates that only voltage and current signals need to be verified in Table 1-3, but the recently approved Protection System definition wording can be mis-interpreted to mean they are included. FAQ 11.3.A is helpful.

Yes
Yes
No
No
Yes
In the Purpose statement delete “affecting” and replace it with “protecting”. The purpose of the standard deals with systems that protect the BES. In sections R1 and R4.2.1 delete “applied on” as unneeded and potentially confusing. The goal is to cover Protection Systems designed to protect the BES. The NSRS believes that Article 1.4 needs to be deleted from the standard. It is redundant and

serves not purpose. The NSRS believes that Article 1.5 needs to be deleted from the standard. There is a major concern on what an “acceptable parameter” is and how it would be interpreted by the Regional Entities. The NSRS believes that Article 4.2 needs to be deleted from the standard. There is no need for this article if Article 1.5 is deleted. Section 4.2 Applicable Facilities: We are concerned with this paragraph being interpreted differently by the various regions and thereby causing a large increase in scope for Distribution Provider protection systems beyond the reach of UFLS or UVLS. 4.2.1 Protection Systems applied on, or designed to provide protection for, the BES. The description is vague and open for different interpretations for what is “applied on” or “designed to provide protection”. According to the November 17, 2010 Draft Supplementary Reference page 4, the Standard will not apply to sub-transmission and distribution circuits, but will apply to any Protection System that is designed to detect a fault on the BES and take action in response to the fault. The Standard Drafting Team does not feel that Protection Systems designed to protect distribution substation equipment are included in the scope of this standard; however, this will be impacted by the Regional Entity interpretations of ‘protecting” the BES. Most distribution protection systems will not react to a fault on the BES, but are caught up in the interpretation due to tripping a breaker(s) on the BES. Section F Supplemental Reference Documents: The references listed in this section refer to 2009 dates and do not match with the 2010 reference documents supplied for comment. Table 1-4 Component Type Station dc Supply: • “Any dc supply for a UFLS or UVLS system” - This should not tied to the same testing interval as control circuits. The dc supply system is significantly different from control circuits and should have a maximum maintenance period as other dc supplies do. • Replace the words “perform as designed” on page 14 of Table 1-4 with “operate within defined tolerances.” Table 1-5 Component Type Control Circuitry: • This table allows for unmonitored trip coils for UFLS or UVLS breakers to have “no periodic maintenance”. “Unmonitored control circuitry associated with protective functions” should also have an exclusion for UFLS and UVLS circuitry that would allow for “no periodic maintenance”. • There is a concern that requiring the electrical testing and maintenance of Electromechanical trip or Auxiliary devices will force entire bus outages to be scheduled, which will compromise the BES reliability more by forcing utilities across the US to unnecessarily take multiple non-faulted BES elements out of service. Such testing is also likely to introduce human error that will cause outages such as items outlined in the NERC lessons learned” and therefore such testing will result in more outages than actual failures.

Consideration of Comments on Initial Ballot — Protection System Maintenance and Testing (Project 2007-17)
Date of Initial Ballot: December 10 – 20, 2010

Summary Consideration: Many commenters opposed R1 part 1.5 and the associated text, and the SDT responded by removing this text. Most of these comments were duplicates of those submitted in response to the formal comment period; the SDT responses are duplicated as well. Please see the Summary Consideration for each of the posted questions within the Consideration of Comments.

If you feel that the drafting team overlooked your comments, please let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Gerry Adamski, at 609-452-8060 or at gerry.adamski@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Voter	Entity	Segment	Vote	Comment
Rodney Phillips	Allegheny Power	1	Negative	Allegheny Power applauds the hard work that the Standards Draft Team has exhibited in producing a clear and enforceable standard that will increase the reliability of the Bulk Electric System. However, the addition of requirement 1.5 is such a significant change in scope from the last draft that a further review of the potential impact and any implementation concerns is required by AP and the industry in general before we can consider voting in-favor of this standard.
Response: **Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Kirit S. Shah	Ameren Services	1	Negative	(1)We believe that R1.5 and R4.2 “Calibration tolerances or other equivalent parameters” requirements should be removed. Neither the Supplement nor the FAQ address the expectation for them. While we agree that tolerances are needed and used, they need not be specified as part of this standard. (2)
Response: **Thank you for your comments. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Paul B. Johnson	American Electric Power	1	Negative	Restructured Tables: 1) Table 1.5 (Control Circuitry), row 4, indicates a maximum interval of 12 years for unmonitored control circuitry, yet other portions of control circuitry have a maximum interval of 6 years. AEP does not understand the rationale for the difference in intervals, when in most cases, one verifies the other. Also, unmonitored control circuitry is capitalized in row 4 such that it infers a defined term. 2) In the first row of table 1-4 on page 16, it is difficult to determine if it is a cell that wraps from the previous page or is a unique row. This is important

[1] The appeals process is in the Reliability Standards Development Procedure: http://www.nerc.com/files/RSDP_V6_1_12Mar07.pdf.

Voter	Entity	Segment	Vote	Comment
				because the Maximum Maintenance Intervals are different (i.e. 18 months vs 6 years). It is difficult to determine to which elements the 6 year Maximum Maintenance Interval applies. AEP suggests repeating the heading "Monitored Station dc supply (excluding UFLS and UVLS) with: Monitor and alarm for variations from defined levels (See Table 2):" for the bullet points on this page. VSLs, VRFs and Time Horizons: 3) The VSL table should be revised to remove the reference to the Standard Requirement 1.5 in the R1 "High" VSL. 4) All four levels of the VSL for R2 make reference to a "condition-based PSMP." However, nowhere in the standard is the term "condition-based" used in reference to defining ones PSMP. The VSL for R2 should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term "condition-based" within the Standard Requirements and Table 1. 5) In multiple instances, Table 1 uses the phrase "No periodic maintenance specified" for the Maximum Maintenance Interval. Is this intended to imply that a component with the designated attributes is not required to have any periodic maintenance? If so, the wording should more clearly state "No periodic maintenance required" or perhaps "Maintain per manufacturers recommendations." Failure to clearly state the maintenance requirement for these components leaves room for interpretation on whether a Registered Entity has a maintenance and testing program for devices where the Standard has not specified a periodic maintenance interval and the manufacturer states that no maintenance is required. FAQ and Supplementary Reference: 6) With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications: a) Section 5 of the Supplementary Reference, refers to "condition-based" maintenance programs. However, nowhere in the standard is the term "condition-based" used in reference to defining ones PSMP. The Supplementary Reference should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term "condition-based" within the Standard Requirements and Table 1.

Voter	Entity	Segment	Vote	Comment
				b) Section 15.7, page 26, appears to have a typographical error "…can all be used as the primary action is the maintenance activity…" c) Figure 2 is difficult to read. The figure is grainy and the colors representing the groups are similar enough that it is hard to distinguish between groups. 7) "Frequently-Asked Questions": With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications: a) The section "Terms Used in PRC-005-2" is blank and should be removed as it adds no value. b) Section I.1 and Section IV.3.G reference "condition-based" maintenance programs. However, nowhere in the standard is the term "condition-based" used in reference to defining ones PSMP. The FAQ should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term "condition-based" within the Standard Requirements and Table 1. c) The second sentence to the response in Section I.1 appears to have a typographical error "… an entity needs to and perform ONLY time-based…". 8) General: a) Standards Requirement 1.5 and the reference to R1.5 in Requirement 4.2 should be removed. Specifying calibration tolerances for every protection system component type, while a seemingly good idea, represents a substantial change in the direction of the standard. It would be very onerous for companies to maintain a list of calibration tolerances for every protection system component type and show evidence of such at an audit. AEP believes entities need the flexibility to determine what acceptance criteria is warranted and need discretion to apply real-time engineering/technician judgment where appropriate. b) Three different types of maintenance programs (time-based, performance-based and condition-based) are referenced in the standard or VSLs, yet the time-based and condition-based programs are neither defined nor described. Certain terms defined within the definition section (such as Countable Event or Segment) only make sense knowing what those three programs entail. These programs should be described within the standard itself and not assume a knowledge of material in the Supplementary

Voter	Entity	Segment	Vote	Comment
				Reference or FAQ. c) “Protective relay” should be a defined term that lists relay function for applicability. There are numerous ‘relays’ used in protection and control schemes that could be lumped in and be erroneously included as part of a Protection System. For example, reclosing or synchronizing relays respond to voltage and hence could be viewed by an auditor as protective relays, but they in fact perform traditional control functions versus traditional protective functions.

Response: Thank you for your comments.

1. The 6-year activities are all related to components with “moving parts”, and the 12-year activities are related to the other portions of the control circuitry. The capitalized term has been corrected.
2. Table 1-4 has been modified in consideration of your comments.
3. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised.
4. The SDT concluded that Requirement R2 is redundant with R1, Part 1.4, and has deleted R2 (together with the associated Measure and VSL).
5. If the indicated monitoring attributes are present, no “hands-on” periodic maintenance is required, as the monitoring of the component is providing a continuing indication of its functionality.
6. The discussion within the Supplementary Reference and FAQ are informative, not normative, and thus do not belong as part of the standard.
   A. The Supplemental Reference Document discusses condition-based maintenance in a conceptual manner, as a generally-recognized term. The SDT did make some changes within the Supplemental Reference document to clarify the manner in which condition-based maintenance is discussed.
   B. This clause has been corrected.
   C. A higher-quality version of Figure 2 has been substituted.
7. The discussion within the Supplementary Reference and FAQ are informative, not normative, and thus do not belong as part of the standard.

a) The SDT decided to eliminate the FAQ document and incorporate the FAQ’s contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.
b) The SDT decided to eliminate the FAQ document and incorporate the FAQ’s contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.
c) The SDT decided to eliminate the FAQ document and incorporate the FAQ’s contents into the Supplementary Reference

Voter	Entity	Segment	Vote	Comment
Document as appropriate. The SDT considered your comments during this activity. 8. A) The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. B) The term, "condition-based" has been removed from the draft standard. The other terms are used, but are clear in the context in which they are used. C) "Protective relay" is defined by IEEE, and the SDT sees no need to either change the definition or to repeat the definition with PRC-005. Further, the applicability of generically-described protective relays is defined by the Applicability clause of PRC-005-2.				
Jason Shaver	American Transmission Company, LLC	1	Negative	ATC recognizes the substantial efforts that the SDT has made on PRC-005 and appreciate the SDT's modifications to this Standard based on previous comments made. ATC looks forward to continuing to have a positive influence on this process via the comment process, ballots and interaction with the SDT. ATC was very close to an affirmative vote on this Standard prior to the unanticipated changes that appeared in this most recent posting. These changes introduce a significant negative impact from ATC's perspective. Therefore, ATC is recommending a negative ballot in the hope that our concerns regarding R 1.5 and R 4.2 and other clarifications will be included with the standard.
1. **Response**: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.				
John Bussman	Associated Electric Cooperative, Inc.	1	Negative	AECI want to thanks the team for the efforts being put forth by the drafting team. The table is much easier to follow and less confusing. AECI is voting negative because of the battery inspection intervals. 1. We have commented before about the 3 months being excessive and think it should be annually. However, with that being stated if you are going to use three months as the interval then that means inspections will have to be scheduled every 2 months to ensure the inspections happen every 3 months. Therefore AECI request that the battery inspection schedule be extended to every 4 months and then entities can schedule inspections to be performed every 3 months to ensure that the inspections are completed every 4 months.

Voter	Entity	Segment	Vote	Comment
				2. The same comment applies the the unmonitored communication circuits. Change the time interval to 4 months. Then scheduling can be every 3 months instead of every 2 months. 3. When you go to Table 1-4 there is confusion with the the DC for a UFLS or UVLS system. For the interval it states "When control circuits are verified" Then I go to Table 1-5 the second line that discusses trip coils for UFLS and UVLS the interval states "No periodic maintenance specified" Is this what was intended?
Response: **Thank you for your comments.** **1. The SDT believes that the 3-month interval is proper.** **2. The SDT believes that the 3-month interval is proper for unmonitored communications systems.** **3. The SDT intends that tripping of the interrupting device for UFLS/UVLS is not required, but that the other portions of the dc control circuitry still shall be maintained. See Section 15.3 of the Supplementary Reference Document**				
Joseph S. Stonecipher	Beaches Energy Services	1	Negative	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What we see as a problem is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves, in part, to ensure that the regionsl UFLS program is being met; but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution line breakers are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about nill. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that

Voter	Entity	Segment	Vote	Comment
				trips a BES Facility." 3. Applicability, 4.2. - does not reflect the interpretation of Project 2009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical.
Response: Thank you for your comments. 1. For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities related to the interrupting device trip coil. 2. This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1. in consideration of your comment. 3. The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.				
Donald S. Watkins	Bonneville Power Administration	1	Negative	Please see BPA's formal comments submitted on 12/16/10. Our concerns have not been adequately addressed.
Response: Thank you for your comments. Please see our responses to your comments from the formal comment period.				
Paul Rocha	CenterPoint Energy	1	Negative	1) CenterPoint Energy cannot support this proposed Standard. Any standard that requires a 35 page Supplementary Reference document and a 37 page FAQ - Practical Compliance and Implementation document is much too prescriptive and complex. 2) CenterPoint Energy is very concerned that a large increase in the amount of documentation will be required in order to demonstrate compliance - with no resulting reliability benefit. CenterPoint Energy believes this Standard could actually result in decreasing system reliability, as the Standard proposes excessive maintenance requirements. The following is included in the

Voter	Entity	Segment	Vote	Comment
				Supplementary Reference document (page 8): "Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it." System reliability can be even further reduced by the number of transmission line and autotransformer outages required to perform maintenance. 3) In addition, the following is included in the FAQ - Practical Compliance and Implementation document: "PRC-005-2 assumes that thorough commission testing was performed prior to a protection system being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components such that a properly built and commission tested Protection System will continue to function as designed over its service life." CenterPoint Energy believes some proposed requirements, such as wire checking a relay panel, do not conform to this statement. CenterPoint Energy's experience has been that panel wiring does not degrade with age and service and that problems with panel wiring, after thorough commissioning, is not a systemic issue.
Response: **Thank you for your comments.** **1. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate.** **2. FERC Order 693 directed that NERC establish maximum maintenance intervals. The documentation required should not expand dramatically from the documentation currently required to demonstrate compliance. An entity may minimize hands-on maintenance by utilizing monitoring to extend the intervals.** **3. The standard does not require "wire-checking," but instead generically specifies "verification" – however an entity chooses to do so.**				
Jack Stamper	Clark Public Utilities	1	Negative	My no vote reflects my concern regarding the testing of Station DC Supply (Table 1-4) and Alarming Paths (Table 2). The SDT has provided much clarity to this standard in the testing requirements for relays, communication systems, voltage and current sensing devices, and control circuitry. 1. Table 1-4 is still confusing. There are five separate categories of unmonitored Station DC Supply testing requirements. It is unclear whether these categories are to be combined or if they are mutually exclusive. The first category applies to "Any unmonitored station dc supply not having the monitoring attributes of a category below" and appears to be a set of inspection and verification

Voter	Entity	Segment	Vote	Comment
				requirements that are generally applicable to all unmonitored Station DC Supplies. The next four categories are applicable to Station DC Supply with specified types of batteries. If a station has unmonitored vented lead-acid batteries, are the batteries ONLY subject to the testing requirements for VLA batteries? OR would these batteries ALSO be subject to the requirements of the first category? It appears that the intent is for all Station DC Supply not having any monitoring attributes to be tested and maintained in accordance with the first category as well as the second through fifth category that is applicable. If this is the case, the SDT should consider revising the Component Attributes in Table 1-4 for the first category of Unmonitored Station DC Supplies to the following: Any unmonitored station dc supply not having the monitoring attributes of a category below. (excluding UFLS and UVLS). Station DC Supply devices applicable under these Table 1-4 general requirements will have additional testing requirements as described below for non-battery systems, VRLA battery systems, VLA battery systems, and Ni-Cad battery systems. 2. Do monitored batteries need to have all of the monitoring attributes listed or does having some of the monitoring attributes qualify a device as "Monitored?" The frequently asked questions examples on pages 30 - 32 seem to indicate that if only some of the items are monitored, the Station DC Supply is considered “Monitored” as long as other items are tested or verified. If this is the case, the SDT should consider revising the Component Attributes in Table 1-4 for the first category of Monitored Station DC Supplies to the following: Monitored Station dc supply (excluding UFLS and UVLS) with: Monitor and alarm for variations from defined levels (See Table 2): o Station dc supply voltage (voltage of battery charger) o State of charge of the individual battery cell/units o Battery continuity of station battery o Cell-to-cell (if available) and battery terminal resistance. Monitored Station dc supply will have one or more of the above listed conditions monitored or alarmed with the remainder of the conditions subject to inspection and verification activities. 3. In Table 2, the first Component Attribute for Alarm Paths contains the requirement that “Alarms are automatically reported within 24 hours of DETECTION to a location where corrective action can be taken.” I believe the term “automatically” should be removed. This term implies an automated process without human intervention. However, many facilities (i.e. generator

Voter	Entity	Segment	Vote	Comment
				protection devices or manned substations) have protective devices that while not being subject to continuous monitoring, are visually inspected in daily or twice daily inspections. If protection devices have internal self-diagnostics that provide an alarm (i.e. failure indication on faceplate, relay interrogation, or LED failure indicator) and these devices are inspected one or more times per day, failures or malfunctions would be reported within the 24 hour DETECTION time. This appears to be within the intent of the standard which is to make sure that failed protective devices do not remain in failure longer than 24 hours without notification to a location where corrective action can be taken.
Response: **Thank you for your comments.** **1. Table 1-4 has been modified in consideration of your comments.** **2. Table 1-4 has been modified in consideration of your comments, and has been revised to remove "state of charge".** **3. "Automatically" has been removed from Table 2 in consideration of your comment.**				
Danny McDaniel	Cleco Power LLC	1	Negative	Cleco applies its' UFLS on the distribution grid with each UF relay individually tripping a relatively low value of load thru breakers and reclosers. Since our program is implemented via a large number of individual components, breakers, reclosers, and individual batteries, the failure of any one component will have a minimal impact on the effectiveness of the overall UFLS program within our region. Therefore, the verification of sensing devices, dc supply voltages, and the paths of the control circuit and trip circuits on the UFLS systems implemented on the distribution grid is unnecessary.
Response: **Thank you for your comments. The SDT disagrees; the sensing devices, control circuitry and dc supply related to UFLS has an effect on the performance of the UFLS. The SDT has, however, respected the overall impact on the control circuitry of individual UFLS on BES reliability by requiring that UFLS be subjected to a subset of the overall sensing devices, control circuitry and dc supply maintenance activities.**				
Paul Morland	Colorado Springs Utilities	1	Negative	CSU offers the following comments: 1. The document refers to the "BES" or "Bulk Electrical System" yet we have been unable to get a clear definition as to what that is. 2. 1.5 Because some calibration tolerances, such as communications schemes, change with the weather conditions, establishing tolerances could be difficult if the weather conditions are not factored into the tables. 3. 4.2.5.4 There needs to be a clear definition for "Station Service Transformers". 4. The reference to testing tolerances implies that test equipment must be calibrated to some standard, which this document does not discuss, and leaves a very wide interpretation for what this standard is, or the required calibration is required. 5. Table 1-3 Voltage and current devices may be connected to a meter and compared to a reference source to verify proper operation of the CT or PT. This seems to be at error in thinking that only microprocessor relays can be

Voter	Entity	Segment	Vote	Comment
				used to verify CT or PT's. Also in many PT's there is more than one winding and tap, or which this standard seems to imply that only one needs to be monitored to verify the correct function of all of the windings and taps. If I were to follow this logic, I only need to monitor one winding of a dual core CT.
Response: Thank you for your comments. 1. Bulk Electric System is defined by NERC, and further defined by the Regional Entities. Please refer to these definitions. 2. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. 3. Station Service transformer provide power to the auxiliary busses of generating plants. Some alternative names for these devices are "unit auxiliary transformers", "station auxiliary transformers", The SDT believes that these devices are commonly understood throughout industry and therefore require no definition. 4. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. 5. Table 1-3 does not prescribe how the voltage and current sensing device inputs to the protective relays shall be verified, just that they be verified according to the established intervals. Please see Section 15.2 of the Supplementary Reference Document for a discussion on this topic.				
Christopher L de Graffenried	Consolidated Edison Co. of New York	1	Negative	PRC-005 Initial Ballot Comments: 1. The Tables - The wording "Component Type" is not necessary in each title. Just the equipment category should be listed--what is now shown as "Component Type - Protective Relay", should be Protective Relay. However, Protective Relay is too general a category. Electromechanical relays, solid state relays, and microprocessor based relays should have their own separate tables. So instead of reading Protective Relay in the title, it should read Electromechanical Relays, etc. This will lengthen the standard, but will simplify reading and referring to the tables, and eliminate confusion when looking for information. The "Note" included in the heading is also not necessary. "Attributes" is also not necessary in the column heading, "Component" suffices. 2. Other Comments - In general, the standard is overly prescriptive and complex. It should not be necessary for a standard at this level to be as detailed and complex as this standard is. Entities working with manufacturers, and knowledge gained from experience can develop adequate maintenance and testing programs. 3. Why are "Relays that respond to non-electrical inputs or impulses (such

Voter	Entity	Segment	Vote	Comment
				as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation)…" not included? The output contacts from these devices are oftentimes connected in tripping or control circuits to isolate problem equipment. 4. Due to the critical nature of the trip coil, it must be maintained more frequently if it is not monitored. Trip coils are also considered in the standard as being part of the control circuitry. Table 1-5 has a row labeled "Unmonitored Control circuitry associated with protective functions", which would include trip coils, has a "Maximum Maintenance Interval" of "12 Calendar Years". Any control circuit could fail at any time, but an unmonitored control circuit could fail, and remain undetected for years with the times specified in the Table (it might only be 6 years if I understand that as being the trip test interval specified in the table). Regardless, if a breaker is unable to trip because of control circuit failure, then the system must be operated in real time assuming that that breaker will not trip for a fault or an event, and backup facilities would be called upon to operate. Thus, for a line fault with a "stuck" breaker (a breaker unable to trip), instead of one line tripping, you might have many more lines deloaded or tripped because of a bus having to be cleared because of a breaker failure initiation. The bulk electric system would have to be operated to handle this contingency. 5. In reference to the FAQ document, Section 5 on Station dc Supply, Question K, clarification is needed with respect to dc supplies for communication within the substation. For example, if the communication systems were run off a separate battery in separate area in a substation, would the standard apply to these batteries or not? 6. To define terms only as they are used in PRC-005-2 is inviting confusion. Although they may be unique to PRC-005-2, some or all of them may be used in future standards, some already may be used in existing standards, and may or may not be deliberately defined. Consistency must be maintained, not only for administrative purposes, but for effective technical communications as well. 7. What is the definition of "Maintenance" as used in the table column "Maximum Maintenance Interval"? Maintenance can range from cleaning a relay cover to a full calibration of a relay. 8. A control circuit is not a component, it is made up of components. 9. Sub-requirement 1.5 needs to be clarified. It is not clear what "Identify calibration tolerances or other equivalent parameters…" means, and may be subject to different interpretations by entities and compliance

Voter	Entity	Segment	Vote	Comment
				enforcement personnel. 10. In the Implementation plan for Requirement R1, recommend changing "six" to fifteen. This change would restore the 3-month time difference that existed in the previous draft, between the durations of the implementation periods for jurisdictions that do and do not require regulatory approval. It will ensure equity for those entities located in jurisdictions that do not require regulatory approval, as is the case in Ontario. 11. The 'box' for "Monitored Station dc supply…" in Table 1-4 is not clear. It seems to continue to the next page to a new box. There are multiple activities without clear delineation. 12. Regarding station service transformers, Item 4.2.5.5 under Applicability should be deleted. The purpose of this standard is to protect the BES by clearing generator, generator bus faults (or other electrical anomalies associated with the generator) from the BES. Having this standard apply to generator station service transformers, that have no direct connection to the BES, does meet this criteria. The FAQs (III.2.A) discuss how the loss of a station service transformer could cause the loss of a generating unit, but this is not the purpose of PRC-005. Using this logic than any system or device in the power plant that could cause a loss of generation should also be included. This is beyond the scope of the NERC standards.

Response: Thank you for your comments.

1. The SDT believes that the table headings are appropriate as reflected in the draft standard.

2. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. Further, FERC Order 693 directs NERC to establish maximum allowable intervals, which implies that minimum activities also need to be prescribed. If an entities' experience is that components require less-frequent maintenance, a performance-based program in accordance with Requirement R3 and Attachment A is an option.

3. The SDT concentrated their efforts on protective relays which use the entire group of component types within the Protection System definition. Also, there is currently no technical basis for the maintenance of the devices which respond to non-electrical quantities on which to base mandatory standards related either to activities or intervals. Absent such a technical basis, we are currently unable to establish mandatory requirements, but may do so in the future if such a technical basis becomes available.

4. According to Table 1-5, trip coils of interrupting devices must be verified to operate every 6 years, rather than the 12-year interval. You can maintain these devices more frequently if you desire.

5. With respect to dc supply associated only with communication systems, we prescribe, within Table 1-2, that the communications system must be verified as functional every 3 months, unless the functionality is verified by monitoring. The specific station dc supply requirements (Table 1-4) do not apply to the dc supply associated only with communications systems. The SDT decided to

Voter	Entity	Segment	Vote	Comment
eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. 6. The SDT has proposed these terms for use only within PRC-005-2 because we are concerned that other uses of these terms, either now or in the future, may not be consistent with the terms used here. They are defined only for clarify within this standard. The SDT will confirm with NERC staff that this approach is acceptable. 7. As used in the "Maximum Maintenance Interval" column title of the table, maintenance refers to whatever activities are specified in the Activities column. The term is capitalized in the column title in conformance with normal editorial practice as a title, rather than as a definition. 8. For purposes of this standard, the control circuit IS defined as one component type.. 9. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. 10. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan. 11. Table 1-4 has been further modified for clarity. 12. In response to many comments, including yours, the SDT has removed 4.2.5.5 from the Applicability of the standard.				
Robert W. Roddy	Dairyland Power Coop.	1	Negative	In Table 1-5 it is unclear which devices the Maximum Maintenance Intervals would be held to, such as trip coils of circuit breakers and coils of electromechanical trip or auxiliary relays whose continuity and energization are monitored and alarmed.
Response: Thank you for your comments. Trip coils of circuit breakers have a 6-year interval for physical operation. Coils of lockout and auxiliary relays also have a 6-year interval for physical operation. Control circuitry whose continuity and energization or ability to operate are monitored and alarmed require no hands-on maintenance.				
John K Loftis	Dominion Virginia Power	1	Negative	Dominion is opposed to this version because Requirement R1.5 is overly prescriptive, requiring an extraordinary level of documentation, with little anticipated improvement in reliability.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.				

Voter	Entity	Segment	Vote	Comment
George R. Bartlett	Entergy Corporation	1	Negative	The restructured tables are generally much clearer and the SDT is to be commended on their efforts. 1. However, we believe the Alarming Point Table needs additional clarification with regard to the Maximum Maintenance Interval. If an “alarm producing device” is considered to be a device such as an SCADA RTU, individual entity intervals for such a device would differ, and there isn’t necessarily a maximum interval established as there is for Protection System components. Also, if an entity’s alarm producing device maintenance is performed in sections and triggered by segment or component maintenance, there would essentially be multiple maximum intervals for the alarm producing device of that entity. On that basis, we suggest the interval verbiage be revised to “When alarm producing device or system is verified, or by sections as per the monitored component/protection system specified maximum interval as applicable”. Alternately, if the intention is to establish maximum intervals as simply being no longer than the individual component maintenance intervals as we suggest for inclusion above, then the verbiage should be revised to “When alarm producing component/protection system segment is verified”. In either case, are we to interpret monitored components with attributes which allow for no periodic maintenance specified as not requiring periodic alarm verification? 2. R1.5 calls for “identification of calibration tolerances or equivalent parameters…” whereas the associated VSL references “failure to establish calibration criteria….” and is listed as high. If R1.5 is to be included in this standard, then we suggest the severity level of a failure to simply “identify” or document such calibration tolerances would be analogous to the severity level(s) of a “failure to specify one" or the severity level should be consistent with the other elements of R1. Both cases appear to be more of a documentation issue as opposed to a failure to implement. Shouldn’t a failure to implement any necessary calibration tolerance be accounted for in R4? R1.5 calls for “identification of calibration tolerances or equivalent parameters for each Protection System Component Type….”. We believe the Supplementary Reference document should provide additional information and examples of calibration tolerances or equivalent parameters which would be expected for the various component types. Especially for any “equivalent” parameters which would be required for compliance for a component type besides protective relays. Adding Requirement 1.5 is a significant revision and raises questions as to how broadly an accuracy or equivalent parameter requirement and associated

Voter	Entity	Segment	Vote	Comment
				documentation would need to be addressed by entities and/or will be measured for compliance. Discussion on this new requirement does not seem to be addressed anywhere in the FAQ or Supplementary Reference documents. Additionally, to the best of our knowledge, the need for such a requirement was not brought up as a concern or comment on the prior draft version of this standard, and in the context of a requirement need, we don't believe it has been attributed to or actually poses any significant reliability risk. We do not believe this requirement is justified.
Response: **Thank you for your comments.** **1. The Maximum Maintenance Interval column entry in Table 2 has been revised to state, "When alarm producing Protection System component is verified" to clarify this.** **2. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Robert Martinko	FirstEnergy Energy Delivery	1	Negative	Please see FirstEnergy's comments submitted separately through the comment period posting.
Response: **Thank you for your comments.** **Please see our responses to your comments from the formal comment period.**				
Gordon Pietsch	Great River Energy	1	Negative	1. We believe that requiring an entity to identify calibration tolerances in their PSMP does not add a material benefit and does not contribute to increased reliability. In addition we believe that R1.5 should be rewritten to state that a Relay test report should show when a Relay fell out of tolerance. R4.2 should be rewritten to state that if a test report does show that a Relay was out of tolerance it should be required to show that resolution was initiated. 2. The Activities section of Table 1.3 should be revised to include that the signals do not have to come from energized voltage or current sensing devices. The current or voltage signals can come from a test set. Note: It may be difficult to energize CTs or VTs for large capacitor banks, reactors, or generating units.
Response: **Thank you for your comments.** **1. 2. Table 1-3 has been modified in consideration of your comments.				
Ajay Garg	Hydro One Networks, Inc.	1	Negative	Hydro One is casting a negative vote with the following comments: 1. The added requirement R1, Part 1.5 is vague and needs clarification. It is not clear what "Identify calibration tolerances or other equivalent parameters" means and as written will be subject to different interpretations by entities and compliance enforcement personnel. The addition of this new part of Requirement R1 that requires the Owners to "identify calibration tolerances or other equivalent parameters for each Protection System component type" is onerous and contributes little to the reliability of the BES. 2. Changes introduced to the Implementation Plan since the last posting are not consistent with respect to jurisdictions where no regulatory approval is required. The previously posted implementation for Requirement R1 required entities to be 100% compliant on the first day of the first calendar quarter three months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter six months following Board of Trustees adoption. The amended implementation plan changed the three-month time to twelve months in jurisdictions with regulatory approval required but left the same six-month time for the others. For consistency, the six months timeframe should be changed to fifteen months.
Response: **Thank you for your comments.** **1. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **2. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan.**				
Michael Moltane	International Transmission Company Holdings Corp	1	Negative	1. ITC votes "Negative" for the following reasons: Our negative ballot is based on our objection to the 6 year test interval for auxiliary relays. We believe our present maintenance period for auxiliary relays of 10 years is adequate. 2. We also object to the requirement to verify acceptable levels of current values are received by the protective relays. We believe our present current transformer testing practice adequately insures acceptable levels of current are received by the relays and have requested that this procedure be approved. Detailed comments are included with our

Voter	Entity	Segment	Vote	Comment
				responses to the 5 questions in the Comment Form associated with this proposed Standard revision.
Response: Thank you for your comments. 1. The SDT believes that the appropriate interval for devices such as aux or lockout relays remains at 6 years, as these devices contain "moving parts" which must be periodically exercised to remain reliable. 2. Please see our response in the Comment Form.				
Stan T. Rzad	Keys Energy Services	1	Negative	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuity, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10

Voter	Entity	Segment	Vote	Comment
				that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical 4. The VRF of R1 should be Low since the attached tables are essentially the PSMP.
Response: **Thank you for your comments.** **1. For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities related to the interrupting device trip coil.** **2. This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to 4.2.1 in consideration of your comment.** **3. The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.** **4. The SDT disagrees; the Tables establish the intervals and activities, and Requirement R1 addresses the establishment of an entity's individual PSMP.**				
Walt Gill	Lake Worth Utilities	1	Negative	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical 4. The VRF of R1 should be Low since the attached tables are essentially the PSMP. 5. Table 1-4 requires a comparison of measured battery internal ohmic value to battery baseline. Since battery manufacturers do not provide this value, it is unclear what the “baseline” values ought to be if an entity recently began performing this test (assuming it’s several years after the commissioning of the battery.) Would it be acceptable for an entity to establish baseline values based on statistical analysis of multiple test results specific to a given battery manufacturer and design? o Small entities with only one or two BES substations may not have enough components to take advantage of the expanded maintenance intervals afforded by a performance-based maintenance program. Aggregating

Voter	Entity	Segment	Vote	Comment
				these components across different entities doesn't seem too logical considering the variations at the sub-component level (wire gauge, installation conditions, etc.) 6. Trip circuits are interconnected to perform various functions. Testing a trip path may involve disabling other features (i.e. breaker failure or reclosing) not directly a part of the test being performed. Temporary modifications made for testing introduce a chance to unknowingly leave functions disabled, contacts shorted, jumpers lifted, etc. after testing has been completed. Trip coils and cable runs from panels to breaker can be made to meet the requirements for monitored components. The only portions of the circuitry where this may not be the case is in the inter and intra-panel wiring. Because such portions of the circuitry have no moving parts and are located inside a control house, the exposure is negligible and should not be covered by the requirements. Entities will be at increased compliance risk as they struggle to properly document the testing of all parallel tripping paths.

Response: **Thank you for your comments.**

1. **For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities related to the interrupting device trip coil.**
2. **This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1 in consideration to your comment.**
3. **The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.**
4. **The SDT disagrees; the Tables establish the intervals and activities, and Requirement R1 addresses the establishment of an entity's individual PSMP.**
5. **Typical baseline values for various types of lead-acid batteries can be obtained from the test equipment manufacturer, perhaps the battery vendor, and perhaps other sources for batteries that are already in service. For new batteries, the initial battery baseline ohmic values should be measured upon installation and used for trending.**
6. **The requirement relative to control circuitry does not explicitly require trip or functional testing of the entire path; it requires that entities verify all paths without specifying the method of doing so. Please see Section 15.5 of the Supplementary Reference Document for detailed discussion.**

Joe D Petaski	Manitoba Hydro	1	Negative	1. Implementation Plan (Timeline) for R1: In areas not requiring regulatory approval, the 6 month time frame proposed for R1 is not achievable and is not consistent with areas requiring regulatory approval. To be consistent, the effective date for R1 in jurisdictions where no regulatory approval is required should be the first day of the first calendar quarter 12 months after BOT approval. 2. VSLs: The high VSL for R1 "Failed to include all maintenance activities relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5" may be interpreted in different ways and should be further clarified. 3. Table 1-4: The requirements for batteries listed in Table 1-4 do not appear to be consistent with the comments in the FAQ Section (V 1A Example 1). Please see comments submitted during formal comment period for further detail. 4. Table 1-4: The requirement for a 3 month check on electrolyte level seems too frequent based on our experience. We would like to point out that although IEEE std 450 (which seems to be the basis for table 1-4) does recommend intervals it also states that users should evaluate these recommendations against their own operating experience.

Voter	Entity	Segment	Vote	Comment
Response: Thank you for your comments. 1. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan. 2. The SDT does not understand your concern; further details are needed. 3. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. 4. The SDT believes that the 3-month interval specified in the Standard is appropriate.				
Terry Harbour	MidAmerican Energy Co.	1	Negative	MidAmerican remains concerned that including requirements for testing of electromechanical trip or auxiliary devices (Table 1-5 Row 3) will in some cases require entire bus outages that will compromise the BES reliability due to the need for entities across the US to take multiple BES elements out of service during the testing. If this requirement is retained additional time should be included in the implementation plan to allow for system modifications, such as the installation of relay test switches, to potentially allow for this testing while minimizing testing outages.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.				
Saurabh Saksena	National Grid	1	Negative	National Grid believes that this new Requirement as written subjects the Transmission Owner, Generation Owner or Distribution Provider to vague interpretations of what the requirement means by compliance officials. The addition of the new part of Requirement R1 that requires the Owners to "identify calibration tolerances or other equivalent parameters for each Protection System component type" is too intrusive and divisive for what it brings to the reliability of the BES.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.				
Richard L. Koch	Nebraska Public Power District	1	Negative	1. The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the

Voter	Entity	Segment	Vote	Comment
				applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend deleting the words "and proper operation of malfunctioning components is restored." from the first sentence of the PSMP definition. I believe that failure to do so exceeds the scope of the SAR. 2. Applicability Part 4.2.2: The ERO does not establish underfrequency load-shedding requirements. Those requirements will be established by Reliability Standard PRC-006-1 when it is approved by FERC. I recommend changing Accountability Part 4.2.2. to "...installed to provide last resort system preservation measures." (Note this wording is consistent with the Purpose of PRC-006-0.) 3. Applicability Part 4.2.5.4 and 4.2.5.5: Station Service transformers provide energy to plant loads and not the BES. If these plant transformers are included, why not include the rest of the plant systems? I recommend deleting Applicability Part 4.2.5.4 and 4.2.5.5. 4. Requirement R4: The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend deleting the words "including identification of the resolution of all maintenance correctable issues" from the first sentence of the Requirement. I believe that failure to do so exceeds the scope of the SAR. 5. Requirement R4 Part 4.2: The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis

Voter	Entity	Segment	Vote	Comment
				of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend re-wording Requirement 4, Part 4.2 to state: "Verify that the components are within the acceptable parameters established in accordance with Requirement R1, Part 1.5 at the conclusion of the maintenance activities." I believe that failure to do so exceeds the scope of the SAR. 6. Measurement M4: The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend deleting the words: "and initiated resolution of identified maintenance correctable issues" from the last sentence of Measurement M4. I believe that failure to do so exceeds the scope of the SAR.

Response: **Thank you for your comments.**

1. **Corrective maintenance is included within PRC-005-2 only in that the initiation of resolution of maintenance-correctable issues (discovered during maintenance activities) is included. The SDT considers this inclusion to be appropriate and necessary as part of the maintenance program.**

Voter	Entity	Segment	Vote	Comment
2. Under frequency load shedding requirements, whether established by regional Entities (current practice) or by EC, are ERO requirements. **3. Clause 4.2.5.5 has been removed. Generator-connected station service transformers are essential to the continuing operation of the generation plant; therefore, protection on these system components is included within PRC-005-2 if the generation plant is a BES facility.** **4. Corrective maintenance is included within PRC-005-2 only in that the initiation of resolution of maintenance-correctable issues (discovered during maintenance activities) in included. The SDT considers the inclusion to be appropriate and necessary as part of the maintenance program.** **5. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **6. Corrective maintenance is included within PRC-005-2 only in that the initiation of resolution of maintenance-correctable issues (discovered during maintenance activities) in included. The SDT considers the inclusion to be appropriate and necessary as part of the maintenance program.**				
David H. Boguslawski	Northeast Utilities	1	Negative	1) Requirement 1.5 states “Identify calibration tolerances or other equivalent parameters for each Protection System component type that establish acceptable parameters for the conclusion of maintenance activities”. This requirement is too vague and requires that the owner develop his own acceptable calibration tolerances for “each” protection system component type. The Owners internally generated calibration tolerances would then be subjected to the personal interpretation of what this requirement means by compliance officials and auditors. The confusion and divisiveness that this requirement will create far outweigh its potential benefits. 2) Due to the critical nature of the trip coil, it should be maintained more frequently if it is not monitored. Hence, it would be prudent to increase the test frequency of unmonitored trip coil so that it is more frequent than monitored trip coil. 3) In reference to the FAQ document, Section 5 on Station dc Supply, Question K, clarification is needed with respect to dc supplies for communication within the substation. For example, if the communication systems were run off a separate battery in separate area in a substation, would the standard apply to these batteries or not? 4) In section D.1.3., the statement regarding data retention for R2 needs to be reworded. The words “performance based maintenance program” should be changed to “time based maintenance program”, since R2 refers to a time based maintenance program.

Voter	Entity	Segment	Vote	Comment
Response: Thank you for your comments. 1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. 2. According to Table 1-5, trip coils of interrupting devices must be verified to operate every 6 years, rather than the 12-year interval. You can maintain these devices more frequently if you desire. 3. With respect to dc supply associated only with communication systems, we prescribe, within Table 1-2, that the communications system must be verified as functional every 3 months, unless the functionality is verified by monitoring. The specific station dc supply requirements (Table 1-4) do not apply to the dc supply associated only with communications systems. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. Your comments have been considered within that activity. 4. The SDT concluded that R2 is redundant with R1, Part 1.4, and has deleted R2 (together with the associated Measure and VSL), and data retention that reflects the previous R2.				
Douglas G Peterchuck	Omaha Public Power District	1	Negative	The three newly added requirements not approved by the drafting team are confusing. 1. OPPD believes that Article 1.4 needs to be deleted from the standard. It is redundant and serves no purpose. 2. OPPD believes that Article 1.5 needs to be deleted from the standard. There is a major concern on what an “acceptable parameter” is and how it would be interpreted by the Regional Entities. 3. OPPD believes that Article 4.2 needs to be deleted from the standard. There is no need for this article if Article 1.5 is deleted.
Response: Thank you for your comments. 1. The SDT disagrees; Requirement R1, Part 1.4 supports Requirement R1, Part 1.2, and seems necessary to assure that entities have appropriately applied the longer intervals associated with monitored components. However, in consideration to your comment the SDT has revised R1.4 and has also removed R2 because of redundancy to Requirement R1, Part 1.4. 2. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. 3. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this..				
Chifong L. Thomas	Pacific Gas and Electric Company	1	Negative	1. PG&E submits a Negative vote on Draft 3 of PRC-005-2 due to the addition of Requirement R1, Part 1.5. We do not agree with the addition of Requirement R1, Part 1.5 to the standard, which requires the Owners to "identify calibration tolerances or other equivalent parameters for each Protection System component type". We feel this is too prescriptive and does not belong in the PSMP which should remain at a higher level of detail. This new requirement, as written, can subject the Transmission Owner, Generation Owner or Distribution Provider to vague interpretations

Voter	Entity	Segment	Vote	Comment
				of what the requirement means by compliance officials. Additionally, the new requirement could require documenting thousands of calibration tolerances or other equivalent parameters for companies such as PG&E that use many different types of relays. This level of detail does not belong in the PSMP and would make it nearly impossible to manage. Rather, the calibration tolerances used to test the protection system components should reside in the Transmission Owner, Generation Owner and Distribution Provider's test procedure documents, test macros, or relay instruction manuals. PG&E also has comments on the Implementation Plan document. 2. PG&E does not agree with the time frames listed for implementation of Requirements R1, R2, R3 and R4, as explained below: a. Implementation plan for Requirement R1: Time was extended from three months to twelve months following regulatory approval which we agree with. For those jurisdictions where no regulatory approval is required it would seem that the time frame should also be extended to at least twelve months following NERC Board approval. However, it is still listed as six months following NERC Board approval. b. Implementation plan for Requirements R2, R3 and R4: For Protection System Components with maximum allowable intervals less than 1 year, it does not make sense to require 100% compliance after twelve months following regulatory approval, when this is the same time frame for compliance with Requirement R1 for establishment of the new PSMP. The implementation time window for Requirements R2, R3 and R4 should follow the implementation of Requirement R1 which establishes the new PSMP. So the dates listed for 100% compliance with Requirements R2, R3 and R4 should all be pushed out by 12 months each. c. Following is a summary time line for suggested implementation requirements. o Months 1-12 Establish PSMP per R1 i. Month 12+ Begin performing maintenance under new PSMP ii. Month 24 100% compliance date for R2, R3, R4, for components with max allowable intervals less than 1 year. iii. 3 Calendar Years 100% compliance date for R2, R3, R4, for components with max allowable intervals 1 year or more, but 2 years or less.

Voter	Entity	Segment	Vote	Comment
				iv. 3 Calendar Years 30% compliance date for R2, R3, R4, for components with max allowable intervals of 6 years. v. 5 Calendar Years 60% compliance date for R2, R3, R4, for components with max allowable intervals of 6 years. vi. 7 Calendar Years 100% compliance date for R2, R3, R4, for components with max allowable intervals of 6 years. 3. Overall the updated standard is a huge improvement over Draft 2 in terms of structure of the tables and presentation, which simplifies the standard quite a bit. PG&E would have been in support of Draft 3 if the requirement R1.5 had not been added.
Response: **Thank you for your comments.** **1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **2. The Implementation Plan for R1 has been changed from six months to twelve months, and the Implementation Plan for Protection System Components with maximum allowable intervals less than 1 year has been changed from 12 months to 15 months in consideration of your comment. The Implementation Plan for R4 has been revised to add one year to all established dates.** **3. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition and that Requirement R1, Part 1.5 is not necessary. Therefore, it has been removed. The associated VSL has also been revised.**				
Brenda L Truhe	PPL Electric Utilities Corp.	1	Negative	PPL Electric Utilities (“PPL EU”) appreciate the hard work and efforts of the Standards Drafting Team in reaching this point in the standards development process. The basis for the negative vote is the addition of Requirement R1.5 (calibration tolerances) and R4.2 to the standard. This requirement will provide the opportunity for auditors to decide if the testing criteria for whether a relay passes a test or not is acceptable. PPL EU recommends that Requirement R1.5 be deleted from the standard.
Response: **Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Kenneth D. Brown	Public Service Electric and Gas Co.	1	Negative	The PSEG Companies do not agree with the Facilities as currently described in section 4.2.5.5. Please refer to detailed comments provided in the formal Comment Form.
Response: **Thank you for your comments. Please see our responses to your comments from the formal comment period.**				

Voter	Entity	Segment	Vote	Comment
Pawel Krupa	Seattle City Light	1	Negative	Comment: The proposed Standard PRC-005-2 is an improvement over the previous draft in that it provides more consistency in maintenance and testing duration internals. Notwithstanding, two issues are of concern to Seattle City Light such that it is compelled to vote no: 1) the establishment of bookends for standard verification and 2) the implementation timelines for entities with systems where electro-mechanical relays still compose a significant number of components in their protection systems. 1. Bookends: Proposed Standard PRC-005-2 specifies long inspection and maintenance intervals, up to 12 years, which correspondingly exacerbates the so-called “bookend” issue. To demonstrate that interval-based requirements have been met, two dates are needed - bookends. Evidencing an initial date can be problematic for cases where the initial date would occur prior to the effective date of a standard. NERC has provided no guidance on this issue, and the Regions approach it differently. Some, such as Texas Regional Entity, require initial dates beginning on or after the effective date of a Standard. Compliance with intervals is assessed only once two dates are available that occur on or after a standard took effect. Other regions, such as Western Electricity Coordinating Council (WECC), require that entities evidence an initial date prior to the effective date of a standard. For WECC, compliance with intervals is assessed as soon as a standard takes effect. Such variation makes application of standards involving bookends uncertain, arbitrary, capricious, and in the case of WECC, possibly illegal. Proposed Standard PRC-005-2 will be another such standard. Indeed this Standard will involve by far the largest number of bookends of any NERC standard - many thousands for a typical entity. Furthermore, the long inspection and maintenance intervals introduced in the draft will require entities in WECC, for instance, to evidence initial bookend dates prior to the date original PRC-005-1 took effect. For the 12-year intervals for CTs and VTs in proposed Standard PRC-005-2, many initial dates will occur prior to the 2005 Federal Power Act that authorized Mandatory Reliability Standards and even reach back before the 2003 blackout that catalyzed the effort to pass the Federal Power Act. As a result, many entities in WECC maybe at risk of being found in violation of proposed Standard PRC-005-2 immediately upon its implementation. Seattle City Light requests that NERC address the bookends issue, either within proposed Standard PRC-005-2 or in a

Voter	Entity	Segment	Vote	Comment
				separate, concurrent document. 2. Legacy Systems: Many entities still have legacy protection systems that rely upon electro-mechanical relays. Effective testing approaches differ between electro-mechanical and digital relay systems. Thus, although the proposed standard rightly looks to the future of digital relays by specifying testing and maintenance focused on protection systems as a whole, the proposed implementation timelines create a level of hardship for those utilities with legacy systems. In example, auxiliary relay and trip coil testing may be essential to prove the correct operation of complex, multi-function digital protection systems. However, for legacy systems with single-function electro-mechanical components, the considerable documentation and operational testing needed to implement and track such testing is not necessarily proportional to the relative risk posed by the equipment to the bulk electric system. Performance testing of electro-mechanical systems, particularly regarding control circuits, will require extensive disconnection and reconnection of portions of the circuits. Such activities will likely cause far more problems on restoration-to-service than they will locate and correct. As such, to assist entities in their implementation efforts, we believe provision of alternatives are necessary, such as additional implementation time through phasing and/or through technical feasability exceptions.
Response: **Thank you for your comments.** 1. **This issue has been addressed by NERC in Compliance Application Notice CAN-008 "PRC-005 R2 Pre-June 18 Evidence".** 2. **Please see Sections 8 and 15.3 of the Supplementary Reference Document for a discussion on this topic. FERC Order 693 directs that NERC establish requirements for the maintenance of the Protection System and control circuitry is a portion thereof. Therefore, requirements for the maintenance of the control circuitry are necessary and the SDT has developed those requirements in a fashion that affords entities with the opportunity to best meet those requirements.**				
Horace Stephen Williamson	Southern Company Services, Inc.	1	Negative	Reference the new Requirements R.1.5 and R.4.2 which are new to this posting: R.1.5 requires the Owners to "identify calibration tolerances or other equivalent parameters for each Protection System component type" is too intrusive and divisive for what it brings to the reliability of the BES. The entire SDT needs to thoroughly discuss these new requirements and modify or delete them. Note: We have also made various requests for clarification to the FAQ and Supplemental Reference document in our Response to Comments which we are not including here.

Larry Akens	Tennessee Valley Authority	1	Negative	NERC is making significant changes to this sizeable standard and only allowing minimum comment period. While this is a good standard that has clearly taken many hours to develop, we are primarily voting “NO” because of the hurried fashion it is being commented, voted, and reviewed.
Response: **Thank you for your comments. Because of the urgent priority placed on this Standard by NERC, this Standard was posted for a 30-day formal comment period with a concurrent 10-day ballot period at the conclusion of that comment period, even though the Standard Development Process allows for a maximum 45-day formal comment period.**				
Brandy A Dunn	Western Area Power Administration	1	Negative	1) Western disagrees with the requirement R1, Part 1.5 that requires identifying "calibration tolerances or equivalent parameters for each Protection System component~" This requirement will add a burdensome, manual documentation of thousands of tolerances and parameters that are now part of multiple automated software programs and routines. These programs were purchased and developed over numerous years of testing experience by Western and testing equipment manufacturers. The fact that these tolerance and parameters are automated to Pass/Fail program notifications, gives our Maintenance Divisions repeatable testing programs that are not dependent on personnel interpretations. Extracting all these tolerances and parameters from these programs provides no benefit for our PSMP. 2) Western disagrees with the wording of the R4.2 requirement referencing the Part 1.5 of R1. The requirements of R4 are that you are to perform the appropriate maintenance activity and the associated testing. The fact that the testing was done and the equipment passed the testing meets the compliance for R4. If the equipment fails the testing, it then becomes a maintenance correctable issue, that requires adjustment or replacing, with further testing until the equipment passes the required testing. Documenting thousands of tolerances and parameters, for possibly thousands of components, serves no useful purpose for our PSMP or compliance documentation.
Response: **Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Gregory L Pieper	Xcel Energy, Inc.	1	Negative	“We feel that several improvements were made since the last draft. However, we feel that some gaps exist that should be addressed before moving this project forward. We have detailed our issues in our formal comments.”
Response: **Thank you for your comments. Please see our responses to your comments from the formal comment period.**				

Voter	Entity	Segment	Vote	Comment
Kim Warren	Independent Electricity System Operator	2	Negative	1. Requirement R1, Part 1.5 is vague and needs clarification. It is not clear what "Identify calibration tolerances or other equivalent parameters" means and this may be subject to different interpretations by entities and compliance enforcement personnel. 2. Additionally, in the Implementation plan for Requirement R1, we recommend changing "six" to "fifteen" to restore the 3-month time difference between the durations of the implementation periods for jurisdictions that do and don't require regulatory approval, which existed in the previous draft. This change will ensure equity for those entities located in jurisdictions that do not require regulatory approval as is the case here in Ontario. More importantly it supports the IESO's strong belief in the principle that reliability standards should be implemented in an orderly and coordinated fashion across regions to ensure system reliability is not compromised.
Response: **Thank you for your comments.** **1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **2. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan**				
Richard J. Mandes	Alabama Power Company	3	Negative	Reference the new Requirements R.1.5 and R.4.2 which are new to this posting: R.1.5 requires the Owners to "identify calibration tolerances or other equivalent parameters for each Protection System component type" is too intrusive and divisive for what it brings to the reliability of the BES. Raj Rana	American Electric Power	3	Negative	Restructured Tables: 1. Table 1.5 (Control Circuitry), row 4, indicates a maximum interval of 12 years for unmonitored control circuitry, yet other portions of control circuitry have a maximum interval of 6 years. AEP does not understand the rationale for the difference in intervals, when in most cases, one verifies the other. Also, unmonitored control circuitry is capitalized in row 4 such that it infers a defined term. 2. In the first row of table 1-4 on page 16, it is difficult to determine if it is a cell that wraps from the previous page or is a unique row. This is important because the Maximum Maintenance Intervals are different (i.e. 18 months vs 6 years). It is difficult to determine to which elements the 6 year Maximum Maintenance Interval applies. AEP suggests repeating the heading "Monitored Station dc supply (excluding UFLS and UVLS) with: Monitor and alarm for variations from defined levels (See Table 2):" for the bullet points on this page. VSLs, VRFs and Time Horizons: 3. The VSL table should be revised to remove the reference to the Standard Requirement 1.5 in the R1 "High" VSL. 4. All four levels of the VSL for R2 make reference to a "condition-based PSMP." However, nowhere in the standard is the term "condition-based" used in reference to defining ones PSMP. The VSL for R2 should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term "condition-based" within the Standard Requirements and Table 1. 5. In multiple instances, Table 1 uses the phrase "No periodic maintenance specified" for the Maximum Maintenance Interval. Is this intended to imply that a component with the designated attributes is not required to have any periodic maintenance? If so, the wording should more clearly state "No periodic maintenance required" or perhaps "Maintain per manufacturers recommendations." Failure to clearly state the maintenance requirement for these components leaves room for interpretation on whether a Registered Entity has a maintenance and testing program for devices where the Standard has not specified a periodic maintenance interval and the manufacturer states that no maintenance is required. FAQ and Supplementary Reference:

Voter	Entity	Segment	Vote	Comment
				6. With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications: a. Section 5 of the Supplementary Reference, refers to “condition-based” maintenance programs. However, nowhere in the standard is the term “condition-based” used in reference to defining ones PSMP. The Supplementary Reference should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term “condition-based” within the Standard Requirements and Table 1. b. Section 15.7, page 26, appears to have a typographical error “...can all be used as the primary action is the maintenance activity…” c. Figure 2 is difficult to read. The figure is grainy and the colors representing the groups are similar enough that it is hard to distinguish between groups. “Frequently-Asked Questions”: 7. With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications: a. The section “Terms Used in PRC-005-2” is blank and should be removed as it adds no value. b. Section I.1 and Section IV.3.G reference “condition-based” maintenance programs. However, nowhere in the standard is the term “condition-based” used in reference to defining ones PSMP. The FAQ should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term “condition-based” within the Standard Requirements and Table 1. c. The second sentence to the response in Section I.1 appears to have a typographical error “... an entity needs to and perform ONLY time-based…”. General:

Voter	Entity	Segment	Vote	Comment
				8. Standards Requirement 1.5 and the reference to R1.5 in Requirement 4.2 should be removed. Specifying calibration tolerances for every protection system component type, while a seemingly good idea, represents a substantial change in the direction of the standard. It would be very onerous for companies to maintain a list of calibration tolerances for every protection system component type and show evidence of such at an audit. AEP believes entities need the flexibility to determine what acceptance criteria is warranted and need discretion to apply real-time engineering/technician judgment where appropriate. 9. Three different types of maintenance programs (time-based, performance-based and condition-based) are referenced in the standard or VSLs, yet the time-based and condition-based programs are neither defined nor described. Certain terms defined within the definition section (such as Countable Event or Segment) only make sense knowing what those three programs entail. These programs should be described within the standard itself and not assume a knowledge of material in the Supplementary Reference or FAQ. 10. “Protective relay” should be a defined term that lists relay function for applicability. There are numerous ‘relays’ used in protection and control schemes that could be lumped in and be erroneously included as part of a Protection System. For example, reclosing or synchronizing relays respond to voltage and hence could be viewed by an auditor as protective relays, but they in fact perform traditional control functions versus traditional protective functions. 11. The Data Retention requirement of keeping maintenance records for the two most recent maintenance performances is a significant hurdle for any owners to abide by during the initial implementation period. The implementation plan needs to account for this such that Registered Entities do not have to provide retroactive testing information that was not explicitly required in the past.

Response: **Thank you for your comments.**

1. **The 6-year activities are all related to components with “moving parts”, and the 12-year activities are related to the other portions of the control circuitry. The capitalized term has been corrected and additional changes have been made.**

2. **Table 1-4 has been modified in consideration of your comments.**

3. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. The associated VSL has also been revised.**

Voter	Entity	Segment	Vote	Comment

4. The SDT concluded that Requirement R2 is redundant to Requirement R1, Part 1.4 and has deleted Requirement R2 (together with the Measures and & VSL).

5. If the indicated monitoring attributes are present, no "hands-on" periodic maintenance is required, as the monitoring of the component is providing a continuing indication of its functionality.

6. The discussion within the Supplementary Reference and FAQ are informative, not normative, and thus do not belong as part of the standard.

    D. The Supplementary Reference Document discusses condition-based maintenance in a conceptual manner, as a generally-recognized term. The SDT did make some changes within the Supplementary Reference document to clarify the manner in which condition-based maintenance is discussed. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.

    E. This clause has been corrected.

7. The discussion within the Supplementary Reference and FAQ are informative, not normative, and thus do not belong as part of the standard.

    b) The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.
    c) The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.
    d) The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.

8. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.

9. The term, "condition-based" has been removed from the draft standard. The other terms are used, but are clear in the context in which they are used.

10. "Protective relay" is defined by IEEE, and the SDT sees no need to either change the definition or to repeat the definition with PRC-005. Further, the applicability of generically-described protective relays is defined by the Applicability clause of PRC-005-2.

11. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.

Rebecca Berdahl	Bonneville Power Administration	3	Negative	Please refer to BPA's submitted comments on 12/16/10.
Response: **Thank you for your comments. Please see our responses to your comments from the formal comment period.**				
Steve Alexanderson	Central Lincoln PUD	3	Affirmative	WECC does not use the definition of the BES that NERC supplied to FERC via http://www.nerc.com/docs/docs/ferc/RM06-16-6-14-07CompFilingPar77ofOrder693FINAL.pdf, so the answer to FAQ III.1.3 (page 19-20) is not accurate.
Response: **Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.**				
Gregg R Griffin	City of Green Cove Springs	3	Negative	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuitry, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry.

Voter	Entity	Segment	Vote	Comment
				2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical 4. the VRF of R1 should be Low since the attached tables are essentially the PSMP.
Response: **Thank you for your comments.** **1. For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities related to the interrupting device trip coil.** **2. This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1 in consideration of your comments.** **3. The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.** **4. The SDT disagrees; the Tables establish the intervals and activities, and Requirement R1 addresses the establishment of an entity's individual PSMP.**				
Bruce Krawczyk	ComEd	3	Negative	The addition of the requirement R1.5 and associated wording has resulted in Exelon to vote No on the standard. While Exelon does specify Protection System tolerances and parameters in many maintenance documents; attempting to establish documented requirements for each component type is not practical. Additionally, this can leave much to the discretion of an auditor as to how in-depth tolerances need to be. There are many equipment and applications variations, many of which can utilize generic values while others require very specific value

Voter	Entity	Segment	Vote	Comment
				ranges. There are many instances where a very specific component tolerance is required for one application, but the same component doesn't require a tolerance in a different application. This could lead to entities having to justify why one application with a common component requires a narrow range versus the same component in another application can use a generic value or no tolerance. The last part of the requirement is also not clear. If a parameter is established, the R1.5 requirement is inferring component must meet an acceptable parameter to conclude the maintenance activity. There are many instances when a component is found out of a tolerance, but the level does not require immediate action and can even be scheduled for remediation at the next maintenance cycle. The wording in R1.5 appears to conflict with the R4.2 which indicates maintenance activities can be conclude as long as corrective maintenance is initiated as a result of identifying the condition.
Response: **Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Peter T Yost	Consolidated Edison Co. of New York	3	Negative	The Tables - 1. The wording "Component Type" is not necessary in each title. Just the equipment category should be listed--what is now shown as "Component Type - Protective Relay", should be Protective Relay. However, Protective Relay is too general a category. Electromechanical relays, solid state relays, and microprocessor based relays should have their own separate tables. So instead of reading Protective Relay in the title, it should read Electromechanical Relays, etc. This will lengthen the standard, but will simplify reading and referring to the tables, and eliminate confusion when looking for information. 2. The "Note" included in the heading is also not necessary. "Attributes" is also not necessary in the column heading, "Component" suffices. Other Comments – 3. In general, the standard is overly prescriptive and complex. It should not be necessary for a standard at this level to be as detailed and complex as this standard is. Entities working with manufacturers, and knowledge gained from experience can develop adequate maintenance and testing programs. 4. Why are "Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation)..." not included? The output contacts from these devices

Voter	Entity	Segment	Vote	Comment
				are oftentimes connected in tripping or control circuits to isolate problem equipment. 5. Due to the critical nature of the trip coil, it must be maintained more frequently if it is not monitored. Trip coils are also considered in the standard as being part of the control circuitry. Table 1-5 has a row labeled "Unmonitored Control circuitry associated with protective functions", which would include trip coils, has a "Maximum Maintenance Interval" of "12 Calendar Years". Any control circuit could fail at any time, but an unmonitored control circuit could fail, and remain undetected for years with the times specified in the Table (it might only be 6 years if I understand that as being the trip test interval specified in the table). Regardless, if a breaker is unable to trip because of control circuit failure, then the system must be operated in real time assuming that that breaker will not trip for a fault or an event, and backup facilities would be called upon to operate. Thus, for a line fault with a "stuck" breaker (a breaker unable to trip), instead of one line tripping, you might have many more lines deloaded or tripped because of a bus having to be cleared because of a breaker failure initiation. The bulk electric system would have to be operated to handle this contingency. 6. In reference to the FAQ document, Section 5 on Station dc Supply, Question K, clarification is needed with respect to dc supplies for communication within the substation. For example, if the communication systems were run off a separate battery in separate area in a substation, would the standard apply to these batteries or not? 7. To define terms only as they are used in PRC-005-2 is inviting confusion. Although they may be unique to PRC-005-2, some or all of them may be used in future standards, some already may be used in existing standards, and may or may not be deliberately defined. Consistency must be maintained, not only for administrative purposes, but for effective technical communications as well. 8. What is the definition of "Maintenance" as used in the table column "Maximum Maintenance Interval"? Maintenance can range from cleaning a relay cover to a full calibration of a relay. 9. A control circuit is not a component, it is made up of components. 10. Sub-requirement 1.5 needs to be clarified. It is not clear what "Identify calibration tolerances or other equivalent parameters…" means, and may be subject to different interpretations by entities and compliance enforcement personnel. 11. In the Implementation plan for Requirement R1, recommend changing

Voter	Entity	Segment	Vote	Comment
				"six" to fifteen. This change would restore the 3-month time difference that existed in the previous draft, between the durations of the implementation periods for jurisdictions that do and do not require regulatory approval. It will ensure equity for those entities located in jurisdictions that do not require regulatory approval, as is the case in Ontario. 12. The 'box' for "Monitored Station dc supply…" in Table 1-4 is not clear. It seems to continue to the next page to a new box. There are multiple activities without clear delineation. 13. Regarding station service transformers, Item 4.2.5.5 under Applicability should be deleted. The purpose of this standard is to protect the BES by clearing generator, generator bus faults (or other electrical anomalies associated with the generator) from the BES. Having this standard apply to generator station service transformers, that have no direct connection to the BES, does meet this criteria. The FAQs (III.2.A) discuss how the loss of a station service transformer could cause the loss of a generating unit, but this is not the purpose of PRC-005. Using this logic than any system or device in the power plant that could cause a loss of generation should also be included. This is beyond the scope of the NERC standards.

Response: **Thank you for your comments.**

1. The SDT believes that the table headings are appropriate as reflected in the draft standard.

2. The SDT believes that the table headings are appropriate as reflected in the draft standard.

3. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. Further, FERC Order 693 directs NERC to establish maximum allowable intervals, which implies that minimum activities also need to be prescribed. If an entities' experience is that components require less-frequent maintenance, a performance-based program in accordance with R3 and Attachment A is an option.

4. The SDT concentrated their efforts on protective relays which use the entire group of component types within the Protection System definition. Also, there is currently no technical basis for the maintenance of the devices which respond to non-electrical quantities on which to base mandatory standards related either to activities or intervals. Absent such a technical basis, we are currently unable to establish mandatory requirements, but may do so in the future if such a technical basis becomes available.

5. According to Table 1-5, trip coils of interrupting devices must be verified to operate every 6 years, rather than the 12-year interval. You can maintain these devices more frequently if you desire

6. With respect to dc supply associated only with communication systems, we prescribe, within Table 1-2, that the communications system must be verified as functional every 3 months, unless the functionality is verified by monitoring. The

Voter	Entity	Segment	Vote	Comment
specific station dc supply requirements (Table 1-4) do not apply to the dc supply associated only with communications systems. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. 7. The SDT has proposed these terms for use only within PRC-005-2 because we are concerned that other uses of these terms, either now or in the future, may not be consistent with the terms used here. They are defined only for clarify within this standard. 8. As used in the "Maximum Maintenance Interval" column title of the table, maintenance refers to whatever activities are specified in the Activities column. The term is capitalized in the column title in conformance with normal editorial practice as a title, rather than as a definition. 9. For purposes of this standard, the control circuit IS defined as one component type. 10. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. 11. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for R1, making it consistent with the remainder of the Implementation Plan. 12. Table 1-4 has been further modified for clarity. 13. In response to many comments, including yours, the SDT has removed 4.2.5.5 from the Applicability of the standard.				
David A. Lapinski	Consumers Energy	3	Negative	We have the following comment on the revisions, specifically sub-requirement R1.12a, which states, "Set the maximum torque angle (MTA) to 90 degrees or the highest supported by the manufacturer.". We have no issue with this requirement on transmission lines that are 200 kV or greater. However, we do have a concern with applying requirement R1.12a on lower voltage lines now that the Transmission Relay Loadability Standard is being revised to included selected equipment 200 kV and below. The positive-sequence line angle on lower voltage lines, such as 69 kV or 46 kV, is significantly lower than 90 degrees. The positive-sequence line angle for 3/0 ACSR, for example, is only 55 degrees. Setting a 90 degree MTA on these lines would require a much larger reach setting to provide adequate line protection. In some cases, especially for lines with long spurs and poor line conductor, the increased reach setting may actually provide less loadability than a reach setting based on an MTA set at the positive-sequence line angle. A 90 degree MTA also dramatically reduces the resistive fault coverage for these lines. For these reasons, we would propose a modification to sub-

Voter	Entity	Segment	Vote	Comment
				requirement R1.12a as follows: Set the maximum torque angle (MTA) to 90 degrees or the highest supported by the manufacturer on 200 kV or greater transmission lines. Set the maximum torque angle (MTA) to the positive-sequence line angle on transmission lines less than 200 kV.
Response: **Thank you for your comments. This comment appears to apply to PRC-023-2 (Project 2010-17), which is a separate activity, and is not apparently relevant to PRC-005-2.**				
Michael F Gildea	Dominion Resources Services	3	Negative	Dominion is opposed to this version because Requirement R1.5 is overly prescriptive, requiring an extraordinary level of documentation, with little anticipated improvement in reliability.
Response: **Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Henry Ernst-Jr	Duke Energy Carolina	3	Negative	1. R1.4 and R1.5 need more information to provide clarity for compliance. It's unclear to us what the expectation is for compliance documentation for "monitoring attributes and related maintenance activities" in R1.4 and "calibration tolerances or other equivalent parameters" in R1.5. This is fairly straightforward for relays, but not for other component types. Either provide clarity or delete these requirements. 2. R4.2 - it is critical that more clarity be provided for R1.5 so that we can also understand what the compliance expectation is for R4.2 3. M4 - Need to clarify that these pieces of evidence are all "or", not "and" (i.e. any of the listed examples are sufficient for compliance). We reiterate the need for additional clarity on R1.5 and R4.2 such that compliance can be demonstrated for all component types. 4. Table 2 - We are fairly clear on the expectation for relays, but need more clarity on the expectation for other component types. Also, need to change the phrase "corrective action can be taken" to "corrective action can be initiated", consistent with the Supplementary Reference document. 5. VSL for R1 - Sub-requirement R1.3 appears to be missing. 6. Also, it's unclear to us what the expectation is for compliance documentation for "monitoring attributes and related maintenance activities" in R1.4 and "calibration tolerances or other equivalent parameters" in R1.5. This is fairly straightforward for relays, but not for other component types. 7. VSL for R4 - More clarity must be provided on the expectation for compliance documentation. This is a High VRF requirement, and there may only be a small number of maintenance-correctable items, hence a significant exposure to an extreme penalty. 8. There are typographical errors on the FAQ Requirements Flowchart (should

Voter	Entity	Segment	Vote	Comment
				be R4.1.1 and R4.1.2 instead of R4.4.1 and R4.4.2). 9. We have previously commented that the FAQ and Supplementary Reference documents should be made part of this standard. If that cannot be done, then more of the information in those documents needs to be included in the requirements in the standard to provide clarity. Compliance will only be measured against what is in the standard, and we need more clarity.

Response: Thank you for your comments.

1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.

2. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.

3. The SDT has provided examples of the sort of evidence that may serve to demonstrate compliance. The degree to which any single evidence type is sufficient is dependent on the completeness of the evidence itself. The Measure has been modified to clarify this point.

4. Table 2 has been modified to be clearer. "Taken" has been replaced with "Initiation" in consideration of your comment.

5. The High VSL for Requirement R1 has been revised in consideration of your comment.

6. The issues of "monitoring attributes" are discussed within Section 15.7 of the Supplementary Reference Document. As for Requirement R1, Part 1.5, the SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.

7. Examples of compliance documentation are included within Measure M4 and discussed within various clauses of the FAQ and within Section 15.7 of the Supplementary Reference Document.

8. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.

9. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT believes the entities should be able to implement the standard without the Supplementary Reference. However, the SDT is also convinced that many entities may find the supporting discussion rationale etc useful particularly to assist them in implementing the standard in an efficient manner.
