

GUIDANCE ON HOW TO ANALYZE DATA FROM A SCHOOL-BASED ORAL HEALTH SURVEY JULY 2013, UPDATED JUNE 2015 AND JULY 2017

Due to the technical nature of this topic, this information will be most helpful to data analysts, epidemiologists and statisticians.

Has your state, territory or local health agency conducted a school-based oral health survey?

If yes, then you probably have questions about how to appropriately weight and analyze the data to best represent the target population of your survey. The purpose of this document is to provide a basic framework for how to appropriately analyze data from a statewide school-based oral health survey that employed a complex sampling design. Because no one method is appropriate for all states/territories, we encourage you to read this document, and then contact ASTDD for additional guidance on analyzing data for your state/territory. Although this document is geared towards states and territories, the techniques are appropriate for other jurisdictions such as counties.

Because no one method is appropriate for all states/territories, we encourage you to read this document, and then contact ASTDD for additional guidance on analyzing data for your state/territory.

This topic is important because most oral health surveys employ a complex sampling design that may include stratification, unequal selection probabilities and clustering. To obtain valid point estimates, standard errors, and confidence intervals, analysis must account for the sampling design. Simply doing a weighted analysis using statistical procedures like SAS Proc Freq is not appropriate because the variance estimation in such programs use formulas appropriate for simple random sampling rather than complex sampling. These formulas do not account for stratification or clustering and may result in biased point estimates of population parameters (in an unweighted analysis) and/or underestimation of standard errors and confidence intervals for point estimates.

This document is limited to a discussion of data weighting and analysis. For additional information on how to conduct and use data from a school-based oral health survey, please refer to the Basic Screening Survey (BSS) tools developed by the Association of State and Territorial Dental Directors (ASTDD). These tools are available at the following website: www.astdd.org/basic-screening-survey-tool/.

Do you want to submit the data to the National Oral Health Surveillance System (NOHSS)?

NOHSS (www.cdc.gov/oralhealthdata/) is a collaborative effort between CDC's Division of Oral Health and ASTDD. NOHSS is designed to monitor the burden of oral disease, use of the oral health care delivery system, and the status of community water fluoridation on both a national and state level. NOHSS tracks oral health surveillance indicators based on data sources and surveillance capacity available to most states. The Council of State and Territorial Epidemiologists (CSTE) and the Chronic Disease Directors (CDD) were instrumental in developing the framework for chronic disease surveillance indicators, including the oral health indicators in NOHSS. If you follow the guidance provided in this document and ASTDD's sampling guidance document, your oral health data will meet the specifications for inclusion in NOHSS.

If you follow the guidance provided in this document and ASTDD's sampling guidance document, your oral health data will meet the specifications for inclusion in NOHSS.

Only oral health survey data that meet the following specifications are included in the NOHSS data system:

- The data are from a **statewide probability sample** of elementary schools.

- If a complex sampling scheme is used, the data must be weighted for the sampling scheme.
- ASTDD strongly suggests that, at minimum, 3rd grade children be screened. Grades K-2 as well as Head Start may also be screened and are included in the NOHSS website.

NOTE: In some cases a state may be unable to follow this guidance. For example, because of small school size and confidentiality issues, an IRB may require that school identifiers not be included in the dataset. If you encounter such issues, please contact ASTDD for additional guidance.

Once our oral health data has been collected, what steps do I need to take to prepare the data for analysis?

There are several steps you should take to prepare for the analysis phase of your survey. Carefully review each step and decide if it is appropriate for your situation.

Step 1: Enter the data into an electronic file that can be exported to an appropriate statistical package. Good options for data entry systems include Epi Info (<http://wwwn.cdc.gov/epiinfo/>) and Microsoft Access. To minimize or eliminate data entry errors it is important to have a “very smart” data entry system that can make a variety of checks on the data while it is being entered. Typically a useful data entry system checks each field for valid values, inconsistencies in data across fields, skip patterns, etc. A good data entry system, just like a good form, should be designed to be self-explanatory and easy to use. Examples of data entry systems using Epi Info and Access are available from ASTDD.

Steps to Take to Prepare for Analysis

- Enter the data
- Clean the data
- Determine number screened at each school
- Determine number in sampling interval
- Calculate weight factor

Step 2: Clean the data file. If you used a smart data entry system, there should be very few data entry errors. Make sure that each record includes the appropriate school code. A school code is necessary for calculating the weight factor that will be used in the analysis. For additional information on data cleaning and preemptive data cleaning techniques, refer to the following brief: <http://www2.sas.com/proceedings/sugi26/p015-26.pdf> . Once you have selected the data entry system and statistical software package to use, it may be helpful to read briefs or reference books specific to that system or package.

Step 3: Determine how many children were screened at each school. This can be accomplished by generating a frequency distribution for school codes. The number of children screened at each school will be used as the denominator in the weight factor calculation.

Step 4: Go back to the file you used to select the sample and determine how many children were enrolled in each sampling interval. Link the sampling interval information to the participating school codes. The number of children in the sampling interval will be partially dependent on the type of sampling strategy you used.

- If you used a probability proportional to size (PPS) sampling strategy, the number of children in the sampling interval will be the same for each sampling interval in a given strata. Refer to Example 1 and Table 1 (page 11).
- If you used a non-PPS sampling strategy, the number of children in the sampling interval will generally be different for each sampling interval. Refer to Example 2 and Table 2 (page 13).
- Refer to the school survey sampling guidance developed by ASTDD for additional information. The sampling guidance is available at the following site: www.astdd.org/basic-screening-survey-tool/.

Step 5: Calculate the weight factor using the following formula. Each child in a particular school and grade will have the same weight factor.

- $Weight = (\# \text{ of children in sampling interval}) / (\# \text{ of children screened in sampling interval})$
 - This formula reflects the reduction of the overall probability calculation of:

- $(\# \text{ enrolled in school} / \# \text{ in sampling interval}) * (\# \text{ children invited to participate} / \# \text{ enrolled in school}) * (\# \text{ screened} / \# \text{ children invited to participate}) = \# \text{ of children screened in sampling interval} / \# \text{ of children in sampling interval}$
- Note that number enrolled in school cancels out in the first and second terms and number of children invited to participate cancels out in the second and third terms
 - The analysis weight is the inverse of the reduced probability term: $(\# \text{ of children in sampling interval}) / (\# \text{ of children screened in sampling interval})$
 - **NOTE:** The number of children in the sampling interval is based on the sampling frame used for selecting the sample which generally will be from the school year prior to the data collection year. These numbers would be expected to be very close to current numbers.

What statistical software package and program code should I use?

Analysis of data from surveys that employ a complex sampling design, such as a school-based oral health survey, must account for the sampling design. Several statistical software packages are either (1) designed specifically to analyze complex sample survey data or (2) have special procedures or modules to correctly analyze complex sample survey data including SUDAAN, SAS, STATA, SPSS, Epi Info and R. All of these packages are appropriate for the analysis of school-based oral health survey data; your decision for which package to use will probably be based on availability, familiarity or cost. Both Epi Info and R are available at no cost to the user.

To help you with the analysis process, we have created sample program code for each of the packages listed and have compared results from each package based on a sample data set from a recent state oral health survey of kindergarten and 3rd grade children. Information about each statistical software package, except R, was excerpted from [Software for Analysis of YRBS Data](#) (CDC 2016).

Definition of variables used in the sample program code:

- Grade – K=kindergarten, 3=third grade
- Race – 1=white, 2=black
- Cluster – a unique number for each school, primary sampling unit (PSU)
- Strata – geographic region of the state, stratification variable used in selecting sample
- Weight – analysis weight factor ($\# \text{ children in sampling interval} / \# \text{ children screened in interval}$)
- Untreated – does the child have untreated decay (0=No, 1=Yes)
- Treated – does the child have treated decay (0=No, 1=Yes)
- Experience – does the child have treated and/or untreated decay (0=No, 1=Yes). You will need to create the variable “Experience” from “Treated” and “Untreated”
 - If Untreated is missing and Treated is missing then Experience should be coded missing
 - If Untreated=0 and Treated=0 then Experience=0
 - If Untreated=1 or Treated=1 then Experience=1
- Sealants – does the child have dental sealants (0=No, 1=Yes)

General items that deserve caution:

- Missing data: Each software package uses its own special coding for missing data, for example “.” in SAS and “N/A” in R. These special codes for missing data translate to numeric values in calculations, sometimes very small and sometimes very large. Take care in recoding or creating new variables to be sure that missing data are categorized as you intended.
- Subpopulation analyses, “By” statement dropping observations from data set: With complex sample data, to get estimates for a subpopulation, such as male or Hispanic children, the statistical software requires information about the sampling design, the strata, and primary sampling units (PSUs). Dropping observations from the data set for children who are not in the subpopulation can result in loss of information on some strata and PSUs, resulting in estimates that do not account for the correct number of strata and PSUs. Using a “By” statement to get estimates for males and females in SAS, for example, is

equivalent to doing the analysis once dropping all of the females, and then again dropping all of the males. **The “By” statement is NOT the recommended way to get estimates for subpopulations for many of the software packages.** Sudaan version 11 is an exception. Check the documentation for your preferred statistical software to be sure you are using the correct syntax for proper subpopulation analysis.

SAS sample code: SAS versions 8 and higher include special sample survey procedures that are appropriate for analyzing complex survey data. These sample survey procedures use SAS syntax that will be familiar to those who already use SAS. There are three sample design statements in SAS: CLUSTER, where the name of the primary sampling unit (PSU) is placed; STRATA, where the name of the stratification variable is placed; and WEIGHT, where the name of the analysis weight variable is placed. Variables may be numeric or character. The input data file does not need to be sorted by stratum and/or PSU variables before analysis.

Univariate analysis (data not presented):

```
PROC SURVEYFREQ ;  
STRATA strata ;  
CLUSTER cluster ;  
WEIGHT weight ;  
TABLES untreated experience sealants / cl ;  
RUN ;
```

Table 3:

```
PROC SURVEYFREQ ;

```

Table 4:

```
PROC SURVEYFREQ ;  
STRATA strata ;  
CLUSTER cluster ;  
WEIGHT weight ;  
TABLES grade*race*sealants / row cl ;  
RUN ;
```

Epi Info sample code: Epi Info includes a module for complex sample survey analysis. The analytic capabilities of Epi Info are limited and are oriented towards public health field work applications. Sample design information is entered into the appropriate box (Weight, PSU, Stratify by) in the dialog box that appears once an analysis (Complex Sample Frequencies, Complex Sample Tables, Complex Sample Means) has been selected. You can also use the syntax codes below. Variables may be numeric or character. The input data file does not need to be sorted by stratum and/or PSU variables before analysis. **IMPORTANT NOTE:** As of June 2015, Epi Info does not have the ability to appropriately generate subpopulation analyses. Using the “Select” statement will drop observations and may impact information about the sampling design, strata, and primary sampling units (PSUs). Dropping observations from the data set for children who are not in the subpopulation may result in loss of information on some strata and PSUs, resulting in estimates that do not account for the correct number of strata and PSUs.

Univariate analysis (data not presented):

```

R sample code: R is an open source, freely available software. Users develop R “packages” for specific purposes. Analysis of complex sample survey data requires the package “survey” developed by Thomas Lumley at University of Washington. Details of R can be found at the R-Project website <http://www.r-project.org/> and further details of the survey package can be found at <http://r-survey.r-forge.r-project.org/survey/index.html>. Variables may be numeric or character. The input data file does not need to be sorted by stratum and/or PSU variables before analysis.

```
#Describe the sample design to R
BSS <- svydesign(id=~Cluster, strat=~Strata, weight=~Weight, data=dat2)
```

Univariate analysis (data not presented):

```
uniana <- svymean(~Untreated+Experience+Sealants, BSS, na.rm = TRUE)
```

```
#Calculating Confidence Intervals
t1 <- ftable(uniana)
UniTab = data.frame(Mean = t1[,1], CintLow = t1[,1]-1.96*t1[,2], CintHigh = t1[,1]+1.96*t1[,2])
```

```

v1$Untreated = vun$Untreated
v1$cll.Untreated= v1$Untreated - 1.96*vun$se.Untreated
v1$clu.Untreated= v1$Untreated + 1.96*vun$se.Untreated
v1$Experience = vexp$Experience
v1$cll.Experience= v1$Experience - 1.96*vexp$se.Experience
v1$clu.Experience= v1$Experience + 1.96*vexp$se.Experience
v1$Sealants = vseal$Sealants
v1$cll.Sealants= v1$Sealants - 1.96*vseal$se.Sealants
v1$clu.Sealants= v1$Sealants + 1.96*vseal$se.Sealants

#Rounding Table Values
v1[,2:10] <- round(100*v1[,2:10],1)

```

Table 4:

```

v3Seal<-svyby(~Sealants, ~Grade+Race, svymean, design=BSS, keep.names=FALSE, na.rm = TRUE)

# Calculating Confidence Interval and Rounding
v3Seal$CintLow=v3Seal$Sealants - 1.96*v3Seal$se.Sealants
v3Seal$CintHigh=v3Seal$Sealants + 1.96*v3Seal$se.Sealants

v3Seal[,3:6] <- round(100*v3Seal[,3:6],1)

```

SUDAAN sample code: SUDAAN is specifically designed to analyze complex sample survey data. The user describes the sample survey design in three statements: (1) by specifying an option for the DESIGN keyword on the PROC statement, (2) by specifying the stratification and clustering (PSU) variables on the NEST design statement, and (3) by specifying the analysis weight variable on the WEIGHT design statement. **All variables must be numeric.** For this example, grade was changed for K and 3 to 0 and 3. Data should be sorted by the variables that appear on the NEST statement before analysis; otherwise procedure syntax must contain the NOTSORTED option.

Univariate analysis (data not presented):

```

proc descript data=bss design=wr conf_lim=95;
nest strata cluster;
weight weight;
var EXPERIENCE UNTREATED SEALANTS;
catlevel 1 1 1;
run;

```

Table 3:

```

proc descript data=bss design=wr conf_lim=95;
nest strata cluster;
weight weight;
class GRADE;
var EXPERIENCE UNTREATED SEALANTS;
catlevel 1 1 1;
tables GRADE;
run;

```

Table 4:

```
proc descript data=bss design=wr conf_lim=95;
nest strata cluster;
weight weight;
class RACE;
var SEALANTS;
catlevel 1;
tables RACE;
subpopn GRADE=3;
run;
```

STATA sample code: STATA version 7 or higher offers the capability to perform many statistical procedures on complex sample survey data. When performing menu-driven analyses, sample design information is entered into boxes on the MAIN (PSU and stratification variables) and WEIGHT (analysis weight variable) tabs of the dialogue box that appears after “declare survey design for data set” is chosen from the Survey Data Analysis menu. If syntax is written the information is included on the SVYSET statement. The survey design descriptors only need to be entered once at the beginning of the analysis session. Although variables in STATA data sets can be numeric or character, **all variables used in an analysis must be numeric**. The input data file does not need to be sorted by stratum and/or PSU variables before analysis.

Univariate analysis (data not presented):

```
Svyset Cluster [pweight = Weight], strata(Strata)
Svy linearized : proportion Sealants Untreated Experience
```

Table 3:

```
Svy linearized : proportion Sealants Untreated Experience, over(Grade)
```

Table 4:

```
Svy linearized : proportion Sealants Untreated Experience, over(Race Grade)
```

SPSS sample code: SPSS has an add-on module, SPSS Complex Samples, which includes sample selection and analysis of complex sample survey data. When performing menu-driven analysis, the sample design information is entered into a dialogue box when preparing for analysis and is saved as a sampling plan for the data set. Once the sampling plan has been created, it will be opened along with the data set at the beginning of an SPSS session. You can also use the following syntax code. Variables may be numeric or character. The input data file does not need to be sorted by stratum and/or PSU variables before analysis.

Comparison of results: Tables 3 and 4 compare the results from each of the aforementioned statistical software packages from a recent state oral health survey of kindergarten and 3rd grade children. Table 3 presents the prevalence of decay experience, untreated decay, and dental sealants by grade while the prevalence of dental sealants among 3rd grade children by race is presented in Table 4. **Each of the six statistical software packages described in this document can be used to appropriately analyze data from a school-based survey, although Epi Info may not appropriately account for the correct number of strata and PSUs in subpopulation analyses.**

Are there other things that I should consider or be aware of?

Yes, there are a variety of other issues that may impact your analysis or how you report your survey reports. Following is a short list that you should review. If you have additional questions or concerns please contact ASTDD.

- *Finite population correction:* If more than 10% of children from within any given strata are selected, you may want to consider using a finite population correction factor, which reduces variance yielding smaller standard errors and confidence intervals. For additional information on finite population correction refer to *Introduction to Survey Sampling*.
- *No data for a given sampling interval:* If a school refuses to participate, we encourage you to select a replacement school from the same sampling interval. Unfortunately, circumstances may result in an inability to screen the original or a replacement school in a given sampling interval. If this happens you should clearly report that you were not able to screen children in a sampling interval along with what that interval represented. For example, if you selected 70 schools but you only have data for 69, report that you are missing data from one sampling interval that represents children from region 3 attending schools where 30-40% of the children are eligible for the National School Lunch Program (NSLP).
- *Reporting response rates:* For each school in your survey, you should collect the number of children enrolled in the grade of interest on the day of the screening (or the number invited to participate if you did not invite all children in a given grade). Your response rate for the survey will be the number screened divided by the number enrolled or invited to participate.
- *Stratifying results by school NSLP percentage:* Many states use school NSLP percentage as a surrogate measure of socioeconomic status. We recommend using the current year NSLP status of the school if stratifying the results by NSLP; this information can be obtained from the school on the day of the screening.
- *Limitations of survey:* When preparing your survey report, it is important to clearly state any limitations of the survey including representativeness and response rate.
- *Confidence intervals:* Confidence intervals are important because they provide context for understanding the precision or exactness of a point estimate. The wider the confidence interval, the less exact the point value estimate becomes. Take, for example, a point estimate of 40% for the prevalence of dental caries experience. If the confidence interval of this point estimate is 35%-45%, then we can have greater certainty that the true prevalence is near 40% than if the confidence interval was 10-70%. For your data to be included in NOHSS, confidence intervals must be included (unless you screened all children in your target population).

Where can I get additional help?

ASTDD can help you with the survey analysis process. Please contact us if you have any questions.

Example #1
Weight factor calculation for a survey that used systematic PPS sampling with implicit stratification by region, urban/rural status and NSLP percent

This example shows the steps from sample selection to weight factor calculation when a probability proportional to size (PPS) sampling strategy is used. Based on available resources, the decision was made to include 70 schools in the “Utopia” oral health survey of 3rd grade children. The following sampling steps were employed:

- The sampling frame list was sorted by region then by urban/rural status within each region
- Schools were then sorted by percent of children participating in NSLP within urban/rural school categories.

Calculations used for selecting the systematic PPS sample:

- Sampling interval for sampling = (total 3rd grade enrollment) / (# of schools to be screened)
 - $53,320 / 70 = 761.7$
- Random start = random number between 0 and interval (761.7) = **148.0**
 - This is the first school selection number
 - There are a variety of methods for selecting a random number including, but not limited to, Excel and www.random.org
- Select the school with the 148th child. Add the sampling interval (761.7) to 148 to get the next school (909.7). Continue adding the sampling interval repeatedly until all 70 school selections are made.

148.0, 909.7, 1671.4, 2433.1, 3194.8, 3956.5, 4718.2, ...

- These numbers are matched to the cumulative enrollment numbers in the sampling list. The schools with enrollment intervals containing the sample selection numbers are selected into the sample. The sampling frame list and the selected schools are shown in Table 1.

Weight factor calculation (Table 1):

- Weight = (number of children in sampling interval) / (number of children screened)
- When PPS sampling is used the number of children in the sampling interval will always be the sampling interval used when selecting the sample, in this case, 761.7.

Table 1: Systematic PPS sampling with implicit stratification by region, urban/rural and NSLP participation

Example #2

Weight factor calculation for a survey that used systematic non-PPS sampling with implicit stratification by region, urban/rural status and NSLP percent

This example shows the steps from sample selection to weight factor calculation when a non-PPS sampling strategy is used. Based on available resources, the decision was made to include 70 schools in the “Utopia” oral health survey of 3rd grade children. The following sampling steps were employed:

- The sampling frame list was sorted by region then by urban/rural status within each region
- Schools were then sorted by percent of children participating in NSLP within urban/rural school categories.

Calculations used for selecting the systematic non-PPS sample:

- Sampling interval for sampling = (number of schools in sampling frame) / (# of schools to be screened)
 - $700 / 70 = 10.0$
- Random start = random number between 1 and interval (10) = 6.0
 - This is the first school selection number
 - There are a variety of methods for selecting a random number including, but not limited to, Excel and www.random.org
- Select the 6th school. Add the sampling interval (10.0) to 6 to get the next school (16.0). Continue adding the sampling interval repeatedly until all 70 school selections are made.

6.0, 16.0, 26.0, 36.0, 46.0, 56.0, 66.0, ...

- These numbers are matched to the sequential number of schools in the sampling list to identify the schools selected into the sample. The sampling frame list and the selected schools are shown in Table 2.

Weight factor calculation (Table 2):

- Weight = (number of children in sampling interval) / (number of children screened)
- When non-PPS sampling is used the number of children in the sampling interval will vary from one interval to another. The number of children in the sampling interval is the total of all 3rd grade children in the given interval.
- **NOTE:** In this example, dividing the number of schools by the number of schools to screen produced a whole number. Please contact ASTDD if you need more information on how to appropriately calculate weights if a fractional sampling interval was used.
