**The Final Consolidated Atlantic Highly Migratory Species Fishery Management Plan**

**Actions:** Consolidate the Fishery Management Plan for Atlantic Tunas, Swordfish, and Shark and the Atlantic Billfish Fishery Management Plan; establish workshops for fishermen and dealers; consider changes to time/area closures; address rebuilding and/or overfishing of northern albacore tuna, finetooth sharks, and Atlantic billfish; modify the management process of bluefin tuna; change the fishing year; modify the authorized gears; implement minor changes and clarifications to the regulations; and begin the process to update essential fish habitat

**Type of Statement:** Final Environmental Impact Statement; Final Regulatory Impact Review; Final Regulatory Flexibility Analysis; Final Social Impact Statement; and Final Framework Actions

**Lead Agency:** National Marine Fisheries Service

**For Further Information:** Karyl Brewster-Geisz

**Abstract:** In 2003, the National Marine Fisheries Service (NMFS) began the process to amend the Fishery Management Plan for Atlantic Tunas, Swordfish, and Sharks and the Atlantic Billfish Fishery Management Plan. After considering comments on a scoping paper and on a predraft document, NMFS decided to consolidate these fishery management plans, modify the fishery management plan management measures as necessary, implement framework actions, and begin the process for updating essential fish habitat. The draft of this document was released on August 19, 2005. The comment period was open until March 1, 2006. During this time, 24 public hearings were held throughout the coastal states from Maine through Texas and the Caribbean. The final document describes a range of alternatives that could impact fishermen and dealers for all highly migratory species fisheries. The preferred alternatives include those to: establish mandatory workshops for fishermen and dealers; implement two small closures, consistent with regulations implemented by the Gulf of Mexico Fishery Management Council; establish criteria for modifying and/or establishing time/area closures; address rebuilding and/or overfishing of northern albacore tuna, finetooth sharks, and Atlantic billfish; modify the management process of bluefin tuna; change the fishing year for tunas, swordfish, and billfish back to a calendar year; authorize additional fishing gears; and clarify the regulations.

## EXECUTIVE SUMMARY

Atlantic Highly Migratory Species (HMS) are managed under the dual authority of the Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act) and the Atlantic Tunas Convention Act (ATCA). Under the Magnuson-Stevens Act, the National Marine Fisheries Service (NMFS) must manage fisheries to maintain optimum yield (OY) by rebuilding overfished fisheries and preventing overfishing. Under ATCA, NMFS is authorized to promulgate regulations, as may be necessary and appropriate, to implement the recommendations from the International Commission for the Conservation of Atlantic Tunas (ICCAT). Before this action, tunas, swordfish, and sharks were managed under the 1999 Fishery Management Plan (FMP) for Atlantic Tunas, Swordfish, and Sharks (and its 2003 amendment) and billfish were managed under the 1988 Atlantic Billfish FMP (and its 1999 amendment). This final HMS FMP combines the management of all Atlantic HMS into one FMP, and combines and simplifies the objectives of the previous FMPs.

NMFS announced its intent to prepare an Environmental Impact Statement to amend the two previous FMPs on July 9, 2003. In this notice, NMFS asked for comments on quota allocations of Atlantic bluefin tuna (BFT), swordfish, and sharks among and within domestic fishing categories; management alternatives to improve and streamline the current HMS limited access permit program; a review of HMS essential fish habitat (EFH) identifications; and exempted fishing and scientific research permitting issues. On April 30, 2004, NMFS announced the availability of an Issues and Options Paper and its intent to hold nine scoping meetings. This paper expanded the list of issues to include those issues listed above, additional issues for every species, HMS tournaments, bycatch reduction, recordkeeping and reporting, workshops, authorized fishing gears, and consolidation of the FMPs. NMFS presented the Issues and Options Paper to the New England, Mid-Atlantic, and Gulf of Mexico Fishery Management Councils and the Atlantic States Marine Fisheries Commission. A summary of the major comments received during scoping was released in December 2004 and is available on the HMS Management Division webpage at http://www.nmfs.noaa.gov/sfa/hms.

The Issues and Options paper included an exhaustive list of issues that NMFS could address regarding Atlantic HMS. During scoping, NMFS heard of more issues and options that merit additional consideration and examination. At the Predraft stage, in order to complete this action in a timely manner, NMFS decided to handle in this rulemaking only some of the issues identified in the Issues and Options paper and scoping process. NMFS prioritized the issues and chose to consider those that were required by law (*e.g.*, handling and release workshops are required under the 2004 Biological Opinion) and/or would improve the management of the fisheries (*e.g.*, amending the FMP for the BFT General Category should allow management to make changes in the fisheries on a more timely basis).

In February 2005, NMFS released the combined Predraft of the Consolidated HMS FMP and the 2005 Annual Stock Assessment and Fishery Evaluation (SAFE) Report. NMFS presented the Predraft document to all five Atlantic Fishery Management Councils, both the Gulf and Atlantic States Marine Fisheries Commissions, and to the HMS and Billfish Advisory Panels. Comments received on both the Issues and Options Paper and the Predraft were considered when drafting and analyzing the ecological, economic, and social impacts of the alternatives in both the draft and final HMS FMP. A summary of the comments received on the Predraft was released in June 2005 and is available on the HMS Management Division webpage. While some of the options changed between the Predraft and Draft stages, the overall list of issues to be addressed did not change.

On August 19, 2005, the draft HMS FMP and proposed rule were released. Originally, the comment period was set to end 60 days after publication (October 18, 2005). However, due to hurricanes Katrina and Rita, NMFS extended the comment period to March 1, 2006 (for a total comment period of 194 days), in order to ensure that those fishermen directly affected by the hurricanes would have an adequate amount of time to review the document and provide comment. Several thousand written comments were received, 24 public hearings were held, and all five Atlantic Fishery Management Councils and the Gulf and Atlantic States Marine Fisheries Commissions were given briefings. A summary of the public comments received and NMFS' response to those comments is included in an appendix of this document and will also be in the final rule implementing the regulations. In addition to the public comments, NMFS also had three independent scientists (*i.e.*, scientists not involved in the drafting of the document) review three specific sections of the draft HMS FMP. The three sections were the time/area analyses, the standardized bycatch reporting methodology, and the review of EFH. The peer review comments are also included in an appendix of this document.

The preferred alternatives in this document considered all of the comments received from the general public at all stages of the rulemaking and the peer review by the independent scientists. Table 1 provides the list of the changes from the draft document and the expected implementation date of each alternative. A summary of the issues addressed and the other alternatives considered in this rulemaking can be found below. More detail can be found in Chapters 2 and 4 of this document. The final HMS FMP also consolidates the objectives for the FMP (listed in Chapter 1) and removes the exemption to the billfish no sale provision (allowed for, but not implemented, in the 1988 Billfish FMP). NMFS believes that the suite of preferred alternatives in this document should, consistent with the Magnuson-Stevens Act and other domestic laws, allow overfished Atlantic HMS to rebuild, address overfishing of Atlantic HMS, balance the needs of the fishermen and communities with the needs of the resource, and maximize OY for the fishery and the resource.

**Table 1 The preferred alternatives at the draft and final stage of the Consolidated HMS FMP and the expected implementation date.**

| Preferred Alternative in Draft HMS FMP | Preferred Alternative in Final HMS FMP | Expected Implementation Date |
|---|---|---|
| *Bycatch Reduction: Workshops* | | |
| A2. Mandatory workshops and certification for all HMS pelagic and bottom longline vessel owners | Same | January 1, 2007: must complete certification prior to renewing HMS permit in 2007 |
| A3. Mandatory workshops and certification for vessel operators actively participating in HMS pelagic and bottom longline fisheries | Same | January 1, 2007: must complete certification prior to fishing on a vessel that has renewed its HMS permit in 2007 |
| A5. Mandatory workshops and certification for shark gillnet vessel owners and operators | Same | January 1, 2007: must complete certification prior to renewing HMS permit in 2007 |
| A6. Certification Renewal Timetable (Certification renewal every 3-years) | Same | 30 days after final rule is published |
| A9. Mandatory HMS identification workshops for all shark dealers | Same | December 31, 2007 |
| A16. Certification Renewal Timetable (Certification renewal every 3-years) | Same | 30 days after final rule is published |
| *Bycatch Reduction: Time/Area Closures* | | |
| B4. Implement complementary HMS management measures in Madison-Swanson and Steamboat Lumps Marine Reserves | Same | 30 days after final rule is published |
| B5. Establish criteria to consider when implementing new time/area closures or making modifications to existing time/area closures | Same | 30 days after final rule is published |
| *Rebuilding and Preventing Overfishing: Northern Albacore Tuna* | | |
| C3. Establish the foundation with ICCAT for developing an international rebuilding program | Same | 30 days after final rule is published |
| *Rebuilding and Preventing Overfishing: Finetooth Sharks* | | |
| D4. Identify sources of finetooth shark fishing mortality to target appropriate management actions | Same | Ongoing |
| *Rebuilding and Preventing Overfishing: Atlantic Billfish* | | |
| E3. Effective January 1, 2007, limit all Atlantic billfish tournament participants to using only non-offset circle hooks when using natural baits or natural bait/artificial lure combinations | E3. Effective January 1, 2007, limit all HMS permitted vessels participating in Atlantic billfish tournaments to deploying only non-offset circle hooks when using natural baits or natural bait/artificial lure combinations | January 1, 2007 |

| Preferred Alternative in Draft HMS FMP | Preferred Alternative in Final HMS FMP | Expected Implementation Date |
|---|---|---|
| E6. Effective January 1, 2007, implement ICCAT Recommendations on Recreational Marlin Landings Limits | Same | January 1, 2007 |
| E7. Effective January 1, 2007 - December 31, 2011, allow only catch and release fishing for Atlantic white marlin | No longer preferred | NA |
| *Management Program Structure: Bluefin Tuna Quota Management* | | |
| F3. Amend the management procedures regarding General category time-periods, subquota, as well as geographic set-asides to allow for future adjustments to take place via a regulatory framework action | Same | 30 days after final rule is published |
| F3(c). Revise General category time-periods and subquotas to allow for a formalized winter fishery (June-Aug, 50%; Sept, 26.5%; Oct-Nov, 13%; Dec, 5.2% and Jan, 5.3%) | Same | 30 days after final rule is published |
| F4. Clarify the procedures for calculating the Angling category school size-class BFT subquota allocation and remove the Angling category north/south dividing line | F4. Clarify the procedures for calculating the Angling category school size-class BFT subquota allocation and maintain the Angling category north/south dividing line | 30 days after final rule is published |
| F6. Revise the annual BFT specification process to refer back to the supporting analytical documents of the Consolidated HMS FMP and include seasonal management measures in annual framework actions | Same | 30 days after final rule is published |
| F8. Establish an individual quota category carry-over limit of 100 percent of the baseline allocation (*i.e.*, no more than the annual baseline allocation may be carried forward), except for the Reserve category, and authorize the transfer of quota exceeding the 100 percent limit to the Reserve or another domestic quota category, while maintaining status quo overharvest provisions | Same | 30 days after final rule is published |
| F10. Revise and consolidate criteria considered prior to performing inseason and some annual BFT management actions | Same | 30 days after final rule is published |
| *Management Program Structure: Timeframe for Annual Management of HMS Fisheries* | | |
| G2. Shift the fishing year to January 1 – December 31 for all HMS | Same | January 1, 2008 |
| *Management Program Structure: Authorized Fishing Gears* | | |
| H2. Authorize speargun fishing gear as a permissible gear type in the recreational Atlantic tuna fishery | H2. Authorize speargun fishing gear as a permissible gear type in the recreational Atlantic BAYS tuna fishery | 30 days after final rule is published |

| Preferred Alternative in Draft HMS FMP | Preferred Alternative in Final HMS FMP | Expected Implementation Date |
|---|---|---|
| H4. Authorize green-stick for the commercial harvest of Atlantic BAYS tunas | No longer preferred | NA |
| H5. Authorize buoy gear in the commercial swordfish handgear fishery, and limit vessels employing buoy gear to possessing and deploying no more than 35 individual buoys, with each having no more than two hooks or gangions attached | H5. Authorize buoy gear as a permissible gear type in the commercial swordfish handgear fishery; limit vessels employing buoy gear to possessing and deploying no more than 35 floatation devices, with each individual gear having no more than two hooks or gangions attached | 30 days after final rule is published |
| H7. Clarify the allowance of hand-held cockpit gears used at boat side for subduing HMS captured on authorized gears | Same | 30 days after final rule is published |
| *Management Program Structure: Regulatory Housekeeping* | | |
| I1(b). Establish additional restrictions on longline gear in HMS time/area closures by specifying a maximum and minimum allowable number of commercial fishing floats to qualify as a BLL and PLL vessel, respectively | No longer preferred | NA |
| I1(c). Differentiate between PLL and BLL gear based upon the species composition of the catch onboard or landed | Same | 30 days after final rule is published |
| I2(b). Require that the 2nd dorsal fin and the anal fin remain on all sharks through landing | Same | 30 days after final rule is published |
| I3(b). Add new prohibition at § 635.71(a)(48) making it illegal for any person to, "Purchase any HMS that was offloaded from an individual vessel in excess of the retention limits specified in §§ 635.23 and 635.24" | Same | 30 days after final rule is published |
| I3(c). Add new prohibition at § 635.71(a)(49) making it illegal for any person to, "Sell any HMS that was offloaded from an individual vessel in excess of the retention limits specified in §§ 635.23 and 635.24" | Same | 30 days after final rule is published |
| I4(b). Amend the second coordinate of the East Florida Coast closed area so that it corresponds with the EEZ | Same | 30 days after final rule is published |
| I5(b). Amend the definition of "handline" at § 635.2 by requiring that they be attached to, or in contact with, all vessels | Same | 30 days after final rule is published |
| I6(b). Prohibit vessels issued commercial permits and operating outside of a tournament from possessing, retaining, or taking Atlantic billfish from the management unit | Same | 30 days after final rule is published |

| Preferred Alternative in Draft HMS FMP | Preferred Alternative in Final HMS FMP | Expected Implementation Date |
|---|---|---|
| I7(b). Amend the HMS regulations to provide an option for Atlantic tunas dealers to submit required BFT reports using the Internet | Same | 30 days after final rule is published |
| I8(b). Require submission of “No Fishing” reporting forms for selected vessels if no fishing trips occurred during the preceding month, postmarked no later than seven days after the end of the month | Same | 30 days after final rule is published |
| I8(c). Require submission of the trip "Cost-Earnings” reporting form for selected vessels 30 days after a trip and the annual “Cost-Earning” report form by January 31 of each year | I8(c). Require submission of the trip “cost-earnings” reporting form for selected vessels 30 days after a trip, and the “annual expenditures” report form by the date specified on the form | 30 days after final rule is published |
| I9(b). Require vessel owners to report non-tournament recreational landings of North Atlantic swordfish and Atlantic billfish | I9(b). Require vessel owners (or their designees) to report non-tournament recreational landings of North Atlantic swordfish and Atlantic billfish | 30 days after final rule is published |
| I10(b). Modify the HMS regulations to state that “In addition, each year, 25 mt (ww) will be allocated for incidental catch by pelagic longlines” in the NED | I10(c). Conduct additional discussions at ICCAT regarding quota rollovers and adjust quotas allocated to account for bycatch related to pelagic longline fisheries in the vicinity of the management area boundary accordingly | 30 days after final rule is published |
| I11(b). Require recreational vessels with a Federal permit to abide by Federal regulations, regardless of where they are fishing, unless a state has more restrictive regulations | Same | 30 days after final rule is published |

*Bycatch Reduction: Workshops*

The June 2004 Biological Opinion (BiOp) for the Atlantic HMS pelagic longline fishery requires NMFS to conduct training workshops regarding the safe release and disentanglement of sea turtles from pelagic longline gear and to certify that fishermen have attended these workshops. The October 2003 BiOp on the Atlantic shark fishery requires a series of workshops that provide gear handling techniques and protocols that deal with entanglements and protected species, in general, and include information on smalltooth sawfish and HMS requirements. Additionally, in Amendment 1 to the Atlantic Tunas, Swordfish, and Shark FMP, NMFS stated that if shark fishermen can show that they can fish for specific species (*e.g.*, target sandbar sharks) and correctly identify the shark species caught on their gear, then the Agency might consider using species-specific shark quotas in the future. Thus, NMFS felt it was important to consider workshops, particularly workshops for handling and release of protected species and workshops for identification of Atlantic HMS, in this rulemaking.

The workshops for the safe release, disentanglement, and identification of protected resources are designed to reduce the post-hooking mortality of sea turtles and other protected resources by educating fishermen on how to apply the appropriate safe handling and release protocols, improve compliance with regulations, and enhance the utility of vessel logbook data. The preferred alternatives for the protected species workshops would require all longline and gillnet permit holders and operators to attend and be certified in handling and release techniques and gear. Mandatory workshops for vessel owners would be linked to the vessels' permit, ensuring well attended workshops. Including operators would guarantee at least one person on board the vessel during fishing activities is adept at the safe handling and release protocols. NMFS also considered a range of alternatives for the protected species workshops including voluntary workshops (no action) and mandatory workshops for the owners, operators, and the crew of all HMS longline and gillnet vessels.

The preferred alternative for the identification workshops calls for all Federally permitted shark dealers, or a designated proxy, to attend one-day workshops on species-specific identification of offloaded shark carcasses. NMFS believes that identifying shark carcasses is more difficult and uncertain than identifying other HMS carcasses as evidenced by the large proportion of "unclassified" sharks listed on shark dealer logbooks. This uncertainty compromises quota monitoring and stock assessment efforts. Dealers are a focal point for gathering shark landings information as sharks from numerous vessels are offloaded at each individual dealer. Positive identification is often less difficult for fishermen than dealers as they know exactly where (depth, type of habitat, etc) a shark has been caught and often see the sharks alive and intact. NMFS considered a range of alternatives for these identification workshops including voluntary HMS identification workshops for dealers, recreational fishermen, and all commercial vessel owners and operators (no action) and mandatory identification workshops for all HMS dealers and/or HMS permit holders.

Under the preferred alternatives, longline and gillnet permit holders and vessel operators and shark dealers would be required to be recertified every three years. NMFS also considered recertification time periods of two and five years. Requiring recertification every three years would balance the ecological benefits of maintaining familiarity with the protocols and the economic impacts of workshop attendance due to travel costs and lost fishing opportunities.

None of the preferred alternatives changed significantly between the draft and final stages of this HMS FMP, although NMFS did adjust the effective dates as a result of public comment and the lengthening of the comment period. These one-day workshops are not expected to result in excessive economic impacts as they would be scheduled at numerous locales along the Atlantic coast, minimizing travel and lost fishing time.

*Bycatch Reduction: Time/Area Closures*

Since the 1999 FMP for Atlantic Tunas, Swordfish, and Sharks, NMFS has implemented a number of time/area closures in order to reduce bycatch, to the extent practicable, consistent with the National Standards. While the results of preliminary analyses examining the efficacy of these closures have been included in annual SAFE Reports, a comprehensive analysis of the impact of the closures on bycatch rates, the fishermen, and the communities is contained in this document. In this document, NMFS examines the current time/area closures to determine if these closures are accomplishing the original goals of the closures and whether changes are needed to accomplish other objectives. The results of that examination indicate that both bycatch and overall effort in the fleet has been reduced (see discussions of alternative B1 in Chapter 4).

In this HMS FMP, NMFS is preferring two alternatives in regard to time/area closures. The first preferred alternative would establish HMS regulations in the Madison-Swanson and Steamboat Lumps Marine Reserves that complement the Gulf of Mexico Fishery Management Council's regulations. These closures are expected to have minimal ecological, economic, or social impacts on HMS fishermen. The second preferred alternative would establish criteria that would guide future decision-making regarding implementation or modification of time/area closures. This would provide enhanced transparency, predictability, and understanding of HMS management decisions, allow for more adaptive management, and should result in minimal social and economic impacts. Any impacts for specific closures would be analyzed when those closures are considered.

As described in Chapter 4 and Appendix A, NMFS used POP and HMS logbook data to identify new areas for time/area closures and selected alternatives based on these data to further analyze 10 different closures or modifications for this rulemaking. NMFS evaluated the reduction in discards of white marlin, blue marlin, sailfish, spearfish, leatherback sea turtles, loggerhead sea turtles, other sea turtles, and BFT without redistribution of effort based on POP data and the HMS logbook data for the various time/area closure alternatives (see Chapter 4). Using HMS logbook data (see Chapter 4 and Appendix A), NMFS evaluated different scenarios of a redistribution of fishing effort model, where each scenario had different assumptions regarding how fishing effort would be redistributed into open areas. The model used in this time/area analysis was consistent with the methods used in past rulemakings (for more information on redistribution of effort model selection, please see page 4-6). Additional redistribution of effort scenarios were considered based on comments received on the Draft Consolidated HMS FMP and the OMB reviews. As described in Chapter 4, each scenario of the models had different assumptions regarding how fishermen would react to the closures (*e.g.*, will fishermen move out of the closed area but continue fishing in surrounding open areas, move their business, or sell their permits to someone near an open area). Because of the difficulty in predicting fishermen's behavior, NMFS analyzed the range of what would happen fleet-wide while recognizing that individuals within the fleet may act differently, and large closures may result in more movement in order for fishermen to find open areas to fish and stay in business.

NMFS examined a wide range of alternatives including closing additional closures or combining these additional closures for pelagic longline gear in the Gulf of Mexico and the Atlantic Ocean, modifying existing closures for pelagic longline gear, establishing a closure for bottom longline gear to protect smalltooth sawfish, and closing all areas to pelagic longline gear. These alternatives were not preferred for a variety of reasons. The ecological benefits of some of the additional closure alternatives considered were predicted to be variable with redistribution of effort, with potential negative ecological impacts to several species. For example, alternative B2(a) (May - Nov), intended primarily to reduce leatherback sea turtle interactions, and white marlin and BFT discards, could result in a 7.9 percent increase in loggerhead sea turtle interactions and a 10.3 percent increase in BFT discards (see Table 4.2). As described in Appendix A, even the modified redistribution of effort model for alternative B2(a) predicted increases in sailfish discards (4.7 percent), LCS discards (4.4 percent), BFT discards (1.6 percent), and BAYS discards (0.7 percent). When closure areas were combined, the redistribution of effort model predicted similar results with an increase in discards of several species.

Alternatives B3(a) and B3(b) were considered to refine existing closures and to provide additional opportunity to harvest legal-sized swordfish while not increasing bycatch. NMFS, however, is not preferring any modifications to the current closures. None of the modifications considered would have resulted in a large enough increase in retained catch to alleviate concerns over uncaught portions of the swordfish and BFT quotas. For instance, B3(a) was predicted to increase retained swordfish catch by only 30.72 mt, and B3(a) was predicted to increase the retained swordfish catch by 0.07 mt. However, as of April 30, 2006, 4,905.9 mt and 294.7 mt of directed and incidental quota, respectively, were still available for the 2005 fishing year. In addition, modifications to existing closures could result in increased bycatch of blue and white marlin, which is a concern given the stock status of blue and white marlin and the scheduled white marlin ESA review. Increased interactions with sea turtles and marine mammals (*e.g.*, pilot whales and Risso's dolphins) are an additional concern.

Finally, all of these analyses (those analyzing the impacts of new closures and those analyzing the impacts of modifications to existing closures) were conducted using J-hook data. New circle hook management measures were put into place in 2004, and NMFS is still assessing the effects of circle hooks on bycatch rates for HMS. Based on the Northeast Distant experiment, circle hooks likely have a significantly different catch rate than J-hooks. Therefore, NMFS needs to conduct further investigations to determine the potential impact of any new time/area closures or modifications to existing closures. NMFS anticipates that 2005 HMS logbook final data will become available in the summer of 2006. In addition, NMFS is awaiting additional information regarding the status of the pelagic longline fleet after the devastating hurricanes in the Gulf of Mexico during the fall of 2005. A majority of the pelagic longline fleet was thought to be severely damaged or destroyed during the 2005 hurricane season. The amount of pelagic longline fishing effort, especially within the Gulf of Mexico, will likely be assessed in the summer of 2006 when 2005 HMS logbook final data becomes available. Until NMFS can better estimate the current fishing effort and potential recovery of the pelagic longline fleet, it may be premature to implement any new time/area closures, particularly in the Gulf of Mexico. Furthermore, a number of stock assessments will be conducted during 2006 (blue marlin, white marlin, north and south swordfish, eastern and western BFT, and large coastal sharks). NMFS is waiting on the results of these stock assessments to help determine domestic measures with regard to management of these species.

For the bottom longline closure alternative (B6), NMFS is waiting for the Smalltooth Sawfish Recovery Team to designate critical habitat in order to compare possible closure areas with the critical habitat. Closing all areas to pelagic longline gear (alternative B7) would have severe economic and social impacts in the short term and possible negative ecological impacts in the long term if U.S. quotas are transferred to countries without the same conservation ethic.

While NMFS did not change the preferred alternatives between the draft and final stages, NMFS did conduct additional analyses as a result of public comment. These analyses include examining the redistribution of effort model and its applicability, the mobility of the fleet, and the concept of a decision matrix. NMFS also began looking at the 2004 circle hook data for the pelagic longline fishery. In the future, NMFS intends, among other things, to investigate the choices fishermen have made regarding previous closures and to pursue alternatives to reduce bycatch in the Gulf of Mexico, especially for BFT. For BFT, NMFS is currently trying to assess how protecting one age class at the potential detriment of other age classes will affect the fish stock as a whole, and is also considering developing incentives that would dissuade fishermen from keeping incidentally caught BFT, particularly spawning BFT, in the Gulf of Mexico. This may involve research on how changes in fishing practices may help reduce bycatch of non-target species as well as the tracking of discards (dead and alive) by all gear types. More information on these additional analyses, their results, and potential future actions are contained in Chapter 4 and Appendix A.

*Rebuilding and Preventing Overfishing: Northern Albacore Tuna*

Since the 1999 FMP, NMFS has determined that northern albacore tuna are overfished. While NMFS published a final rule that stated NMFS would work with ICCAT to rebuild northern albacore, a rebuilding plan was not previously incorporated in the FMP. The preferred alternative would establish a foundation with ICCAT for developing an international rebuilding plan. Under this alternative, NMFS will continue to work with ICCAT member nations to develop and adopt an appropriate international rebuilding plan for northern albacore tuna with a specified recovery period, biomass targets, fishing mortality rate limits, and explicit interim milestones. The U.S. harvest of the North Atlantic stock is proportionally so low that the socio-economic impacts to the United States would likely be minimal but would depend upon the specifics of the rebuilding plan adopted by ICCAT. The other alternatives of no action or unilateral action would not be consistent with the Magnuson-Stevens Act or ATCA, and would be unlikely to rebuild northern albacore.

*Rebuilding and Preventing Overfishing: Finetooth Sharks*

In 2002, NMFS determined that overfishing is occurring on finetooth sharks. In the 2003 Amendment to the 1999 FMP, because most finetooth landings appear to come from fishermen in non-HMS fisheries, NMFS stated that it would take action to identify sources of fishing mortality on finetooth sharks, increase outreach, improve enforcement of the recreational limits, and work with the Regional Fishery Management Councils to identify fisheries that catch finetooth sharks.

In this HMS FMP, NMFS prefers an alternative that would establish a plan to prevent overfishing. This preferred alternative would identify the sources of fishing mortality for finetooth sharks. The analyses in the HMS FMP found that the majority of finetooth sharks are landed in the South Atlantic region (primarily Florida) by vessels deploying gillnet gear and in possession of both a Spanish mackerel permit and a commercial shark permit. NMFS also found that an unmanaged fishery, the southern kingfish fishery, also catches finetooth sharks. Thus, any management measures that are solely directed at fishermen using gillnet gear and in possession of a commercial shark permit could easily be circumvented by fishermen using gillnets for Spanish mackerel or kingfish. In addition to conducting analyses, NMFS has also contacted the states and Regional Fishery Management Councils, sent a letter to the South Atlantic Fishery Management Council requesting collaboration in management between gillnet fisheries, and requested that finetooth sharks be added to observer programs such as the Gulf of Mexico shrimp trawl fishery. These actions should provide additional options to address this issue.

NMFS considered other alternatives including no action, management measures targeting commercial shark permit holders, and management measures targeting recreational HMS permit holders. Targeting commercial shark permit holders is confounded by the fact that finetooth sharks are within the SCS complex, which is not currently overfished or experiencing overfishing, and commercial fishermen have only caught, on average, 28.5 percent of the SCS quota between 1999-2003. Measures aimed at the recreational fishery would only affect a small portion of the overall finetooth shark landings. Furthermore, a conservative bag limit of one shark (including finetooth shark) and a minimum size above the age at first maturity for males and females are already in place. NMFS intends to conduct a new small coastal shark stock assessment following the Southeast Assessment, Data, and Review process starting in 2007. As more research and data become available, NMFS may reconsider these other alternatives.

NMFS did not change the preferred alternative between the draft and final stages. NMFS believes that the preferred approach constitutes a plan to prevent overfishing and is a prudent means of establishing regulations that might affect a type of gear (gillnet), rather than an individual permit. Applying the regulations to the gear is critical as regulations implemented only on shark permit holders would only affect a sub-set of the individuals responsible for finetooth shark fishing mortality, could be easily circumvented, and would likely result in additional dead discards of finetooth sharks.

*Rebuilding and Preventing Overfishing: Atlantic Billfish*

Despite the implementation of domestic and international management measures, the status of Atlantic blue and white marlin has continued to decline. Currently, the status of sailfish and spearfish is uncertain. Atlantic white marlin has been identified as one of the most severely overfished species of any stock under ICCAT's purview for the past four years, but nevertheless continues to be subjected to unsustainable levels of fishing mortality throughout the Atlantic. In 2002, the United States undertook a status review of white marlin pursuant to the Endangered Species Act (ESA). While the status review team determined that white marlin stock status did not warrant a listing at that time, it concluded that "unless fishing mortality is reduced significantly and relatively quickly, the stock could decline to a level that would warrant ESA protection" (White Marlin Status Review Team 2002). NMFS will conduct another ESA listing review in 2007. As such, in this document, NMFS reviewed the current data and examined methods of reducing billfish mortality in both the commercial (*e.g.*, time/area closures) and recreational fisheries (*e.g.*, circle hook requirements).

NMFS is preferring two alternatives to reduce the post-release mortality of billfish associated with the directed billfish fishery. The first preferred alternative would require the use of non-offset circle hooks by HMS permitted vessels in billfish tournaments when using natural baits or natural bait/artificial lure combinations. The second preferred alternative would codify the ICCAT landings recommendations for billfish. The current landings recommendation would limit the United States to landing no more than 250 blue or white marlin per year. These alternatives strike a balance between conserving living marine resources and maintaining robust recreational fisheries while achieving the objectives of the HMS FMP. The preferred alternatives are anticipated to substantially reduce the post-release mortality of Atlantic white marlin, provide positive ecological benefits for other species such as blue marlin, sailfish, and tunas, and maintain consistency with United States' international obligations. NMFS is delaying the effective date for the circle hook requirement to mitigate, to the extent practicable, adverse economic impacts and losses in angler consumer surplus by allowing: tournament operators adequate time to adjust advertising, rules, business practices, and tournament formats; existing stockpiles of J-hooks to be used; and, anglers time to become comfortable and proficient with newly required gear.

As a result of public comment, NMFS is no longer preferring the alternative that would prohibit the landing of white marlin. Additionally, NMFS clarified the intent of the first preferred alternative to ensure that only HMS permit holders, not all tournament participants, would be affected by the circle hook requirement.

*Management Program Structure: Bluefin Tuna Quota Management*

Western Atlantic BFT are overfished, and one of the main objectives of the Consolidated HMS FMP is to end overfishing and rebuild overfished stocks, while providing reasonable fishing opportunities to harvest the limited quota that is available under the BFT rebuilding plan. Since the 1999 FMP, BFT management has become increasingly complicated and difficult for the public to understand and may no longer accurately reflect the needs of the fishery and goals of the 1999 FMP. These issues are evident on a daily basis from the number of constituent inquiries addressed by NMFS and the number of inseason management actions necessary throughout the season. In addition, NMFS has received a petition from the State of North Carolina Department of Marine Fisheries (NMDMF) for rulemaking to adjust the quota allocations to provide for a General category fishery off North Carolina in the winter. NMFS considers these requests and considers ways of clarifying BFT management.

Two of the preferred alternatives would amend the time period and sub quotas for the General category and clarify the procedures for calculating the Angling category school-size fish. These alternatives are expected to enhance NMFS' flexibility to address inherent variability in the BFT fishery while still allowing for business planning. They also respond in part to the NCDMF's Petition for Rulemaking and would allow for a formal General category winter BFT fishery while still recognizing the historical BFT catch rates in the New England area fishery. These preferred alternatives would also clarify the procedures NMFS used to implement the ICCAT recommendation regarding the eight percent tolerance limit of school BFT as well as maintain the recreational North/South dividing line as a management tool.

Two other preferred alternatives would provide participants in the BFT fishery a timely and stable baseline quota allocation from one year to the next, the ability to address under/overharvest from the previous year, the ability to establish the General category effort controls as well as recreational and commercial handgear daily retention limits for the upcoming season, and streamline the annual rulemaking process. Additionally, providing NMFS the authority to implement a cap on the amount of quota that may be carried forward from one fishing year to the next would allow NMFS to manage to harvest of BFT with more finite precision and minimize the occurrence of 'stockpiling' in any one quota category.

Another preferred alternative would consolidate and refine the criteria that NMFS must consider prior to conducting any inseason, and some annual, actions. This preferred alternative would assist in meeting the Consolidated HMS FMP’s objectives in a consistent manner, providing reasonable fishing opportunities, increasing the transparency in the decision making process, and balancing the resource's needs with users’ needs.

*Management Program Structure: Timeframe for Annual Management of HMS Fisheries*

In the 1999 FMP and 1999 Billfish Amendment, NMFS established a fishing year management cycle for tunas, billfish, and swordfish that began on June 1 and went through the following May 31. This fishing year was established to allow NMFS time to implement recommendations from ICCAT before the fishing year began. The change to the fishing year, however, has been problematic given that many of the data infrastructure and reporting requirements both within NMFS and ICCAT are based on a calendar year rather than a fishing year. NMFS prefers the alternative that would establish a fishing year management cycle for all HMS of January 1 through December 31. This preferred alternative is expected to simplify the regulatory process for constituents in the long term by managing all HMS fisheries on a calendar year and improve the United States’ basis for negotiation at international forums.

*Management Program Structure: Authorized Fishing Gears*

In 1999, NMFS published a list of authorized gears for all fisheries across the nation. Occasionally, NMFS receives requests to modify the list of authorized gears. Sometimes, these requests include gear that fishermen use in other oceans or elsewhere in the Atlantic to catch the same species; other times, the requests are due to additional groups requesting to use a gear that is approved for one permit, but not another. NMFS considers some of these requests (*e.g.*, green-stick gear and speargun fishing gear) pertaining to HMS in this rulemaking.

NMFS prefers several alternatives that would add authorized gear types in HMS fisheries. The first preferred alternative would allow spearfishermen to participate in the Atlantic bigeye, albacore, yellowfin, and skipjack (BAYS) tunas fishery. This alternative is responsive to specific public comment and requests from constituents. This preferred alternative is anticipated to result in minimal negative ecological impacts and positive social and economic benefits. This preferred alternative is modified slightly from what was proposed in that, due to concerns related to the status of BFT, only BAYS tunas could be taken by spearfishermen, not BFT.

The second preferred alternative would allow the commercial swordfish handgear fishery to continue to utilize individual unattached buoyed gears (a.k.a. buoy gear), and would limit the maximum number of gears deployed by a vessel. Before this FMP, both recreational and commercial swordfish handgear fishermen could use this gear, previously called handline, and were not limited in the number of gears that could be deployed. This alternative may provide some positive ecological benefits by limiting future expansion of this gear sector and possibly by reducing the amount of lost fishing gear. This alternative could result in positive social benefits and would maintain current economic benefits to this sector. The last preferred alternative would, in response to requests from fishery participants, clarify the allowable use of secondary cockpit gears. This alternative should not result in an increase in bycatch mortality, over current levels, as secondary gears are currently utilized in HMS fisheries.

Although NMFS originally preferred an alternative that would allow for the use of greenstick in the commercial BAYS fishery in the Draft HMS FMP, it is not preferred in the Final HMS FMP. During the comment period, NMFS realized that many fishermen, both commercial and recreational, did not understand which gear configurations were currently allowed and which configurations the Agency was proposing to allow. Thus, NMFS will clarify the existing regulatory regime and the allowable configurations of green-stick gear in an effort to reduce confusion regarding the authorized use of green-stick gear.

*Management Program Structure: Regulatory Housekeeping*

This rulemaking also considers a number of corrections and additions to the Atlantic HMS regulations at 50 CFR part 635 and other relevant sections in the CFR (*e.g.*, 50 CFR part 300 contains information regarding international trade) in order to clarify their intent, remove incorrect cross-references, remove dated regulations, as appropriate, and aid enforcement. Besides the more than 40 minor corrections to the regulatory text, NMFS also considered a few changes that required alternatives. In all, NMFS is preferring 13 alternatives in this section across a wide range of eleven different issues.

The first issue in this section pertains to the definitions of bottom and pelagic longline gear. These gears catch different species and are currently differentiated by the number of weights and/or floats each gear uses. This raises enforcement concerns particularly in closed areas. As such, NMFS is preferring an alternative that would differentiate between gears based upon the species composition of the catch onboard or offloaded. This alternative is expected to accommodate the majority of commercial fishing operations, yet still provide a quantifiable method to differentiate between vessels using one gear or the other. Vessels that fish mixed trips (*i.e.*, trips that use both gear types) could still transit the closed areas provided the signals from their vessel monitoring system unit indicate the vessel is transiting and not fishing. This alternative is not expected to create significant adverse economic and social impacts and is expected to improve the monitoring of, and compliance with, HMS closed area regulations. NMFS originally preferred both the current preferred alternative and an alternative that would limit the number of floats on bottom longline vessels. NMFS is no longer preferring that alternative based upon public comment regarding impacts to vessel's operational flexibility, difficulties with terminology, and impracticalities in enforcing the alternative. Other alternatives considered, besides the no action, included requiring time and depth recorders and closing all areas to "longline" rather than trying to define the gears.

The second issue pertains to shark identification. Currently, shark fishermen may remove all fins from the shark, consistent with the five-percent shark fin ratio. NMFS prefers an alternative that would require the second dorsal and anal fins to remain on all sharks through the first port of landing. While this alternative could have some minor economic and social impacts, this alterative is expected to generate ecological benefits by enhancing and improving species identification and data collection, thereby leading to improved management and increased shark populations. NMFS also considered alternatives that would allow fishermen to remove the second dorsal and anal fins from some species (*e.g.*, lemon sharks) or require all fins to remain on the shark.

In a third issue regarding sales of illegal landings, NMFS is preferring two alternatives that would add clear prohibitions to the regulations regarding the sale and purchase of landings in excess of the commercial retention limits. These alternatives may act as an additional deterrent to discourage this illegal practice. NMFS believes that the social benefits of preventing this practice should outweigh any short-term economic benefit gained as a result of illegally selling catches in excess of the commercial retention limits.

In a fourth issue regarding the definition of the closed areas, NMFS is preferring an alternative that would amend the area of the East Florida Coast closed area by extending one of its coordinates 1.02 km (0.55 nmi) seaward so that it corresponds with the outer boundary of the exclusive economic zone (EEZ). This alternative is not expected to create significant adverse economic and social impacts. Any fishing effort that would have occurred in this area would likely relocate to nearby open areas with similar catch rates. Because the East Florida Coast closed area would be enlarged under this alternative, it could reduce the bycatch of undersized swordfish, sailfish, and other HMS as compared with the no action alternative, but this reduction is expected to be minimal.

The fifth issue pertains to the definition of handline. In the authorized fishing gear section of the HMS FMP, NMFS is preferring an alternative that would define unattached handlines as buoy gear and restrict their use to commercial swordfish fishermen. In this section, NMFS is preferring an alternative that would require that handlines remain attached to all vessels. This alternative would primarily affect recreational fishery participants and commercial permittees that do not possess a commercial swordfish handgear permit. This alternative is not expected to have significant adverse social or economic impacts on fishery participants.

The sixth issue described in this section pertains to the retention of billfish by commercial permit holders. The directed billfish fishery is a recreational fishery. The regulations before this FMP required that all pelagic longline fishermen release any billfish. The regulations were silent on the retention of billfish by other commercial fishermen. NMFS is preferring an alternative that would clarify the regulations and would allow only recreational and charter/headboat fishermen to retain Alantic billfish. General category permit holders participating in a registered HMS tournament could retain billfish during the tournament. Charter/headboat fishermen who also hold commercial permits (*e.g.*, shark limited access permit) could retain billfish on non-for hire fishing trips only if no HMS on board exceed the recreational limits.

The seventh issue pertains to BFT dealer reports. The preferred alternative would provide an option for BFT dealers to submit certain reports electronically over the Internet once such a system is developed, but would not require it. Although unquantifiable, this alternative is expected to produce positive social and economic impacts for both industry and government, as a result of timesavings incurred when such a system is developed.

The eighth and ninth issues are related to reporting. The preferred alternatives would require no fishing reports and cost-earning reports to be submitted within a certain timeframe and would require either vessel owners or their designee, rather than anglers, to report all non-tournament recreational landings of Atlantic billfish and North Atlantic swordfish. None of these alternatives are expected to have adverse social or economic impacts. Rather, they clarify the regulations and improve data collection.

The tenth issue addresses the Northeast Distant (NED) BFT set-aside for pelagic longline fishermen. NMFS is preferring the alternative that would conduct additional discussions at ICCAT regarding the long-term implications of allowing unused BFT quota from the previous year being added to the subsequent year's allocation. Depending on the results of these discussions the regulations and operation procedures may need to be further amended in the future. In the interim, NMFS would maintain the current regulatory text, but would amend the practice of allowing under/overharvest of this set-aside allocation to be rolled into, or deducted from, the subsequent fishing year's set-aside allocation. This alternative would allow the pelagic longline fishery to retain incidentally caught BFT in the NED to the amount of 25 mt (ww) before landings are counted against the overall Longline category quota. At the proposed stage, NMFS preferred the alternative that would amend the current regulatory text and allow unharvested set-aside quota to be carried forward to subsequent years. That alternative is no longer preferred due to concerns about stockpiling quota and creating potential incentives to target BFT.

The last issue addressed in this section pertains to the inconsistencies between state and Federal regulations. Under the regulations, commercial swordfish and shark fishermen, as a condition of their permit, must abide by Federal regulations when fishing in state waters unless the state has more restrictive regulations. NMFS is preferring an alternative that would expand this permit condition to recreational and charter/headboat fishermen. This alternative is expected to achieve increased consistency between state and Federal regulations for Federally-permitted HMS recreational fishermen, and result in less confusion on behalf of fishermen and improved compliance. Compared with the No Action alternative, the preferred alternative would produce greater ecological benefits with few adverse social and economic impacts.

*Essential Fish Habitat*

In addition, this Consolidated HMS FMP continues a five-year review of EFH consistent with the EFH guidelines. The Magnuson-Stevens Act requires the Secretary, through NMFS, to establish guidelines to assist in the description and identification of EFH in FMPs, among other things.  The Agency set forth a schedule for the review and update of such EFH identifications based on new scientific evidence or other relevant information.  The EFH guidelines articulate processes for determining the extent of EFH for each species and life-stage in a managed fishery. In addition, the EFH guidelines call for periodic review and revision of EFH identified areas based on available information, as well as a complete review of all EFH information at least once every five years.  NMFS originally described and identified EFH for all HMS in 1999, and recently updated the EFH for five shark species (blacktip, dusky, finetooth, nurse, and sandbar) in Amendment 1 to the FMP for Atlantic Tunas, Swordfish, and Sharks, which was finalized in 2003.  In this document, NMFS includes the information available for all HMS in order to aid in the determination of which species need updates to their EFH identifications.  Any updates or resulting changes in management will be done in a future document.

*Future Considerations*

Beyond the issues addressed in this document or raised during scoping, other new and unresolved matters have been identified by the general public, the HMS and Billfish Advisory Panels, and NMFS staff as important to rebuilding and maintaining fisheries that are economically and biologically sustainable.  NMFS may consider these issues or others in future rulemakings.  It is important to note that some of these additional issues are complicated, may require specific comments from the public for development (*e.g.*, scoping meetings and/or developmental workshops), and may take several years to complete.  These issues include: the BFT fishery (status of BFT, protection of spawning grounds, potential impact of herring fisheries, size limits, filleting at sea); the swordfish fishery (quota underharvests, reporting by recreational anglers, limited access restrictions, time/area closures); the billfish fishery (ESA status review in 2007, stock status, reduction in bycatch and post-release mortality); the shark fishery (new stock assessments, changes to trip limits, limited access restrictions, time/area closures); HMS permit reform; and recordkeeping, reporting, and monitoring of all HMS fisheries.  These issues are described in more detail in Section 1.5.

# CHAPTER 1 TABLE OF CONTENTS

## CHAPTER 1 LIST OF TABLES

# 1.0 INTRODUCTION

Atlantic Highly Migratory Species (HMS)[1] are managed under the dual authority of the Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act) and the Atlantic Tunas Convention Act (ATCA). Under the Magnuson-Stevens Act, the National Marine Fisheries Service (NMFS) must, consistent with the National Standards, manage fisheries to maintain optimum yield (OY) by rebuilding overfished fisheries and preventing overfishing. Under ATCA, NMFS is authorized to promulgate regulations, as may be necessary and appropriate, to implement the recommendations from the International Commission for the Conservation of Atlantic Tunas (ICCAT). Additionally, any management measures must also be consistent with other domestic laws including, but not limited to, the National Environmental Policy Act (NEPA), the Endangered Species Act (ESA), the Marine Mammal Protection Act (MMPA), and the Coastal Zone Management Act (CZMA).

Before this document, Atlantic tunas, swordfish, and sharks were managed under the 1999 Fishery Management Plan (FMP) for Atlantic Tunas, Swordfish, and Sharks (and its 2003 amendment) and Atlantic billfish were managed under the 1988 Atlantic Billfish FMP (and its 1999 amendment). This final document consolidates the management of all Atlantic HMS into one comprehensive FMP (described Section 1.4), and combines and simplifies the objectives of the previous FMPs (described in Section 1.3).

Chapters 2 and 4 of this document provide a description of the alternatives and the analyses of the potential impacts. All of the preferred alternatives would likely be implemented in a final rule to be published shortly after this document. Chapter 3 provides a description of the fishery and contains the 2006 stock assessment and fishery evaluation report (SAFE report). Chapter 5 discusses any mitigating measures regarding the alternatives. Chapters 6, 7, and 8 fully analyze the economic impacts of the alternatives and address the requirements of a Regulatory Impact Review (RIR) and Final Regulatory Flexibility Analysis (FRFA). Chapter 9 provides the social impact analysis. Chapter 10 describes the first step in updating the descriptions of essential fish habitat. Appendix A provides the methodologies and analyses for the time/area closure alternatives described in Sections 2.1.2 and 4.1.2. Appendix B provides the maps for EFH as described in Chapter 10. Appendix C provides additional information related to domestic Atlantic billfish mortality contributions of the recreational sector and the pelagic longline fishery. Appendix D provides a summary of the comments received on the draft HMS FMP and proposed rule and NMFS' responses. Appendix E provides the peer reviews completed under the OMB peer review bulletin and NMFS' actions based on those reviews.

[1] The Magnuson-Stevens Act, at 16 U.S.C. 1802(14), defines the term "highly migratory species" as tuna species, marlin (*Tetrapturus* spp. and *Makaira* spp.), oceanic sharks, sailfishes (*Istiophorus* spp.), and swordfish (*Xiphias gladius*). Further, the Magnuson-Stevens Act, at 16 U.S.C. 1802(27), defines the term "tuna species" as albacore tuna (*Thunnus alalunga*), bigeye tuna (*Thunnus obesus*), bluefin tuna (*Thunnus thynnus*), skipjack tuna (*Katsuwonus pelamis*), and yellowfin tuna (*Thunnus albacares*).

## 1.1 Brief Management History

This section provides a brief overview of the major influences regarding HMS management and the existing FMPs. More detail regarding the management history of HMS can be found in Section 3.1.

In the 1980s, the Regional Fishery Management Councils were responsible for the management of Atlantic HMS. Thus, in 1985 and 1988, the five Councils finalized joint FMPs for swordfish and billfish, respectively. In 1989, the Councils requested that the Secretary of Commerce (Secretary) manage Atlantic sharks. NMFS finalized a Shark FMP in 1993. Atlantic tunas did not have an FMP until 1999.

On November 28, 1990, the President of the United States signed into law the Fishery Conservation Amendments of 1990 (Pub. L. 101-627). This law amended the Magnuson Fishery Conservation and Management Act (later renamed the Magnuson-Stevens Fishery Conservation and Management Act or Magnuson-Stevens Act) and gave the Secretary the authority (effective January 1, 1992) to manage HMS in the exclusive economic zone (EEZ) of the Atlantic Ocean, Gulf of Mexico, and Caribbean Sea under authority of the Magnuson-Stevens Act (16 U.S.C. §1811). This law also transferred from the Fishery Management Councils to the Secretary, effective November 28, 1990, the management authority for HMS in the Atlantic Ocean, Gulf of Mexico, and Caribbean Sea (16 U.S.C. §1854(f)(3)). The Secretary then delegated authority to manage Atlantic HMS to NMFS. In 1992, the HMS Management Division was created within NMFS to manage Atlantic HMS.

Under the Magnuson-Stevens Act, NMFS must maintain OY of each fishery by preventing overfishing and rebuilding overfished stocks. To do this, NMFS must, among other things, consider the National Standards, including using the best scientific information and considering impacts on residents of different States, efficiency, costs, fishing communities, bycatch, and safety at sea (16 U.S.C. §1851 (a)(1-10)). The Magnuson-Stevens Act also has a specific section that addresses preparing and implementing FMPs for Atlantic HMS (16 U.S.C. §1854 (g)(1)(A-G)). In summary, the section includes, but is not limited to, requirements to:

- Consult with and consider the views of affected Councils, Commissions, and advisory groups;
- Evaluate the likely effects of conservation and management measures on participants and minimize, to the extent practicable, any disadvantage to U.S. fishermen in relation to foreign competitors;
- Provide fishing vessels with a reasonable opportunity to harvest any allocation or quota authorized under an international fishery agreement;
- Diligently pursue comparable international fishery management measures; and,
- Ensure that conservation and management measures promote international conservation of the affected fishery, take into consideration traditional fishing patterns of fishing vessels, are fair and equitable in allocating fishing privileges among U.S. fishermen and do not have economic allocation as the sole purpose, and promote, to the extent practicable, implementation of scientific research programs that include the tagging and release of Atlantic HMS.

In addition to domestic management under the Magnuson-Stevens Act, Atlantic HMS are also managed internationally by ICCAT. ICCAT consists of 42 contracting parties as well as other cooperating parties that fish for tunas and tuna-like species throughout the Atlantic including Canada, the European Community, Japan, and China. Since 1966, ICCAT's stated objective has been to "cooperate in maintaining the populations of these fishes at levels which will permit the maximum sustainable catch for food and other purposes." To achieve this objective, ICCAT requires countries to collect catch data. In 1966, through a resolution, ICCAT urged all countries to begin to collect and process statistics and data on Atlantic tunas fisheries. In 1972, noting data deficiencies, ICCAT again urged countries to improve the collection and efficiency of Atlantic tunas catch-effort data and to make sure data are made available to ICCAT. These types of requests continue to be made, either as resolutions or recommendations, as the management and science needs for each fishery continue to expand.

The current conservation and management recommendations of ICCAT include total allowable catches, sharing arrangements for member countries, minimum size limits, effort controls, time/area closures, trade measures, compliance measures, and monitoring and inspection programs. If the United States accepts an ICCAT recommendation, ATCA provides the Secretary with the necessary statutory authority to issue regulations as may be necessary and appropriate to implement binding ICCAT recommendations to fisheries managed by the United States (16 U.S.C. §971 *et seq*.). However, no regulation promulgated under ATCA may have the effect of increasing or decreasing any allocation or quota of fish or fishing mortality level to which the United States agreed pursuant to a recommendation of ICCAT (16 U.S.C. §971 (c)). ICCAT recommendations can be found on the internet at http://www.ICCAT.es .

In 1999, due in part to amendments to the Magnuson-Stevens Act in 1996 and additional information regarding the status of several Atlantic HMS, NMFS combined the FMPs for Atlantic swordfish and sharks and finalized the first FMP for Atlantic tunas. The result was the FMP for Atlantic Tunas, Swordfish, and Sharks (1999 FMP). At this time, NMFS also amended the 1988 Billfish FMP. Since 1999, NMFS has changed a number of regulations either through framework actions, regulatory amendments, or FMP amendments. This includes, but is not limited to, implementation of time/area closures, implementation of gear requirements for pelagic longline fishery or gear, implementation of vessel monitoring systems for shark and pelagic longline fisheries, changes in retention limits, changes in permitting requirements for charter/headboat and recreational fishermen, handling and release gear requirements for non-target species (bycatch) in longline fisheries, and changes in reporting requirements for recreational fishermen. Additionally, the status of some Atlantic HMS has changed, the pelagic longline fishery has received several times determinations that the continuation of the fishery without additional actions could jeopardize the existence of certain sea turtles, and the swordfish and bluefin tuna fisheries are not currently catching their quotas. Thus, HMS fisheries, as described in the 1999 FMP and the 1999 Billfish Amendment, have changed.

## 1.2 Need for Action

As described above, since 1999, the regulations for HMS fisheries have changed for a variety of reasons. As such, the 1999 FMP and Amendment may no longer fully describe the current fisheries. The changes have been documented in the supporting documents for various rulemakings and in annual SAFE reports. However, this document represents the first time since

1999 that a majority of the HMS fisheries have been impacted in one rulemaking. These changes and the inclusiveness of this document have been a challenge. Both before and during scoping, the public and NOAA staff raised a number of management issues that merit additional consideration and examination. Some of these issues require an FMP amendment. Other issues would be more appropriately and efficiently addressed in conjunction with other regulatory actions. However, in order to complete action on some of the issues identified during the scoping process in a timely manner, NMFS decided to handle only a portion of them in this rulemaking. NMFS prioritized the issues and chose to consider those in this rulemaking that were required by law (*e.g.*, handling and release workshops are required under the 2004 Biological Opinion) and/or would improve the management or the fisheries (*e.g.*, amending the FMP for the bluefin tuna General Category should allow management to match changes in the fisheries on a more timely basis). Other issues will be considered, as appropriate, in future rulemakings (see Section 1.5). This section provides a succinct summary of some of the reasons for the management measures being considered in this rulemaking. More detail on the individual issues can be found in Chapters 2 and 4.

This section also describes the actions that are amending the FMP and the actions that are considered regulatory framework adjustments or actions under the FMP (Table 1.1). A framework action includes notice and comment rulemaking and amends implementing regulations but not the FMP itself. Both the 1999 FMP and the 1999 Billfish Amendment listed certain management measures that could be adjusted via framework action to meet the objectives of the FMP and the Magnuson-Stevens Act and that would not necessarily require amending the FMP (50 CFR §635.34). This list was modified with Amendment 1 to the 1999 FMP. The actions preferred in this document span a range of framework actions and amendments to the FMP. The list of the types of management actions that can be accomplished via a framework action is provided in Chapter 11 of this document. For more information regarding the differences between framework actions and FMP amendments, please see Chapter 3 of the 1999 Atlantic Tunas, Swordfish, and Shark FMP.

**Table 1.1 Table indicating whether actions in this document are amending the FMP or are being taken as framework actions.**

| Major Issue | Framework or FMP Amendment |
|---|---|
| Reducing Bycatch: Workshops | FMP Amendment |
| Reducing Bycatch: Time/area closures | FMP Amendment and framework action |
| Rebuilding: Northern albacore tuna | FMP Amendment |
| Overfishing: Finetooth sharks | FMP Amendment |
| Rebuilding: Billfish | Framework action |
| Management Program: Bluefin tuna | FMP Amendment and framework action |
| Management Program: Timeframe for Annual Management | Framework action |
| Management Program: Authorized gears | Framework action |
| Management Program: Regulatory housekeeping | Framework action |

The June 2004 Biological Opinion (BiOp) requires NMFS to conduct training workshops regarding the release of sea turtles from pelagic longline gear and to certify that fishermen have attended these workshops. The October 2003 BiOp requires a series of workshops that provide gear handling techniques and protocols that deal with entanglements and protected species, in general, and including information on smalltooth sawfish and HMS requirements. Additionally, in Amendment 1 to the 1999 FMP, NMFS stated that if shark fishermen can show that they can correctly identify shark species and fish for specific species, then the Agency might consider using species-specific shark quotas in the future. In public comments received during the scoping period and on the Predraft, some fishermen commented that the data collection problem is not with the fishermen but with the dealers who often incorrectly identify shark species. These comments were considered when analyzing alternatives for workshops. Many of the needs for workshops and certifying that people are trained to handle and release fish or protected resources and to identify certain species are beyond what was considered in the 1999 FMP and Billfish Amendment. Thus, in this document, NMFS amends the 1999 FMP and Billfish Amendment and examines different types of workshops to meet these needs.

Since 1999, NMFS has implemented a number of time/area closures in order to reduce bycatch, to the extent practicable, consistent with National Standard 9. While preliminary analyses have been done in annual SAFE reports that examine the efficacy of these closures, a comprehensive analysis of the impact of the closures on bycatch rates, the fishermen, and the communities is contained in this document. Based on the results of this comprehensive analysis, in this rulemaking, NMFS examines the current time/area closures to determine if these closures are accomplishing the original goals of the closures or if changes are needed. NMFS also examines the need for additional closures to reduce bycatch in HMS fisheries of certain species including sea turtles, white marlin, and bluefin tuna. The 1999 FMP considered and allowed for the implementation of time/area closures as framework actions. However, in this action NMFS is considering a comprehensive mechanism regarding how to analyze the need for establishing, modifying, or removing time/area closures. Because this alternative is beyond the scope of the 1999 FMP, the preferred alternatives in this document recommend both amending the 1999 FMP and implementing closures under the framework mechanism.

Since the 1999 FMP, NMFS has determined that overfishing is occurring on finetooth sharks and that northern albacore tuna are overfished. NMFS addresses rebuilding and overfishing for these species in this action. For northern albacore tuna, because its rebuilding plan is not yet outlined in the FMP, any actions being considered would be an amendment to the FMP. Finetooth sharks do not require a rebuilding plan because they are not overfished but action is required to prevent overfishing. Because the actions being considered to address overfishing are contained in the list of framework actions (see Chapter 11), the actions being considered to address overfishing of finetooth sharks would be regulatory framework actions.

Despite the implementation of domestic and international management measures, the status of Atlantic blue and white marlin has continued to decline. Currently, the status of sailfish and spearfish is uncertain. Atlantic white marlin has been identified as one of the most severely overfished species of any stock under ICCAT's purview for the past four years, but nevertheless continues to be subjected to unsustainable levels of fishing mortality throughout the Atlantic. In 2002, the United States undertook a status review of white marlin pursuant to the ESA. While the status review team determined that white marlin stock status did not warrant a listing at that time, it concluded that "unless fishing mortality is reduced significantly and relatively quickly, the stock could decline to a level that would warrant ESA protection" (White Marlin Status Review Team 2002). NMFS is will conduct another ESA listing review in 2007. Ultimately, the declines in the status of blue and white marlin have diminished the likelihood of achieving domestic rebuilding goals and objectives outlined in the 1999 Billfish Amendment.

The United States has led billfish conservation efforts internationally over the past decade. The effects of these efforts, while serving to move conservation forward in the policy arena, are as yet uncertain from a biological perspective. Additional information on this issue should be available in mid to late 2006 when the next ICCAT stock assessment for Atlantic marlin is finalized. While the United States cannot unilaterally reverse stock declines for these species given the international nature of the fishery, additional domestic management actions are possible and appropriate to augment steps that have thus far been unable to stem long-term downward population trends and/or increasing fishing mortality rates for Atlantic marlins. Failure of the United States to continue leading international efforts to rebuild marlin will likely result in this issue losing visibility and priority among international fishery managers, as marlin are generally taken incidental to directed fishing activities for more commercially valuable species. The rulemaking process and the management measures analyzed are a critical component of demonstrating such leadership. Reinforcing the need for action are new data suggesting that post-release mortality for white marlin from recreational catch-and-release fishing with traditional J-hooks may be considerably higher than previous estimates. New data and studies also indicate that in some years, the domestic recreational billfish fishery may be responsible for an equal or greater amount of billfish mortality than the domestic pelagic longline fishery, in some years. This appears to be the result of the significant size differential between the two fisheries. As such, in this document, NMFS reviews the current data and examines methods of reducing billfish mortality in both the commercial (*e.g.*, time/area closures) and recreational fisheries (*e.g.*, minimum sizes, circle hooks). Because the management measures specific to reducing billfish fishing mortality are being considered are within the scope of those allowed for framework actions, these measures would be taken as regulatory framework actions.

Over the years, BFT management has become increasingly complicated, and may no longer accurately reflect the needs of the fishery and goals of the 1999 FMP. These issues are evident on a daily basis from the number of constituent inquiries addressed by NMFS and the number of inseason management actions necessary throughout the season. In addition, NMFS has received a petition from the State of North Carolina for rulemaking to adjust the quota allocations to provide for a General category fishery off of North Carolina in the winter. NMFS is considering these requests and is also considering ways of clarifying BFT management. Some of the changes considered are within the scope of those that the 1999 FMP stated could be accomplished by framework actions. However, other alternatives are beyond the scope of a framework action and need to be accomplished by FMP amendment. Thus, this issue encompasses both framework actions and amendments to the FMP.

In the 1999 FMP and Billfish Amendment, NMFS established a fishing year for tunas, billfish, and swordfish that began on June 1 and went through the following May 31. This fishing year was established to allow NMFS time to implement recommendations from ICCAT before the fishing year began. The change to the fishing year, however, has been problematic given that many of the data infrastructures and reporting requirements both within the Agency and ICCAT are based on calendar year rather than fishing years. Thus, NMFS revisits this issue during this rulemaking. Changes to the fishing year are within the scope allowed in the 1999 FMP and the 1999 Billfish Amendment. Thus, this issue is being taken as a framework action.

In 1999, NMFS published a list of authorized gears for all fisheries across the nation. Occasionally, NMFS receives requests to modify the list of authorized gears. Sometimes, these requests include gear that fishermen use in other oceans or elsewhere in the Atlantic to catch the same species; other times, the requests are due to additional groups requesting to use a gear that is approved for one permit, but not another. NMFS considers some of these requests pertaining to HMS, such as greenstick and speargun fishing gear, in this FMP. The use and restriction of gears is within the scope of management measures that can be modified through framework actions; thus, any changes to the authorized gears would be achieved via a framework action.

This FMP also considers a number of corrections and additions to the Atlantic HMS regulations at 50 CFR part 635 and other relevant sections in the CFR (*e.g.*, 50 CFR part 300 contains information regarding international trade) in order to clarify their intent, remove incorrect cross-references, remove dated regulations, as appropriate, and aid enforcement. These actions are all being taken as framework actions.

In addition, this consolidated HMS FMP continues the five-year review of HMS EFH consistent with the EFH guidelines. The Magnuson-Stevens Act requires the Secretary, through NMFS, to establish guidelines to assist in the description and identification of EFH in FMPs, among other things. The Agency set forth a schedule for the review and update of such EFH identifications based on new scientific evidence or other relevant information. The EFH guidelines articulate processes for determining the extent of EFH that encompasses each species and life-stage in a managed fishery. In addition, the EFH guidelines call for periodic review and revision of EFH identified areas based on available information, as well as a complete review of all EFH information at least once every five years. NMFS originally described and identified EFH for all HMS, including Atlantic billfish, in 1999, and recently updated the EFH for five shark species (blacktip, dusky, finetooth, nurse, and sandbar) in Amendment 1 to the FMP for Atlantic Tunas, Swordfish, and Sharks, which was finalized in 2003. In this document, NMFS includes the information available for all HMS, including billfish, in order to aid in the determination of which species need updates to their EFH identifications. Any updates or resulting changes in management will be done in a future document.

## 1.3 Objectives

Consistent with the consolidated FMP objectives (see Section 1.4.4) and the National Standards, the specific objectives of this action are to:

- Better coordinate domestic conservation and management of the fisheries for Atlantic tunas, swordfish, sharks, and billfish, considering the multi-species nature of many HMS fisheries;
- Simplify management of Atlantic HMS, to the extent practicable;
- Update the ecological, economic, and social data regarding HMS fisheries;

- Reduce bycatch and bycatch mortality, to the extent practicable, while also minimizing the economic and social impacts on related fisheries;
- Reduce mortality, including dead discards and post-release mortality, to the extent practicable, of Atlantic HMS in directed and non-directed fisheries;
- Improve, to the extent practicable, data collections or data collection programs;
- Implement, to the extent practicable, the bycatch reduction strategy using the standardized bycatch reduction methodology; and,
- Begin the review process for updating EFH identifications for Atlantic HMS, as needed.

## 1.4 Combining Management for Atlantic HMS

As discussed above, NMFS issued two separate documents in April 1999 for the Atlantic HMS fisheries. The 1999 Fishery Management Plan for Atlantic Tunas, Swordfish, and Sharks, combined, amended, and replaced previous management plans for swordfish and sharks, and was the first FMP for tunas. Amendment 1 to the Billfish Management Plan updated and amended the 1988 Billfish FMP.

In 1999, based on concerns expressed by Advisory Panel (AP) members about consolidating the FMPs for billfish and the other HMS, as well as the recreational nature of the domestic billfish fishery, NMFS chose to maintain separate FMPs and APs for these species. Nevertheless, over the past six years that these two FMPs have co-existed, there has been a growing recognition by NMFS of the interrelated nature of these fisheries and the need to consider management actions together. In addition, NMFS has identified some adverse ramifications stemming from separation of the plans, including unnecessary administrative redundancy and complexity, loss of efficiency, and public confusion over the management process. The following examples illustrate the closely intertwined nature of the fisheries and their management:

1. The Magnuson-Stevens Act defines highly migratory species as tuna species, marlin, oceanic sharks, sailfishes, and swordfish;
2. An HMS Angling or Charter/Headboat (CHB) permit is required to fish for billfish or other HMS recreationally;
3. Recreational fishermen target billfish and other HMS in the same season and often on the same trip;
4. Recreational fishermen can use rod and reel to fish for both billfish and other HMS;
5. Many of the primary management actions for addressing overfishing and bycatch issues for billfish are contained in the 1999 FMP for Atlantic Tunas, Swordfish, and Sharks;
6. Any potential management measures for billfish or other HMS are likely to impact the same communities;
7. The reporting requirements for billfish and other HMS fishermen overlap;

8. The regulations for Atlantic billfish and the other Atlantic HMS are all contained in 50 CFR part 635; and,
9. The Billfish and HMS Advisory Panels usually meet in a combined session[2].

As such, consistent with the fifth objective of Billfish Amendment 1[3] and the ninth objective listed in the 1999 Tunas, Swordfish, and Sharks FMP[4], NMFS is consolidating these FMPs into one comprehensive FMP to improve coordination of the conservation and management of the domestic fisheries for Atlantic swordfish, tunas, sharks, and billfish. The regulatory implications of consolidating the FMPs are negligible, as the regulations governing the fisheries for all Atlantic HMS have been consolidated in 50 CFR part 635 since 1999.

During the comment periods on the Predraft and Draft, some HMS and Billfish AP members, some Council members, and many recreational billfish fishermen objected to the consolidation of the FMPs. For the most part, they were concerned that: (1) two objectives from the 1988 Billfish FMP were identified for removal, on the basis that their core intent was thought to be adequately contained in objectives that would remain (this was a concern raised only for the Predraft); (2) commercial fisheries aim to utilize the specific quota while recreational fisheries, particularly billfish fisheries, aim to have the highest abundance of fish available because they are predominantly catch-and-release fisheries; (3) in a consolidated FMP, billfish would be considered only as a bycatch species and would not be a priority; and (4) billfish would lose representation on the AP. As a result of the first comment, NMFS kept those two objectives as they were originally drafted in the consolidated HMS FMP (Section 1.3). Regarding the second comment, NMFS agrees that commercial fishermen aim to fully utilize a quota and many recreational fishermen practice catch-and-release fishing. NMFS believes that this difference can be accommodated in a consolidated FMP just as they already are in the existing tunas, swordfish, and shark fisheries that are both commercial and recreational. Further, given the interconnected nature of the billfish fishery with other HMS fisheries, both on the water and in the regulatory and policy arenas, as well as the current permitting structure, changes in any of the non-billfish fisheries are likely to have impacts on the billfish fishery. Combining the FMPs would allow those changes to be analyzed more holistically with clearer links among the impacts and issues between fisheries. Regarding the third comment, NMFS believes that combining the FMPs will not change the priorities of managing HMS, which are dictated by the Magnuson-Stevens Act and other domestic law. Regarding the fourth comment, the composition of the APs in terms of representation by states and sectors (commercial, recreational, academic, or conservation) would not change as a result of combining the plans (Section 1.4.3).

Another group of constituents, including AP and Council members, objected to combining the FMPs because they felt that too many species and too much information had

[2] The Advisory Panels have met separately five times since their creation in 1997 (out of approximately 14 AP meetings total). In 1997, the Billfish AP met twice without the HMS AP because the HMS AP had not yet been created (July 7, 1997, 62 FR 36261; September 3, 1997, 62 FR 46483). At its first meeting, the HMS AP met alone (October 9, 1997, 62 FR 52692) and again after a joint meeting to discuss shark issues (July 20, 1998, 63 FR 38808). In 2003, the HMS AP met to discuss the proposed Amendment 1 to the 1999 FMP (August 27, 2003, 68 FR 51560).

[3] To better coordinate domestic conservation and management of the fisheries for Atlantic tunas, swordfish, sharks, and billfish, considering the multispecies nature of many highly migratory species (HMS) fisheries, overlapping regional and individual participation, international management concerns, and other relevant factors.

[4] To better coordinate domestic conservation and management of the fisheries for Atlantic tuna, swordfish, sharks, and billfish, considering the multispecies nature of many HMS fisheries, overlapping regional and individual participation, international management concerns, historical fishing patterns and participation, and other relevant factors.

already been combined in the existing FMPs. If anything, these parties felt that the species and management measures in the existing FMPs should be separated and that NMFS should manage on a more species-specific basis. NMFS believes that combining the FMPs for tunas, swordfish, and sharks, and the actual regulations for all HMS has led to a more holistic view of the fishery. This view has allowed the impacts of management measures on all sectors of HMS fisheries to be fully analyzed whereas before, the links may not have been seen or analyzed as readily. By combining the FMPs, NMFS is moving toward an ecosystem-based approach to the management of HMS. Such an approach could ultimately benefit the resource and the people involved. As an example, at several of the meetings on the Predraft, fishermen have noted that using circle hooks while trolling for blue marlin is impracticable. At those same meetings, tuna fishermen asked for the use of circle hooks on rod and reel. In many cases, the same fishermen fish for tunas and billfish. While NMFS could implement different regulations for tunas and billfish, more effective and appropriate management can only be done by considering the implications on both fisheries.

NMFS also received comments that other interested parties, including some recreational fishermen and AP members, feel the plan to consolidate the FMPs makes sense and is only logical, particularly given the overlapping nature of the fisheries. Some people, who supported the consolidation, noted that the customary joint meetings of the HMS and Billfish APs have resulted in an imbalance of representation favoring the recreational fishing sector. NMFS does not believe that the current APs are imbalanced. Combining the FMPs will not change the composition of the APs; however, NMFS may change the composition over time in order to preserve the balance between different interest groups.

A summary of all the comments received on the draft HMS FMP and NMFS' responses can be found in Appendix D.

### 1.4.1 Implications for Management Measures

The 1999 Tunas, Swordfish, and Sharks FMP integrated and replaced preexisting management measures for Atlantic tuna, swordfish, and shark fisheries. Amendment 1 to the Billfish FMP (1999) was developed in coordination with the Tunas, Swordfish, and Sharks FMP, but augmented rather than replaced the preexisting Billfish FMP, which had been finalized in 1988. The consolidated HMS FMP is intended to augment and combine the 1999 Atlantic Tunas, Swordfish, and Sharks FMP, Amendment 1 to the 1999 Atlantic Tunas, Swordfish, and Sharks FMP, the 1988 Billfish FMP, and Amendment 1 to the Billfish FMP into a single fishery management plan. To reiterate, upon issuance of this final document, there will be a single management plan for Atlantic tunas, swordfish, sharks, and billfish. Under this consolidated HMS FMP, "HMS" includes billfish in all references except where noted otherwise.

The consolidation itself would not change any existing management measures for Atlantic tunas, swordfish, sharks, and billfish that have been issued previously under the authority of ATCA and the Magnuson-Stevens Act. Neither would the consolidation change any of the threshold criteria that are used to determine the status of the stock (*e.g.*, overfishing is occurring if $F_{year}>F_{MSY}$). These threshold criteria are summarized briefly in Section 3.2. Should NMFS determine that further changes are necessary to the regulations or the threshold criteria, they will be made through the FMP amendment process or through rulemaking as described in the framework provisions. Please see below (Section 1.4.4) for a discussion of the implications of combining the plans on the plan objectives.

### 1.4.2 Implications for the Exemption to the Billfish No Sale Provision

The 1988 Fishery Management Plan for Atlantic Billfish prohibited the sale or purchase of Atlantic billfish. Recognizing the existence of a traditional artisanal handline fishery in Puerto Rico that occasionally landed billfishes, primarily blue marlin, the 1988 Billfish FMP also included a limited exemption from the “no sale” provision to accommodate this fishery. The exemption to the “no sale” provision was subject to a number of conditions and restrictions, including:

- only fish caught on handlines having fewer than six hooks could be retained for sale;
- vessels retaining billfish for sale could not have a rod and reel onboard;
- fish could be sold only in Puerto Rico;
- a maximum of 100 billfish per year could be landed and sold;
- if more than 100 billfish per year were landed under the exemption, the Councils would consider removing the exemption;
- all existing fishermen wishing to sell billfish would be required to obtain a permit;
- the Caribbean Fishery Management Council, in cooperation with the Government of the Commonwealth of Puerto Rico, would develop and implement a system for tracking billfish landings under the exemption; and,
- The exemption would not be in effect until the permitting and tracking systems were operative, pending approval by the five involved Councils at that time.

The exemption from the “no sale” provision for the Puerto Rican handline artisanal fishery has never been implemented under Federal regulations, because the aforementioned conditions have never been met, either prior to or following transfer of the FMP to Secretarial authority. Given that Atlantic billfish are overfished, overfishing continues to occur, longlines (not handlines) are defined in 50 CFR part 635 as having three or more hooks, and non-fulfillment of conditions necessary to implement the exemption over nearly two decades, NMFS sought comment on the potential removal of the “no sale” exemption from the FMP during the scoping process for this document. Further, as the provision was developed and approved by the five Atlantic Fishery Management Councils prior to transfer of the FMP to Secretarial authority, NMFS specifically sought comment from the Regional Fishery Management Councils on this issue in November 2004.

Public comment on elimination of the exemption to the no sale provision as discussed in the Predraft document was mixed, with support for its elimination as well as limited support for maintaining the exemption. In response to direct outreach efforts to the Councils on this issue, NMFS received formal responses from the New England Council, the Mid-Atlantic Council, and the Caribbean Council. The New England Council responded with a formal “no comment” on the issue, as it had not been directly involved in HMS management issues since the inception of

Secretarial Authority. The Mid-Atlantic Council indicated that removal of the exemption was an appropriate action, and the Caribbean Council adopted a formal motion at its May 2005 meeting in St. Thomas, USVI, in support of removing the provision. At the draft stage, NMFS did not receive any comments in opposition to the removal of this exemption.

Based on the status of Atlantic billfish as overfished with continuing overfishing; non-fulfillment of the conditions necessary to implement the exemption to the no sale provision and resultant non-implementation of the provision over a period of 18 years; public comment at all stages of writing this document; and, support of the involved Regional Fishery Management Councils, specifically the Caribbean Council which would be most directly impacted by the potential elimination of the exemption provision, NMFS is not carrying forward the exemption to the no sale provision for the artisanal handline fishery in Puerto Rico into this final consolidated HMS FMP.

### 1.4.3 Implications for Highly Migratory Species and Billfish Advisory Panels

The HMS and Billfish Advisory Panels (AP) were established in 1997, pursuant to Magnuson-Stevens Act requirements (16 U.S.C. 1801 et. seq., as amended by the Sustainable Fisheries Act PL 104-297), to assist NMFS in the collection and evaluation of information relevant to the development of the 1999 Tunas, Swordfish, and Sharks FMP and Amendment 1 of the Billfish FMP. Nominations for initial membership on the APs were solicited in March and August of 1997 for the Billfish and HMS APs, respectively. The first meeting of the Billfish AP was in July 1997 and the first meeting of the HMS AP was in October 1997.

Membership for both panels is composed of representatives of the commercial and recreational fishing communities, as well as conservation and academic interests. When finalizing the members on each panel, NMFS attempts to achieve a balance among sectors, regions, and species. The five Regional Fishery Management Councils involved in Atlantic HMS management, the Atlantic and Gulf Coastal States, the U.S. Coast Guard, and the U.S. ICCAT Advisory Committee have *ex-officio* seats. In keeping with operating practices for appointments to Regional Fishery Management Councils, in recent years, appointments to the 24-member HMS AP have been selected on a staggered, three-year cycle with eight members appointed for a three-year term. For the Billfish AP, which consists of nine appointed members, terms are on a two-year cycle with four members appointed for each two-year term. Staggered terms were implemented to ensure that there is some institutional memory on the APs at all times. The terms of *ex-officio* seats do not expire and assignment and substitution of these AP representatives are at their discretion of the respective agencies.

With the consolidation of the APs under this FMP, NMFS expects to revise the AP standard operating procedures. With this revision, NMFS will consider, among other things, how long the terms of AP members should be. The terms of current AP members will not change as a result of this consolidation.

Composition of the existing HMS and Billfish APs, in terms of the number of seats and the percentage of seat allocation, is detailed in Table 1.2. With the completion of the FMP consolidation process, the memberships of the two panels will be combined into a single consolidated HMS AP that will advise NMFS on all HMS issues, including billfish. NMFS will continue to balance representation based on species, sector, and regions, as necessary. Thus, the numbers presented in Table 1.2 may change over time, as needed.

**Table 1.2 Current Advisory Panel Seat Allocation.**

| | Current HMS AP | | Current Billfish AP | | Combined AP | |
|---|---|---|---|---|---|---|
| | # of Seats | % Representation | # of Seats | % Representation | # of Seats | % Representation |
| Commercial | 10 | 42 | 2 | 22.2 | 12 | 36.3 |
| Recreational | 8 | 33 | 4 | 44.4 | 12 | 36.3 |
| Conservation | 4 | 17 | 1 | 11.1 | 5 | 15.1 |
| Academic | 2 | 8 | 2 | 22.2 | 4 | 12.1 |
| Totals | 24 | 100 | 9 | 100 | 33 | 100 |

### 1.4.4 Implications for the FMP Objectives

Amendment and consolidation of the 1999 Tunas, Swordfish, and Shark and the Billfish FMPs and their amendments provides an opportunity to review the suitability and relevance of the HMS and Billfish FMP objectives. Both plans contain a detailed set of objectives, of which many overlap, complement, or otherwise reinforce each other. At the same time, a small number of objectives are unique to each plan, and may not logically apply to the other plan. NMFS has identified changes to the objectives of the previous FMPs that will remove redundancy and update some objectives. The objectives are finalized as outlined in Table 1.3.

**Table 1.3 Previous and Final Objectives of the Atlantic Tunas, Swordfish, and Shark, Billfish, and Consolidated HMS FMPs. *Italicized* text indicates the differences in objectives between the two previous FMPs.**

| Obj. # | Tunas, Swordfish, and Shark FMP | Billfish FMP and Billfish Amendment | Final Consolidated FMP |
|---|---|---|---|
| 1 | To prevent or end overfishing of *Atlantic tuna, swordfish, and sharks* and adopt the precautionary approach to fishery management | Prevent and/or end overfishing of Atlantic *billfish* and adopt the precautionary approach to fishery management | Prevent or end overfishing of Atlantic tuna, swordfish, billfish, and sharks and adopt the precautionary approach to fishery management |
| 2 | To rebuild overfished fisheries *in as short a time as possible* and control all components of fishing mortality, both directed and incidental, so as to ensure the long-term sustainability of the stocks and promote stock *recovery of the management unit* to the level at which the maximum sustainable yield can be supported on a continuing basis | Rebuild overfished *Atlantic billfish stocks, and monitor* and control all components of fishing mortality, both directed and incidental, so as to ensure the long-term sustainability of the stocks and promote *Atlantic-wide stock recovery* to the level where MSY can be supported on a continuing basis | Rebuild overfished Atlantic HMS stocks, and monitor and control all components of fishing mortality, both directed and incidental, so as to ensure the long-term sustainability of the stocks and promote Atlantic-wide stock recovery to the level where MSY can be supported on a continuing basis |

| Obj. # | Tunas, Swordfish, and Shark FMP | Billfish FMP and Billfish Amendment | Final Consolidated FMP |
|---|---|---|---|
| 3 | To minimize, to the extent practicable, *bycatch of living marine resources and the mortality of such bycatch that cannot be avoided in the fisheries for Atlantic tuna, swordfish, and sharks* | Minimize, to the extent practicable, *release mortality in the directed billfish fishery, and minimize, to the extent practicable, bycatch and discard mortality of billfish on gears used in other fisheries* | Minimize, to the extent practicable, bycatch of living marine resources and the mortality of such bycatch that cannot be avoided in the fisheries for Atlantic HMS or other species, and minimize, to the extent practicable, post-release mortality in the directed billfish fishery |
| 4 | To establish a foundation for *international negotiation on* conservation and management measures to rebuild overfished fisheries and to promote achievement of optimum yield for these species throughout their range, both within and beyond the exclusive economic zone. *Optimum yield is the maximum sustainable yield from the fishery, reduced by any relevant social, economic, or ecological factors* | Establish a foundation for *the adoption of comparable international* conservation and management measures, *through international entities such as ICCAT*, to rebuild overfished fisheries and to promote achievement of optimum yield for these species throughout their range, both within and beyond the EEZ | Establish a foundation for international negotiation on conservation and management measures, through international entities such as ICCAT, to rebuild overfished fisheries and to promote achievement of optimum yield for these species throughout their range, both within and beyond the exclusive economic zone |
| 5 | To minimize, to the extent practicable, economic *displacement and other adverse impacts on fishing communities during the transition from overfished fisheries to healthy ones* | Minimize *adverse social and economic effects on recreational and commercial activities* to the extent practicable, *consistent with ensuring achievement of the other objectives of this plan, and with all applicable laws* | Minimize, to the extent practicable, adverse social and economic impacts on fishing communities and recreational and commercial activities during the transition from overfished fisheries to healthy ones, consistent with ensuring achievement of the other objectives of this plan and with all applicable laws |
| 6 | To provide the data necessary for assessing the fish stocks and managing the fisheries, including addressing inadequacies in *current* collection and ongoing collection of social, economic, and bycatch data *about HMS* fisheries | Provide the data necessary for assessing the fish stocks and managing the fisheries, including addressing inadequacies in collection and ongoing collection of social, economic, and bycatch data *on Atlantic billfish* fisheries | Provide the data necessary for assessing the fish stocks and managing the fisheries, including addressing inadequacies in current collection and ongoing collection of social, economic, and bycatch data on Atlantic HMS fisheries |

| Obj. # | Tunas, Swordfish, and Shark FMP | Billfish FMP and Billfish Amendment | Final Consolidated FMP |
|---|---|---|---|
| 7 | Consistent with other objectives of this FMP, to manage Atlantic HMS fisheries for continuing optimum yield so as to provide the greatest overall benefit to the Nation, particularly with respect to *food production, providing* recreational opportunities, *preserving traditional fisheries*, and taking into account the protection of marine ecosystems | Consistent with other objectives of this *amendment*, manage Atlantic billfish fisheries for the continuing optimum yield so as to provide the greatest overall benefit to the Nation, particularly with respect to recreational opportunities and taking into account the protection of marine ecosystems. *Optimum yield is the maximum sustainable yield from the fishery, as reduced by any relevant social, economic, or ecological factors.* | Consistent with other objectives of this FMP, manage Atlantic HMS fisheries for continuing optimum yield so as to provide the greatest overall benefit to the Nation, particularly with respect to providing food production for commercial fisheries, enhancing recreational opportunities, preserving traditional fisheries to the extent practicable, and/or taking into account the protection of marine ecosystems |
| 8 | To better coordinate domestic conservation and management of the fisheries for Atlantic tuna, swordfish, sharks, and billfish, considering the multispecies nature of many HMS fisheries, overlapping regional and individual participation, international management concerns, *historical fishing patterns and participation*, and other relevant factors | Better coordinate domestic conservation and management of the fisheries for Atlantic tunas, swordfish, sharks, and billfish, considering the multispecies nature of many highly migratory species (HMS) fisheries, overlapping regional and individual participation, international management concerns, and other relevant factors | Better coordinate domestic conservation and management of the fisheries for Atlantic tuna, swordfish, sharks, and billfish, considering the multispecies nature of many HMS fisheries, overlapping regional and individual participation, international management concerns, historical fishing patterns and participation, and other relevant factors |
| 9 | *To provide a framework, consistent with other applicable law, to take necessary action under ICCAT compliance recommendation* | *Coordinate domestic regulations and ICCAT conservation measures for controlling Atlantic-wide fishing mortality* | Provide a framework, consistent with other applicable law, to take necessary action under ICCAT compliance and/or conservation recommendations, including controlling Atlantic-wide fishing mortality |
| 10 | To *promote* protection of areas identified as essential fish habitat for *tuna, swordfish, and sharks* | *Maximize* protection of areas identified as essential fish habitat for *Atlantic billfish, particularly for critical life stages* | Promote conservation and enhancement of areas identified as essential fish habitat for Atlantic HMS, particularly for critical life stages |
| 11 | To simplify and streamline HMS management while actively seeking input from affected constituencies, the general public, and the HMS AP | | Simplify and streamline HMS management while actively seeking input from affected constituencies, the general public, and the HMS AP |

| Obj. # | Tunas, Swordfish, and Shark FMP | Billfish FMP and Billfish Amendment | Final Consolidated FMP |
|---|---|---|---|
| 12 | | Promote the live release of Atlantic *billfish* through active outreach and educational programs | Promote the live release and tagging of Atlantic HMS that are voluntarily released or cannot be legally landed through active outreach and educational programs |
| 13 | | Maintain the highest availability of billfishes to the U.S. recreational fishery by implementing conservation measures that will reduce fishing mortality | Maintain the highest availability of billfishes to the U.S. recreational fishery by implementing conservation measures that will reduce fishing mortality |
| 14 | | Optimize the social and economic benefits to the nation by reserving the billfish resource for its traditional use, which in the continental United States is almost entirely a recreational fishery | Optimize the social and economic benefits to the nation by reserving the Atlantic billfish resource for its traditional use, which in the United States is entirely a recreational fishery |
| 15 | | Increase understanding of the condition of billfish stocks and the billfish fishery | Increase understanding of the condition of HMS stocks and HMS fisheries |
| 16 | To reduce latent effort and overcapitalization in HMS commercial fisheries | | Delete. |
| 17 | To create a management system to make fleet capacity commensurate with resource status so as to achieve the dual goals of economic efficiency and biological conservation | | Consistent with the other objectives of this FMP, create a management system to make fleet capacity commensurate with resource status so as to improve both economic efficiency and biological conservation, and provide access for traditional gears and fishermen |
| 18 | To develop eligibility criteria for participation in the commercial shark and swordfish fisheries based on historical participation, including access for traditional swordfish handgear fishermen to participate fully as the stock recovers | | Combined with objective 17. |

## 1.5 Issues for Future Consideration and Outlook

Beyond the issues addressed and raised in this document, other new and unresolved matters have been identified by the general public, the HMS and Billfish Advisory Panels, and

NOAA staff as important to rebuilding and maintaining fisheries that are economically and biologically sustainable. Some of the main issues are identified below. This list is not comprehensive in nature, and NMFS may consider these issues or others in future rulemakings, possibly through framework actions. The issues are not listed in any priority. It is important to note that some of the issues are complicated, may require specific comments from the public for development (*e.g.*, scoping meetings and/or developmental workshops), and may take several years to complete.

- Bluefin Tuna Fishery Issues

During this rulemaking, NMFS heard many comments regarding the BFT fishery in general. There is growing concern regarding the status of BFT, protection of the spawning grounds in the Gulf of Mexico, the underharvests in recent years, overlap between the BFT and herring fisheries/habitat, and the current minimum size and trip limits. Purse Seine participants also continue to request changes to the current regulations that limit Purse Seine vessel landings of large medium bluefin tuna (73 inches to less than 81 inches) to no more than 15 percent, by weight, of the total amount of giant bluefin tuna landed during a fishing year. Angling category participants have concerns about the unit of measurement used by surveyors and the amount of quota available in their category. Charter/headboat fishermen continue to request the ability to fillet tunas at sea. Also, ICCAT is conducting a stock assessment in June 2006 that should provide additional information regarding the status of BFT and the current rebuilding plan. It is likely that in November 2006 ICCAT will finalize the stock assessment and recommend management actions for BFT. While NMFS cannot predict what the recommendation(s) will contain, many of the actions taken in this HMS FMP should help NMFS implement the new recommendations. For example, the time/area closure preferred alternative to implement criteria for the consideration of additional or modified closures for any gear type in order to protect BFT, if needed. NMFS may also consider closing an area of the Gulf of Mexico and opening it as an experimental fishery to test for ways of reducing bycatch of spawning bluefin tuna through such things as hook and bait combinations, environmental conditions, and/or temporal and spatial associations among different species. Also, amending the process to establish the General Category subperiod and subquotas could facilitate adjustments in a more timely manner, if necessary. Depending on ICCAT recommendation(s) and the status of BFT, it is possible that NMFS could include additional issues within an ICCAT implementation rule. However, NMFS will need to prioritize issues to ensure that international obligations are met and the rebuilding plan is progressing.

- Swordfish Fishery Issues

For the past several years, the domestic swordfish fishery has been unable to catch its full U.S. quota allocation. This is a change from the fishery in the 1990s where the quota was usually taken. In 1997, the quota was overharvested and the fishery was closed. There are a number of possible explanations and factors that may contribute to the inability of the domestic fleet to fully harvest the swordfish quota today including time/area closures to pelagic longline gear (the primary gear used to harvest swordfish), the reduction in permit holders through limited access, the restrictions on vessel upgrading, the incidental trip limits, the few number of swordfish reported landed by the recreational sector, and other economic factors (*e.g.*, fuel cost). Given the general anticipation that the North Atlantic swordfish stock will be identified as fully rebuilt, per the pending September 2006 stock assessment, a number of fishermen and others have asked NMFS to assist in revitalizing this fishery. Options that have been raised include, but are not limited to, opening the time/area closures, allowing open access to swordfish handgear permits, removing or modifying the upgrade restrictions, removing or modifying the incidental trip limits, and improving recreational reporting. Many people are concerned that without a plan to revitalize the fishery, the quota will be taken from the United States and given to other countries, many of which appear to place a lower priority on conservation than does the United States. NMFS is also concerned about the status of this fishery and the U.S. quota. While this rulemaking was not intended to revitalize the swordfish fishery, many of the preferred alternatives would facilitate future actions. For example, NMFS did not modify any existing closures at this time but the preferred criteria would allow for modifications to the closed areas and/or experiments to test gears or other fishing methods in the closed areas. Additionally, NMFS is defining a "new" swordfish commercial gear type (*i.e.*, buoy gear) and clarifying the difference between this commercial gear and the primarily recreational gear of handline. Depending on the stock assessment, the takes of sea turtles and marine mammals by the pelagic longline fleet, the recommendations of the final Pelagic Longline Take Reduction Plan, and the upcoming ICCAT recommendations, NMFS expects to do rulemaking in the near future to aid in revitalizing the swordfish fishery. Such a rulemaking could, but may not necessarily, reconsider the time/area closures using the criteria established in this FMP and using circle hook data, consider changes to the upgrading restrictions and incidental trip limits, and modifications to the permitting program (described more below). Revitalizing this fishery may also require additional assistance such as creation of a Seafood Marketing Council (January 24, 2006, 71 FR 3797). Other factors that NMFS cannot control, such as fuel prices or the cost to upgrade vessels, may impact the revitalization effort. Over time, consistent with the objectives of this FMP, the Magnuson-Stevens Act, MMPA, and the ESA, NMFS intends to aid in revitalizing the fishery so that swordfish are harvested in a sustainable and economically viable manner and bycatch is minimized to the extent practicable.

- Billfish Fishery Issues

Blue and white marlin are overfished and overfishing is occurring. However, the United States is responsible for a small portion of the mortality compared to other countries in the Atlantic. NMFS received a petition under the ESA to list white marlin and intends to conduct a status review in 2007. Additionally, while Atlantic billfish cannot be sold, Pacific billfish can be. Thus, NMFS has a number of challenges to address regarding the billfish fishery and stock, much of which will depend on the results of the May 2006 stock assessment. In recent years, NMFS has implemented a number of time/area closures that have reduced the bycatch of billfish in the pelagic longline fishery. In this rulemaking, NMFS has considered several time/area closures in part to continue to reduce bycatch of billfish in the pelagic longline fishery. NMFS did not find a time/area closure that would reduce both billfish bycatch and bycatch of other species; however, the criteria could allow NMFS to continue considering this option based on circle hook data. In this rulemaking, NMFS also considered several alternatives that could reduce the post-release mortality of billfish in the directed recreational fishery. NMFS is preferring some of those alternatives and has analyzed alternatives that may, or may not, be considered by ICCAT in November 2006. NMFS is also closing potential loopholes for billfish mortality by limiting the landings or possession of billfish to Angling and Charter/Headboat category permit holders and to General category permit holders who are participating in a tournament. Regardless of the permit combination (*e.g.*, Charter/Headboat and commercial shark limited access permit), no billfish may be possessed or retained on board vessels that have commercial quantities of other HMS on board. Depending on the recommendations by ICCAT in November 2006, the results of the 2006 stock assessment, and other priorities, NMFS may need to initiate a rulemaking regarding billfish in the near future. As part of this rulemaking, NMFS may consider standardized reporting requirements, particularly in regard to the Certificate of Eligibility (COE) for Pacific billfish. Such a step may improve compliance, facilitate enforcement, and improve the quality and quantity of information on Atlantic billfish harvest and Pacific billfish shipments.

- Shark Fishery Issues

Since initiation of the 2003 Amendment 1 to the 1999 Atlantic Tunas, Swordfish, and Shark FMP, there have been a number of new assessments and new information relating to sharks. ICCAT assessed blue and shortfin mako sharks in 2004. In 2004, Canada began considering listing porbeagle sharks as endangered under Canadian laws based on a 2001 stock assessment, and in 2005, Canada published an updated stock assessment for porbeagle sharks. Both fishermen and environmentalists have requested NMFS to lower the porbeagle shark quota and strengthen the regulations in response. In August 2005, the Atlantic States Marine Fisheries Commission agreed to develop a coast-wide shark fishery management plan for state waters. In October 2005, NMFS began the process to update the LCS stock assessment; this assessment should be done in 2006. Also in 2005, the Mid-Atlantic Fishery Management Council requested jurisdiction to manage smooth dogfish. NMFS has also conducted a species-specific stock assessment for dusky sharks that is undergoing internal review. NMFS expects to update the SCS stock assessment starting in early 2007. Based on these many stock assessments and changes, NMFS realizes there may be a need to adjust current quotas for certain species. Besides this information, public comments have continued to raise concerns over particular management measures. Thus, future rulemaking may also consider, as needed, other modifications including, but not limited to, the mid-Atlantic time/area closure, changes to the LCS trip limit, changes to the upgrading restrictions and/or incidental trip limits, changes to the prohibited species list, reporting for recreational fishermen, changes to authorized gear, and changes to the management unit. Additionally, in early 2006, a right whale calf was found dead with gillnet lacerations. Thus, the gillnet fishery in the right whale critical habitat was closed for the last part of the calving season through March 31, 2006 (February 16, 2006, 71 FR 8223). The Office of Protected Resources is currently considering this issue in light of the Marine Mammal Protection Act and the Atlantic Large Whale Take Reduction Plan. Given this and repeated requests by the State of Georgia and others, NMFS may need to conduct a rulemaking to reconsider the use of gillnet gear in Atlantic shark fisheries.

- HMS Permit Reform

In the 1990s, NMFS issued shark and swordfish permits that were essentially species-based but also allowed fishermen to catch tunas other than non-bluefin tuna. NMFS also issued bluefin tuna permits that were established by gear type. In 1999, NMFS established a limited access permit system for tuna longline, swordfish, and sharks. Since then, NMFS has also implemented two overarching permits for those fishermen fishing for any HMS: angling and charter/headboat. Thus, fishermen fishing for HMS now have a variety of required permits to choose from, some of which are species-based and some of which are gear-based. Once the fisherman chooses to use one particular required permit, the fisherman must fish for that species with the particular gear authorized by that permit (*i.e.*, they are placed in a box). This has caused concern and has raised a number of complicated questions and answers. Thus, NMFS intends to conduct a rulemaking regarding HMS permits that could include, among other things, further rationalizing some segments of the HMS fisheries, streamlining or simplifying the permitting process, restructuring the permit program (gear-based, species-based, or both), reopening some segments of the limited access system to allow for the issuance of additional permits, modifying when permits are renewed (fishing year or birth month), and considering dedicated access privileges (*e.g.*, individual transferable permits).

- Recordkeeping, Reporting, and Monitoring

Timely and reliable data is critical for fishery management. Thus, NMFS is always striving to improve its data collection. Data for HMS fisheries is collected in a number of ways including through self-reported methods, such as logbooks or call-in systems, and through observers. Observer data are generally considered to be of higher quality; however, observer programs are expensive to operate and the majority of fishing effort is conducted without observers. Recent Biological Opinions pertaining to HMS fisheries require NMFS to collect observer information specific to sea turtles and marine mammals on pelagic longline vessels and commercial vessels participating in the Atlantic shark fisheries. Observer data collection in other HMS fisheries, including the recreational and Charter/Headboat fisheries, is voluntary at this time. Commercial fishermen in some HMS fisheries are required to submit logbooks. Many fishermen have asked for electronic or real-time reporting. Similarly, HMS dealers must submit dealer reports and many of them have asked for electronic reporting.

NMFS also collects commercial fisheries data via vessel monitoring systems (VMS). In HMS, pelagic longline, bottom longline, and gillnet fishermen are all required to use VMS during certain seasons. All VMS units need to be turned on and operating two hours before the vessel leaves port until the vessel returns to port. NMFS and fishermen have had problems with VMS not operating while the vessel is away from port. Some VMS units do not have any indicator light or other method for fishermen to see if the unit is working. Fishermen have also commented that certain brands appear to be unreliable. NMFS enforcement has indicated that hourly reporting may not be frequent enough for all of their needs.

Recreational fisheries are a major component of Atlantic HMS fisheries, and because recreational landings of Atlantic HMS are not marketed through commercial channels, it is not possible to monitor anglers' catches through ex-vessel transactions as in the commercial fishery. Instead, NMFS collects data through other means including the two primary statistical sampling surveys of the recreational fisheries: the Marine Recreational Fishery Statistics Survey (MRFSS) and the Large Pelagics Survey (LPS). Both surveys consist of a telephone survey to estimate effort and a dockside intercept program to collect CPUE data or landings information. The utility and accuracy of both surveys has been questioned in recent years. NMFS also uses other programs to collect information on recreational fisheries for Atlantic HMS, including tournament registration and reporting and angler self-reporting systems. Mandatory call-in systems were implemented in 1997 for bluefin tuna, and in 2003 for Atlantic billfish and swordfish. NMFS is also working cooperatively with individual states to develop more effective monitoring of

Atlantic HMS recreational fisheries. North Carolina and Maryland both employ catch card and body tag systems that may serve as a model for future recreational data collection efforts.

Despite these data collection systems, NMFS seeks to further enhance its commercial and recreational data collection efforts. NMFS believes that better administration and coordination of reporting programs and requirements for dealers and fishermen of HMS species can ultimately streamline reporting requirements and procedures, thereby ensuring that information necessary for the management of HMS species is collected more efficiently and with less burden on fishermen. As such, NMFS would like to explore methods to improve the accuracy of data, either through rules or through administrative methods. However, stakeholders must also realize that quality data is dependent on their cooperation and efforts, including submission of accurate commercial and recreational landings on a timely basis. Some of the preferred measures in this FMP will begin to facilitate this improvement of data collected from HMS fisheries (*e.g.*, shark identification dealer workshops and the ability in the future for BFT dealers to report electronically). Additional changes are possible in the future.

# CHAPTER 2 TABLE OF CONTENTS

## CHAPTER 2 LIST OF TABLES

## CHAPTER 2 LIST OF FIGURES

# 2.0 SUMMARY OF ALTERNATIVES

## 2.1 Bycatch Reduction

### 2.1.1 Workshops

#### *2.1.1.1 Protected Species Safe Handling, Release, and Identification Workshops for Pelagic Longline, Bottom Longline, and Gillnet Fishermen*

These workshops are intended to reduce the mortality of sea turtles, marine mammals, and other protected species captured incidentally in the HMS pelagic longline (PLL), bottom longline (BLL), and gillnet fisheries. These workshops would disseminate information and demonstrate techniques specific to sea turtle safe handling and release protocols as per the current NMFS standards. Through these workshops, participants would be trained to safely disentangle, resuscitate, and release captured sea turtles, smalltooth sawfish, other protected species and non-target species, would teach participants how to properly identify protected species, and would provide information on key morphological characteristics, distribution, and basic life history to improve positive identification of protected species. Due to the nature of the workshop subject matter, hands-on training and interaction with the workshop leader is vital for initial skill development and certification. During these workshops, participants would be given a comprehensive hands-on examination, which, upon successful completion, would result in a multi-year certification. After the initial series of workshops, the Agency would continue to provide certification opportunities for permitted HMS fishery participants. Certification would be renewed on a specified timetable (*i.e*., 2, 3, or 5-year timetable) to ensure that the latest techniques to disentangle, release, and identify protected species are used. Additional certification requirements may be warranted in the future based upon reinitiation of consultation with the NMFS Office of Protected Resources or the receipt of significant new information related to handling and release protocols. While the workshop alternatives may be mandatory for certain individuals, to the extent practicable, the workshops would be open to interested individuals who wish to receive the workshop certification on a voluntary basis.

Alternative A1 Voluntary protected species safe handling, release, and identification workshops for longline fishermen (No Action)

Under alternative A1, the No Action alternative, NMFS would continue to provide voluntary safe handling and release workshops for PLL and BLL fishermen and continue to distribute wheelhouse placards, protocols, and educational videos, as well as disseminate additional information through the activities of the NMFS PLL Point of Contact (POC). No mandatory requirements would be implemented under this alternative.

Alternative A2 *Mandatory protected species safe handling, release, and identification workshops and certification for all HMS pelagic or bottom longline vessel owners – Preferred Alternative*

Alternative A2 would require mandatory workshops and certification for all vessel owners that have pelagic or bottom longline gear on their vessel and that have been issued or are required to be issued any of the HMS limited access permits (LAPs) to participate in HMS longline fisheries. Only HMS LAP owners with PLL or BLL gear on board their vessel are required to attend the workshop and receive a workshop certificate. These workshops would provide information and ensure proficiency with the safe handling, disentanglement, resuscitation, and release techniques for sea turtles, smalltooth sawfish, and other protected species. Additionally, the workshops would teach participants how to properly identify protected species, and provide information on key morphological characteristics, distribution, and basic life history to improve positive identification of protected species.

To receive their workshop certification, HMS LAP owners that fish with PLL or BLL gear would attend a workshop and demonstrate their understanding of the safe handling, disentanglement, resuscitation, release, and identification techniques. It is a refutable presumption that vessel owners and/or operators fish with longline gear if longline is on board the vessel; logbook reports indicate that longline gear was used on at least one trip in the preceding year; or in the case of a permit transfer to new owners that occurred less than a year ago, logbook reports indicate that longline gear was used on at least one trip since the permit transfer. HMS LAP(s) owners with PLL or BLL on board the vessel would be required to obtain their initial workshop certification prior to renewing their shark and swordfish limited access permit(s) in 2007. If the vessel owner holds multiple HMS LAPs, the owner would need to be certified prior to the earliest expiring shark or swordfish LAP in 2007.

For permit holders required to attend the workshop and receive a certificate, the permit holder must show a copy of their HMS permit, as well as proof of identification. If a permit holder is a corporation, partnership, association, or any other entity, the individual attending on behalf of the permit holder must show proof that he or she is the permit holder's agent and a copy of the HMS permit. The workshop certification would not be transferable to any other person and would state the name of the permit holder on the certificate. If acquiring an HMS LAP from a previous permit holder, the new owner would need to obtain a workshop certification prior to transferring the permit into the new owner's name. A copy of the owner's workshop certificate must be kept on board the vessel at all times.

The schedule for the protected species workshops would be available in advance to allow permit holders to select the workshop closest to them and most convenient to their schedule. If a permit holder is unable to attend a scheduled workshop, NMFS would consider granting one-on-one workshop training at the expense of the permit holder.

All owners that attended and successfully completed the industry-sponsored certification workshops, as documented by workshop facilitators, held on April 8, 2005, in Orlando, Florida, and on June 27, 2005, in New Orleans, Louisiana, would automatically receive valid protected species workshop certificates.

Alternative A3 *Mandatory protected species safe handling, release, and identification workshops and certification for vessel operators actively participating in HMS pelagic and bottom longline fisheries – Preferred Alternative*

Alternative A3 would require mandatory workshops and certification for vessel operators who intend to participate in HMS longline fisheries. Alternative A3 would ensure that at least one person on board and directly involved with a vessel's fishing activities is certified in the release and disentanglement protocols and identification of protected species.

The initial operator certification would be linked to the renewal of the vessel's HMS shark and swordfish LAP(s) in 2007; therefore, an operator would need to attend a workshop and receive the certification prior to the owner renewing any of the vessel's HMS shark and swordfish LAP(s) in 2007. If the vessel owner holds multiple HMS LAPs, the operator would need to be certified prior to the earliest expiration date on the either the shark or swordfish limited access permit in 2007. After the initial certification, the operator's certification is no longer linked to the renewal of a vessel's HMS LAPs and would need to be renewed prior to the expiration date on the operator's workshop certificate. The workshop certification would not be transferable to any other person and would have the operator's name on the certificate.

If the vessel's HMS LAP(s) has not yet expired in 2007, the operator has until the expiration of the vessel's HMS LAP(s) to continue operating the vessel without a workshop certification. If the vessel's shark or swordfish LAP has already been renewed in 2007, the operator would need to be certified and have a workshop certificate on board the vessel. After renewing the vessel's shark or swordfish LAP in 2007, operating a vessel with longline gear without a certified operator and a copy of the certificate on board would be illegal.

Operators are encouraged to transfer the knowledge and skills obtained from successfully completing the workshops to the crew members, potentially increasing the proper handling and release protocols, and identification of protected species. While crew members are not required to attend the workshops, to the extent practicable, the workshops would be open to anyone who wishes to attend and receive certification.

The schedule for the protected species workshops would be available in advance to allow operators to select the workshop closest to them and most convenient to their schedule. If an operator is unable to attend a scheduled workshop, NMFS would consider granting one-on-one workshop training at the expense of the individual.

All operators that attended and successfully completed the industry certification workshops, as documented by workshop facilitators, held on April 8, 2005, in Orlando, Florida, and on June 27, 2005, in New Orleans, Louisiana, would automatically receive valid protected species workshop certificates.

Alternative A4 Mandatory protected species safe handling, release, and identification workshops and certification for all HMS longline vessel owners, operators, and crew

Alternative A4 would require mandatory protected species safe handling, release, and identification workshops and certification for all HMS longline vessel owners, operators, and crewmembers. Attendance and successful completion of a workshop would be linked to an owner's ability to renew an HMS permit. This alternative would allow the Agency to certify at least two individuals per vessel that would be associated with fishing activities on board the vessel. Unless the owners, operators, and crew attend and successfully complete the workshop, an HMS permit would not be issued to the vessel. At least one trained person must be onboard during fishing activities to provide proof of certification.

Alternative A5 *Mandatory protected species safe handling, release, and identification workshops and certification for shark gillnet vessel owners and operators – Preferred Alternative*

Alternative A5 would require mandatory protected species safe handling, release, and identification workshops and certification for all shark gillnet vessel owners that have been issued a Federal directed or indirect shark permit, as well as gillnet vessel operators. It is a rebuttable presumption that vessel owners and/or operators fish with gillnet gear if a gillnet is on board the vessel; logbook reports indicate that gillnet gear was used on at least one trip in the preceding year; or in the case of a permit transfer to new owners that occurred less than a year ago, logbook reports indicate that gillnet gear was used on at least one trip since the permit transfer. These workshops would provide information and ensure proficiency with the safe handling and release techniques for sea turtles, smalltooth sawfish, and other protected species. Additionally, the workshops would teach participants the proper identification of protected species, and would provide information on key morphological characteristics, distribution, and basic life history to improve positive identification of protected species.

Attendance and successful completion of a workshop would be linked to an owner's ability to renew an HMS fishing permit. A copy of the owner's workshop certificate would need to be submitted with the HMS LAP renewal request as proof of successful completion of the protected species workshops. Shark gillnet vessel owners would be required to attend a workshop and receive a certification prior to the expiration date on their shark LAP in 2007 to renew their permit. For their initial certification only, an operator would also need to attend a workshop and receive the certification prior to renewing the vessel's shark permit in 2007. After the initial certification, the operator's certification is no longer linked to the renewal of the vessel's permit and would need to be renewed prior to the expiration date on the operator's workshop certificate.

For shark permit holders required to attend the workshop and receive a certificate, the permit holder must show a copy of their shark LAP, as well as proof of identification. If a permit holder is a corporation, partnership, association, or any other entity, the individual attending on behalf of the permit holder must show proof that he or she is the permit holder's agent and a copy of the shark LAP. The workshop certification would not be transferable to any other person and would state the name of the permit holder on the certificate. If acquiring a shark LAP from a previous permit holder, the new owner would need to obtain a workshop certification prior to transferring the permit into the new owner's name.

If the vessel's directed or indirect shark permit has not yet expired in 2007, the owner and operator would have until the expiration of the permit to continue operating the vessel without a workshop certification. If the vessel's shark permit has already been renewed in 2007, the owner and operator would need to have a workshop certificate on board the vessel. Both the owner's and operator's workshop certificate would need to be kept on board the vessel to verify successful completion of the safe release, disentanglement, and identification workshop. This alternative would ensure that at least one person on the vessel, who is directly involved with a vessel's fishing activities, is certified in the safe handling and release protocols and identification of protected species.

The schedule for the protected species workshops would be available in advance to allow owners and operators to select the workshop closest to them and most convenient to their schedule. If an owner or operator is unable to attend a scheduled workshop, NMFS would consider granting one-on-one workshop training at the expense of the individual.

Alternative A6 *Protected species safe handling, release, and identification certification renewal every 3-years – Preferred Alternative*

Alternative A6 would require the renewal of the mandatory protected species safe handling, release, and identification workshop certifications every three years. Permit holders employing longline or gillnet gear, including those grandfathered into these requirements, would be required to attain recertification every three years before renewing their shark and swordfish LAPs or tuna longline permits. Proof of the owner's valid workshop certification would need to be submitted to renew an HMS permit. Operators, including those grandfathered into these requirements, would need to renew the workshop certification every three years prior to the expiration date on the workshop certification.

Once the first round of certifications are complete, NMFS would explore alternative means for renewing permits, including online or mail-in options. The Agency also hopes to develop an online program that would serve as a medium for providing up-to-date information regarding protected species handling techniques. In addition to considering alternative timetables for certification renewal (*i.e.*, every two or five years), NMFS considered combining this alternative with each of the mandatory workshop alternatives listed above in the DEIS.

#### *2.1.1.2 HMS Identification Workshops*

Proper identification of HMS, as well as threatened and endangered species that fishermen may interact with while pursuing HMS, is paramount to the efficacy of HMS regulations and management. Permitted fish dealers and fishermen are responsible for accurately identifying HMS on the dealer reports and logbooks submitted to NMFS. These reports form the basis of quota monitoring activities and stock assessments. Misidentification of HMS can negatively impact stock assessments, calculation of season lengths, and influence the criteria used to designate certain species as prohibited. Identification workshops would help shark dealers and/or their proxies improve their shark identification skills. These workshops would be most effective if held at venues where live and/or freshly dead specimens could be displayed. After the initial series of workshops, the Agency would continue to provide certification opportunities for permitted HMS fishery participants. The preferred alternative would require the renewal of HMS identification certifications on a three-year timetable to ensure that the latest techniques to properly identify commonly caught HMS are used. While the workshop alternatives may be mandatory for certain individuals, to the extent practicable, the workshops would be open to interested individuals who wish to receive the workshop certification on a voluntary basis (*e.g.*, fishermen, dealers, law enforcement officials, and port agents).

Alternative A7 No HMS identification workshops (No Action)

Under alternative A7, the No Action alternative, NMFS would continue to support dissemination of information through the Guide to Sharks, Tunas, & Billfishes of U.S. Atlantic & Gulf of Mexico, to enhance fishery participant's ability to accurately identify species commonly caught in HMS fisheries. No mandatory requirements would be implemented under this alternative.

Alternative A8 Voluntary HMS identification workshops for dealers, all commercial vessel owners and operators, and recreational fishermen

Under alternative A8, NMFS would hold voluntary HMS identification workshops for dealers, commercial vessel owners and operators, and recreational fishermen. These workshops would be held in addition to the items listed under the No Action alternative (A7) above. No mandatory requirements would be implemented under this alternative.

Alternative A9 *Mandatory shark identification workshops for all shark dealers – Preferred Alternative*

Alternative A9 would require mandatory shark identification workshops for all Federally permitted shark dealers. Attendance and successful completion of a workshop would be linked to a dealer's ability to renew their Federal shark dealer permit. All Federally permitted shark dealers would have to successfully complete the shark identification workshop by December 31, 2007. The permit holder would be required to submit proof of a workshop certification when renewing the shark dealer permit. Also, proof of a workshop certification would need to be available at the dealer's place of business for inspection. Without a certificate indicating successful completion of the workshop, Federal shark dealer permit would not be issued. Shark identification workshops would be mandatory for Federally permitted shark dealers, but, to the extent possible, these workshops would be open to other interested individuals (*e.g.,* individuals participating in the shark fishery, port agents, law enforcement officers, state shark dealers, and recreational fishermen) on a voluntary basis.

If the permitted dealer is unable to attend or is not directly involved in species identification, then a proxy could be sent to meet mandatory attendance and certification requirements. The proxy must be a person who is currently employed by a place of business covered by the dealer's permit; is a primary participant in the identification, weighing, or first receipt of fish as they are offloaded from a vessel; and is involved in filling out dealer reports. If a dealer opts to send a proxy, the dealer would be required to designate a proxy for each place of business covered by the dealer's permit. Only one certificate will be issued to each proxy. Under this alternative, Federally permitted shark dealers would be held accountable for ensuring that the appropriate individuals receive the proper training in shark identification. NMFS encourages shark dealers to send as many proxies as necessary to train the individuals responsible for shark species identification within the dealer's business. Multiple trained and certified proxies per shark dealer would ensure that the dealer has at least one person on staff with the workshop certification and skills to properly identify sharks.

For shark dealers required to attend the Atlantic shark identification workshop certificate, the dealer must show a copy of their HMS permit, as well as proof of identification. If a permit holder is a corporation, partnership, association, or any other entity, the individual attending on behalf of the permit holder must show proof that he or she is the permit holder's agent, as well as a copy of the HMS permit. For proxies attending on behalf of a shark dealer permit holder, the proxy must have documentation from the permit holder acknowledging that the proxy is attending the workshop on behalf of the Atlantic shark dealer permit holder and must show a copy of the Atlantic shark dealer permit. A dealer or the designated proxy would be required to bring a copy of the dealer permit to the workshop to guarantee that the dealer receives credit for the certification, as the workshop certification would be linked to the dealer's permit number.

The schedule for shark identification workshops would be available in advance to allow dealers and proxies to select the workshop closest to them and most convenient to their schedule. If a dealer and/or proxy are unable to attend a scheduled workshop, NMFS would consider granting one-on-one workshop training at the expense of the shark dealer permit holder. One-on-one training sessions could also accommodate the replacement of a proxy whose employment was terminated on short notice.

Alternative A10 Mandatory HMS identification workshops for all swordfish, shark, and or/tuna dealers

Alternative A10 would require mandatory HMS identification workshops for all swordfish, shark, and/or tuna dealers. Attendance and successful completion of a workshop would be linked to a dealer's ability to renew a Federal dealer permit. If the permitted dealer was unable to attend or is not directly involved in dealer activities, then a proxy could be sent to meet mandatory attendance requirements. If a dealer opts to send a proxy, then the dealer must designate a proxy from each place of business covered by the dealer's permit. A proxy must be a person who is employed by a place of business, covered by a dealer's permit, a primary participant in identification, weighing, or first receipt of fish as they are offloaded from a vessel, and involved in filling out dealer reports. Without a certificate indicating successful completion of the workshop, no permit would be issued.

Alternative A11 Mandatory HMS identification workshops for all commercial longline vessel owners

Alternative A11 would require mandatory HMS identification workshops for all vessel owners issued HMS LAPs and using longline gear. Attendance and successful completion of a workshop would be linked to an owner's ability to renew a HMS fishing permit. Without a certificate indicating successful completion of the workshop, a HMS permit or permit renewal would not be issued to a vessel that has logbook reports indicating longline use.

Alternative A12 Mandatory HMS identification workshops for all commercial longline vessel operators

Alternative A12 would require mandatory HMS identification workshops for all commercial longline vessel operators. The initial operator certification would be linked to the vessel's HMS permit renewal.  An operator would need to attend a workshop and receive the certification prior to the renewal of the vessel's HMS permit in 2007.

Alternative A13 Mandatory HMS identification workshops for all commercial vessel owners (longline, CHB, General category, and handgear/harpoon)

Alternative A13 would require mandatory HMS identification workshops for all commercial vessel owners with an HMS permit.  Attendance and successful completion of a workshop would be linked to an owner's ability to renew a HMS fishing permit.  Without a certificate indicating successful completion of the workshop, a HMS permit would not be issued to the vessel.

Alternative A14 Mandatory HMS identification workshops for all commercial vessel operators (longline, CHB, General category, and handgear/harpoon)

Alternative A14 would require mandatory HMS identification workshops for all commercial vessel operators.  The initial operator certification would be linked to the vessel's HMS permit renewal.  An operator would need to attend a workshop and receive the certification prior to renewing the vessel's certification in 2007.

Alternative A15 Mandatory HMS identification workshops for all HMS Angling category permit holders

Alternative A15 would require mandatory HMS identification workshops for all HMS Angling permit holders, the largest category of HMS permit holders.  Attendance and successful completion of a workshop would be linked to an owner's ability to renew a HMS Angling category fishing permit.  Without a certificate indicating successful completion of the workshop, no HMS Angling category permit would be issued.

Alternative A16 *HMS identification certification renewal every 3-years – Preferred Alternative*

Alternative A16 would require renewal of mandatory HMS identification workshop certifications every three years.  In conjunction with alternative A9, Federally permitted shark dealers would be required to recertify every three years before renewing their Federal dealer permits.  Proof of a valid workshop certification would need to be submitted to renew their Federal dealer permit.  If the dealer opts to send a proxy or proxies, a copy of a workshop certificate for every business covered by the dealer's permit must be included with the renewal application.

Due to the nature of workshop subject matter, hands-on training and interaction with the workshop leader is vital for initial skill development and certification.  Once the first round of certifications are complete, NMFS would explore alternative means for renewing permits, including online or mail-in options.  The Agency also hopes to develop an online program that would serve as a medium for providing up-to-date information regarding HMS identification.  In addition to considering alternative timetables for certification renewal (*i.e.*, every two or five years), NMFS considered combining this alternative with each of the mandatory workshop alternatives listed above.

*<u>Other workshop alternatives considered but not further analyzed at this time</u>*

Alternative A17 Compliance With, and Understanding of, HMS Regulations

Constituents have expressed concern over the complexity of HMS regulations. Workshops providing a thorough explanation of HMS regulations and management history would likely be beneficial and may result in improved public relations on behalf of the Agency, improved compliance with regulations, and understanding of the HMS regulatory process.

During the scoping process for the Issues and Options Paper and Pre-draft for this document, NMFS received comments noting that workshops held by the agency should be prioritized. Furthermore, comments received were supportive of continuing to disseminate information pertaining to HMS regulations (*e.g.*, annual HMS Compliance Guide) rather than spending Federal dollars to hold workshops on regulations at this time. Advisory Panel members were supportive of focusing on mandatory requirements (*i.e.*, workshops required under Biological Opinions and other mandates) first and then following up with additional hard copy outreach materials to meet regulatory informational needs. Since NMFS already disseminates this type of information on a regular basis and given that this information can be distributed to participants attending either the handling/release and/or identification workshops, this alternative is not being further analyzed at this time. NMFS may reconsider this alternative in the future, if appropriate.

### 2.1.2 Time/Area Closures

The first time/area closure for HMS was implemented in the 1999 FMP with the Northeastern U.S. closure off New Jersey in June 1999 to reduce bluefin tuna (BFT) discards. Since then, additional closures have been implemented in the DeSoto Canyon (2000), Florida East Coast (2001), Charleston Bump, Northeast Distant (2001), and the Mid-Atlantic shark closed area (2005) (Figure 2.1). The goals of all of the HMS time/area closures are to: (1) maximize the reduction in bycatch; (2) minimize the reduction in the target catch; and (3) consider impacts on non-target HMS (*i.e.*, BFT) to minimize or reduce non-target catch levels.

These time-area closures have proven to be effective at reducing bycatch. However, despite these closures, several non-target HMS such as blue and white marlin, sailfish, and BFT are overfished with overfishing occurring, and protected species, such as leatherback and loggerhead sea turtles, continue to interact with HMS gears. As a result, NMFS considered additional closures to further reduce these interactions. However, possibly because of these closures, landings, such as swordfish, and pelagic longline (PLL) effort have decreased over the years. Therefore, NMFS considered modifications to existing closures as a means to increase the catch of Atlantic swordfish.

NMFS considered the following alternatives, ranging from the No Action alternative of maintaining existing closures to a complete prohibition of certain HMS gear types. Some of the alternatives are grouped according to the specific objectives of the closed areas. Thus, alternatives B2(a) through B2(k), B4, and B6 consider new closure areas for HMS to primarily address white marlin, BFT, sea turtle, and smalltooth sawfish bycatch, whereas alternatives B3(a) through B3(d) consider alternatives for modifying existing closures. Alternative B5 considers criteria for implementing new closures and/or modifying existing closure whereas alternative B7 considers prohibiting the use of PLL gear in HMS fisheries. For details on the methods used to consider alternatives and select alternatives for further analysis see Section 4.1.2 and Appendix A.

Alternative B1 Maintain existing time/area closures; no new time/area closures (No Action)

This alternative would maintain the existing time/area closures. It would not implement any new time/area closures nor modify any existing closures. The current time/area closures are shown in Figure 2.1.

Alternative B2(a) Prohibit the use of PLL gear in HMS fisheries in the central portion of the Gulf of Mexico from May through November (7 months), annually

This alternative would prohibit the use of PLL gear by all U.S. flagged-vessels permitted to fish for HMS in the central portion of the Gulf of Mexico where blue and white marlin, sailfish, spearfish, BFT, and leatherback and loggerhead sea turtles have been observed and reported caught year-round, but with highest concentrations from May through November. This closure would encompass approximately 11,991 square nautical miles ($nm^2$) and would be defined as the area within the following coordinates, beginning with the northeastern corner and proceeding clockwise: 27º 10’ N. latitude (Lat.), 90º 29’ W. longitude (Long.); 25º 47’ N. Lat., 90º 29’ W. Long.; 25º 47’ N. Lat., 93º 10’ W. Long.; 27º 10’ N. Lat., 93º 10’ W. Long. (Figure 2.2).

Alternative B2(b) Prohibit the use of PLL gear in HMS fisheries in an area of the Northeast during the month of June (1 month), each year

This alternative would prohibit the use of PLL gear by all U.S. flagged-vessels permitted to fish for HMS in a portion of the Northeast where large numbers of BFT is discarded during the month of June each year. This closure would encompass approximately 2,251 $nm^2$ and would be defined as the area within the following coordinates, beginning with the northern-most corner and proceeding clockwise: 41º 15’ N. Lat., 66º 41’ W. Long.; 40º 48’ N. Lat., 66º 14’ W. Long.; 39º 50’ N. Lat., 67º 22’ W. Long.; 40º 17’ N. Lat., 67º 49’ W. Long. (Figure 2.2).

Alternative B2(c) Prohibit the use of PLL gear in HMS fisheries in the central Gulf of Mexico from April through June (3 months), annually

This alternative would prohibit the use of PLL gear by all U.S. flagged-vessels permitted to fish for HMS in a central portion of the Gulf of Mexico from April through June (three months), annually. This area was mainly considered to protect BFT that spawn in the Gulf of Mexico. NMFS took into account information received in a petition for rulemaking to consider a closure to reduce BFT discards in a reported spawning area in the Gulf of Mexico (Blue Ocean Institute *et al*., 2005; Block *et al*., 2005). This closure would encompass approximately 101,670 $nm^2$ and would be defined as the area within the following coordinates, beginning with the northwest corner and proceeding clockwise: 28° 00’ N. Lat., 96° 00’ W. Long.; 28° 00’ N. Lat., 92° 00’ W. Long.; 29° 00’ N. Lat., 92° 00’ W. Long.; 29° 00’ N. Lat., 86° 00’ W. Long.; 28° 00’

N. Lat., 86° 00’ W. Long.; 28° 00’ N. Lat., 85° 00’ W. Long.; 27° 00’N. Lat., 85° 00’ W. Long.; 27° 00’ N. Lat., 86° 00’ W. Long.; 26° 00’ N. Lat., 86° 00’ W. Long.; 26° 02’ N. Lat., 86° 17’ W. Long.; following the EEZ until 26° 00’ N. Lat., 96° 00’ W. Long. (Figure 2.2).

Alternative B2(d) Prohibit the use of PLL gear in HMS fisheries in the Gulf of Mexico west of 86° W. Longitude year-round

This alternative would prohibit the use of PLL gear by all U.S. flagged-vessels permitted to fish for HMS in the Gulf of Mexico west of 86° W. Longitude year-round. This alternative would close an area where approximately 50 percent of all effort (Atlantic, Gulf of Mexico, and Caribbean) and 90 percent of all effort in the Gulf of Mexico has been reported in recent years (2001 – 2003). Closing this area would help reduce interactions for a number of different species. This closure would encompass approximately 162,181 $nm^2$ west of 86° 00’ W. Long., 25° 00’ N. Lat. between the State Territorial Sea and the EEZ boundary (Figure 2.2).

Alternative B2(e) Prohibit the use of PLL gear in HMS fisheries in an area of the Northeast to reduce sea turtle interactions year-round

This alternative would prohibit the use of PLL gear by all U.S. flagged-vessels permitted to fish for HMS in an area of the Northeast year-round. This area was primarily considered to reduce loggerhead sea turtle interactions, which occur with greater frequency in this area than in nearly all other areas. This closure would encompass approximately 46,956 $nm^2$ and would be defined as the area within the following coordinates, beginning with the western-most corner and proceeding clockwise: 39° 59’ N. Lat., 71° 50’ W. Long.; 41° 18’ N. Lat., 66° 26’ W. Long.; 40° 27’ N. Lat., 66° 42’ W. Long.; 37° 53’ N. Lat., 70° 28’ W. Long. (Figure 2.2).

Alternative B3(a) Modify the existing Charleston Bump time/area closure to allow the use of PLL gear in all areas seaward of the axis of the Gulf Stream

This alternative would modify the existing Charleston Bump time/area closure by moving the eastern boundary at 76º W. Long. to the west following the axis of the Gulf Stream from the existing northeast corner of the closure southwest to 31º N. Lat., 79º 16’ Long. This alternative would reopen areas seaward of the axis of the Gulf Stream previously closed to PLL gear from February 1 through April 30. In particular, this alternative would provide additional opportunity to harvest North Atlantic swordfish, for which the quota has not been harvested in recent years (Figure 2.3).

Alternative B3(b) Modify the existing Northeastern U.S. time/area closure to allow the use of PLL gear in areas west of 72º 47’ W. Long. during the month of June each year

This alternative would modify the existing Northeastern U.S. time/area closure boundary to allow PLL gear in areas west of 72º 47’ W. Long. during the month of June each year. This alternative would reopen an area in which there were historically low numbers of BFT discards. This alternative would provide additional opportunity to harvest North Atlantic swordfish and other targeted HMS such as yellowfin tuna (Figure 2.3).

Alternative B4 *Implement complementary HMS management measures in Madison-Swanson and Steamboat Lumps Marine Reserves year-round – Preferred alternative*

This alternative would implement HMS management measures in the Madison-Swanson and Steamboat Lumps Marine Reserves to complement measures for these reserves recommended by the Gulf of Mexico Fishery Management Council (GMFMC). These reserves would prohibit all HMS fishing for all gear types year-round except for surface trolling only from May through October. The HMS management measures would expire on June 16, 2010, consistent with GMFMC recommendations. Both of these reserves are located shoreward of the Desoto Canyon Closed Area. The Madison-Swanson Marine Reserve is 115 $nm^2$ in size, rectangular-shaped, and is positioned southwest of Apalachicola, FL (29° 17' N. Lat., 85° 50' W. Long. to 29° 17' N. Lat., 85° 38' W. Long. to 29° 06' N. Lat., 85° 38' W. Long. to 29° 06' N. Lat., 85° 50' W. Long. to 29° 17' N. Lat., 85° 50' W. Long.). The Steamboat Lumps marine reserve is 104 $nm^2$ in size, rectangular-shaped, and is positioned due west of Clearwater, FL (28° 14' N. Lat., 84° 48' W. Long. to 28° 14' N. Lat., 84° 37' W. Long. to 28° 03' N. Lat., 84° 37' W. Long. to 28° 03' N. Lat., 84° 48' W. Long. to 28° 14' N. Lat., 84° 48' W. Long. (Figure 2.4)

Alternative B5 *Establish criteria to consider when implementing new time/area closures or making modifications to existing time/area closures – Preferred alternative*

This alternative would establish criteria for regulatory framework adjustments for implementing new time/area closures or making modifications to existing time/area closures. These criteria would provide greater transparency in the decision making process and allow fishermen more ability to plan for future changes. Consistent with the FMP, the Magnuson-Stevens Act and other applicable law criteria that were identified for consideration, included the following: any ESA-related issues, concerns, or requirements, including applicable Biological Opinions; bycatch rates of protected species, prohibited HMS, or non-target species both within the specified or potential closure area(s) and throughout the fishery; bycatch rates and post-release mortality rates of bycatch species associated with different gear types; new or updated landings, bycatch, and fishing effort data; evidence or research indicating that changes to fishing gear and/or fishing practices can significantly reduce bycatch; social and economic impacts; and the practicability of implementing new or modified closures compared to other bycatch reduction options. If the species is an ICCAT-managed species, NMFS would need to determine the overall effect of the United States' catch on that species before implementing time/area closures.

NMFS also considered modifying the current closed areas using these same criteria and GIS mapping techniques to better pinpoint areas of low bycatch within closed areas (based on catch data from pelagic logbooks collected before an area was closed) (see Section 4.1.2). The current time/area closures were not intended to be permanent. Rather, NMFS intended to modify existing closures, as appropriate, to allow utilization of a given fishery consistent with the FMP once the objective of the time/area closure had been met. Additionally, because fisheries, fishing gear, fishing practices, and stock status change over time, periodically NMFS must examine the continued need for existing time/area closures. One method of doing this would be for NMFS to conduct, fund, or support research, such as testing methods for reducing bycatch of protected, prohibited, and non-target species. Such research would need to be part of a scientifically justified research plan, identifying the rationale, objectives, methodology, and experimental design of the research. The scope and magnitude in terms of ecological and socio-economic impact would be considered as part of any research proposal. Research in both open and closed areas may be warranted to collect data on the spatial and temporal relationship between target and bycatch species and to provide data for use in considering the criteria listed above. Such research could be cooperative in nature to include different stakeholders in the process.

Alternative B6 Prohibit the use of bottom longline gear in an area southwest of Key West to protect endangered smalltooth sawfish year-round

This alternative would prohibit the use of bottom longline gear by all U.S. flagged-vessels permitted to fish for HMS in an area southwest of Key West where smalltooth sawfish have been observed and caught year-round. This area would encompass approximately 49 $nm^2$ and would be defined as the area on the southwest tip of Key West, bordering the state waters with the following coordinates, beginning with the northwest corner and proceeding clockwise: 24° 29' N. Lat., 82° 06' W. Long.; 24° 29' N. Lat., 82° 02' W. Long.; 24° 24' N. Lat., 81° 58'W. Long.; 24° 23' N. Lat., 81° 58' W. Long., 24° 23'N. Lat. 82° 06' W. Long. (Figure 2.5)

Alternative B7 Prohibit the use of PLL gear in HMS fisheries in all areas

This alternative would prohibit the use of PLL gear in HMS fisheries in all areas to enhance the rebuilding of overfished stocks and reduce bycatch and bycatch mortality.

***<u>Other time/area closure alternatives considered but not further analyzed at this time</u>***

Below are a number of closure alternatives that were considered and eliminated from further consideration before being fully analyzed (Figure 2.6). The descriptions below include the reasons why the alternatives were not further analyzed at this time. More detail about these alternatives can be found in Appendix A. These alternatives may be considered in the future as needed.

Alternative B2(f) Prohibit the use of PLL gear in HMS fisheries in the central portion of the Gulf of Mexico in an area similar to, but larger than the area considered in alternative B2(a), from May through November (7 months), annually

Alternative B2(g) Prohibit the use of PLL gear in an area off the Northeast Atlantic coast from the 200 meter contour to the 2000 meter contour between the eastern tip of Georges Bank (66º 10' W. Long.) to Cape Hatteras (35º N. Lat.) from June through October, annually

Alternative B2(h) Prohibit the use of PLL gear in an area off the Southeast Atlantic coast from the 200 meter contour to the 2000 meter contour between Cape Hatteras (35º N. Lat.) and Cape Canaveral (29º N. Lat.) from March through November, annually

Alternative B2(i) Prohibit the use of PLL gear in an area adjacent to the eastern boundary of the existing Florida East Coast closure from 29º N. to 28º 25' N. and seaward to the 2000 meter contour year-round

Alternative B2(j) Prohibit the use of PLL gear in HMS fisheries in the Gulf of Mexico from the 200 meter contour to the 2000 meter contour from the Straits of Florida (82º W. Long.) to the border between the United States and Mexico (26º N. Lat.) year-round

Alternative B2(k) Prohibit the use of PLL gear in HMS fisheries in the Caribbean from the 200 meter contour to the 2000 meter contour on the west coast of Puerto Rico during certain times of each year

Alternative B3(c) Modify the Florida East Coast time/area closure to allow the use of PLL gear in the northeast and southwest corners of the existing closure

Alternative B3(d) Modify the existing DeSoto Canyon time/area closure to allow the use of PLL gear in all areas seaward of the 2000 meter contour

Alternative B2(f) would prohibit the use of PLL gear by all U.S. flagged-vessels permitted to fish for HMS in a portion of the central Gulf of Mexico from May to November, annually. This is similar to, but larger than the area described in alternative B2(a), where blue and white marlin, sailfish, spearfish, BFT, and sea turtles have been observed and caught year-round, but with highest concentrations occurring from May through November. Without redistribution of fishing effort, this closure would result in a relatively large decrease in the number of discards for blue and white marlin (Tables A.1 and A.2 in Appendix A). This closure would encompass approximately 17,219 $nm^2$ and would be defined as the area within the following coordinates, beginning with the northeastern corner and proceeding clockwise: 27º 10' N. Lat., 89º 11' W. Long.; 25º 44' N. Lat., 89º 11' W. Long.; and following the EEZ boundary to 26º 10' N. Lat., 93º 10' W. Long., 27º 10' N. Lat., 93º 10' W. Long. (Figure 2.6)

When redistribution of fishing effort was considered, a seven-month closure for alternative B2(f) was predicted to result in an increase in the number of swordfish, BFT, and bigeye tuna discards (2,081, 219, and 150 discards over three years for the seven-month closure, respectively; Table A.5 in Appendix A). NMFS compared possible reductions and increases of discards and targeted catch with the redistribution of effort for B2(f) with results from other closures. For instance, B2(f) is larger in size than B2(a). Thus, NMFS would expect a greater ecological benefit in terms of bycatch reduction from the larger B2(f) closure rather than the smaller B2(a) closure. However, the model predicted comparable results in terms of bycatch reduction between B2(a) and B2(f) (Tables A.1 and A.2 in Appendix A). In addition, B2(a) would not have resulted in as many BFT discards or potentially had as large of a negative economic impact in terms of a reduction in retained catch as B2(f). B2(f) is also smaller than B2(d). However, NMFS choose to analyze the larger closure to better assess the ecological, social and economic impacts of a large B2(d) closure in the Gulf of Mexico. Therefore, by further analyzing B2(a) and B2(d), NMFS was able to analyze a range in terms of potential ecological, social, and economic impacts with regard to the size of a closure in this area of the Gulf of Mexico.

Alternatives B2(g) – (k) were considered due to their overlap with existing EFH areas for white marlin and information indicating bycatch of non-target HMS species as well as sea turtles. NMFS specifically took into account five suggested white marlin time/area closures in the U.S. EEZ described on page 10 in a February 14, 2002, letter from the Biodiversity Legal Foundation, re: Atlantic White Marlin Critical Habitat Designation. NMFS agreed to take these five areas into account, among other things, as part of a settlement agreement in Center for Biological Diversity v. NMFS, Civ. Action No. 04-0063 (D.D.C.). Data from the Highly Migratory Species (HMS) logbook (*i.e.*, the logbook the PLL fleet uses) and pelagic observer program (POP) were analyzed for these specific areas to determine the percent reduction in discards with and without redistribution of fishing effort (described in detail in Chapter 4 and Appendix A). The analyses indicated that, while there may be some benefit from closures without the redistribution of fishing effort, in nearly all cases, bycatch increased with the redistribution of fishing effort in one or more of these areas, or other areas had higher rates of bycatch and produced larger ecological benefits with fewer social and economic impacts in the redistribution of fishing effort analyses. Additionally, because these alternatives follow contour lines, they would be difficult to enforce and difficult for fishermen to know if they were fishing inside a closed area or not. Therefore, while NMFS presents some analyses here and in Appendix A, alternatives B2(g) – (k) were not further analyzed in Chapter 4.

Alternative B2(g) would prohibit the use of PLL gear by all U.S. flagged-vessels permitted to fish for HMS in portions of the Northeast in areas where white marlin are concentrated during certain times of the year and have been observed and reported caught from June through October (Figure 2.6). This time period also corresponds to higher catches of all other species considered (blue marlin, sailfish, spearfish, leatherback and loggerhead sea turtles and BFT; Table A.10 in Appendix A). Without considering redistribution of fishing effort, closing B2(g) could result in a reduction in the number of discards for all species considered (Tables A.1 and A.2 in Appendix A). However, when redistribution of fishing effort was considered, there was a predicted increase in the number of discards for white marlin, blue marlin, sailfish, spearfish, leatherback and other sea turtles, with the largest increase in discards expected for blue marlin, sailfish, and spearfish (20.2, 23.2, and 14.5 percent, respectively; Table A.2 in Appendix A). Loggerhead sea turtles were the only species with an expected decrease in discards under the redistribution model. This closure followed contour lines from Maine to North Carolina. The temporal and spatial aspects of B2(g) are different than any other closures in this area. B2(b) and B2(e) are also located off the Northeast. A year-round closure for B2(e) could result in less of an increase in discards of blue marlin, sailfish, and spearfish with redistribution of effort (Table A.1 in Appendix A). In addition, B2(e) could result in a larger decrease in leatherback and loggerhead sea turtles, and BFT discards (Table A.1 in Appendix A). However, B2(e) was considered year-round whereas B2(g) was only considered for June through October. NMFS determined that a one month closure (June) for B2(b) may have a greater ecological benefit by decreasing the number of discards of white marlin, blue marlin, sailfish, and spearfish. In addition, it could reduce leatherback sea turtle discards as well as loggerhead sea turtles discards and have a comparable reduction in BFT discards as B2(g) (Table A.2 in

Appendix A). Given these results, alternatives B2(b) and B2(e) were further analyzed, while B2(g) was not.

Alternative B2(h) would prohibit the use of PLL gear by all U.S. flagged-vessels permitted to fish for HMS in portions of the Southeast where white marlin are concentrated during certain times of the year and have been observed and caught year-round (Figure 2.6). Without considering redistribution of fishing effort, the model predicted a small decrease in the percentage of discards, with the exception of sailfish (Tables A.2 in Appendix A). When redistribution of fishing effort was considered, the ecological impacts of B2(h) would likely be minor (the predicted decreases in the number of discards were small and typically less than eight percent; Table A.2 in Appendix A). There would be almost no decrease in the number of discards for blue marlin, a slight increase in the number of discards for white marlin, and a moderate increase in the number of discards of both leatherback and loggerhead sea turtles (Tables A.1 and A.2 in Appendix A). This closure did not spatially overlap any of the other closures further analyzed. However, given the minimal ecological benefits for some species and the negative ecological impact for white marlin and sea turtles, this alternative was not further analyzed.

Alternative B2(i) would prohibit the use of PLL gear by all U.S. flagged-vessels permitted to fish for HMS in portions of the east coast of Florida where white marlin are concentrated during certain times of the year and have been observed and caught year-round (Figure 2.6). As with B2(h), this closure did not spatially overlap with any of the other closures that were further analyzed. However, even without considering redistribution of fishing effort, the reduction in bycatch associated with B2(i) was small, with the highest expected reduction for blue marlin (316 fish for 3 years or 12.9 percent; Tables A.1 and A.2 in Appendix A). When redistribution of fishing effort was considered, the model predicted only slight decreases in discards of white and blue marlin, sailfish and loggerhead sea turtles, with all decreases less than ten percent (Table A.2 in Appendix A). However, there were predicted increases in spearfish, leatherback sea turtle, and BFT discards (Tables A.1 and A.2 in Appendix A). Thus, given the potential negative ecological impacts of this closure, this alternative was not further analyzed.

Alternative B2(j) would prohibit the use of PLL gear by all U.S. flagged-vessels permitted to fish for HMS in portions of the Gulf of Mexico where white marlin are concentrated during portions of the year and have been observed and reported caught year-round (Figure 2.6). Without considering redistribution of fishing effort, B2(j) could have decreased discards of all species considered, especially blue marlin, sailfish and spearfish (21.6, 43.1, 25.5 percent, respectively; Table A.2 in Appendix A). However, when redistribution of fishing effort was considered, the model predicted an increase in the number of discards, especially for loggerhead sea turtles (22.3 percent; Table A.2 in Appendix A). While there were predicted decreases in discards of sailfish and spearfish (Tables A.1 and A.2 in Appendix A), the net effect could be a negative ecological impact. This closure was a spatially large closure in the Gulf of Mexico that could also have a large economic impact, especially for a year-round closure. Given other closures in the Gulf of Mexico that were further analyzed (B2(a), B2(c), and B2(d)) varied in size and time period, this alternative was not further analyzed.

Alternative B2(k) would prohibit the use of PLL gear by all U.S. flagged-vessels permitted to fish for HMS in portions of the Caribbean where white marlin are concentrated and have been observed and caught during certain times of the year (Figure 2.6). Bycatch occurs primarily from December through April. As with B2(h) and B2(j), this closure did not spatially overlap with any of the other closures that were further analyzed. However, even without considering redistribution of fishing effort, the effort and reduction in bycatch associated with B2(k) was small, with the predicted reduction in the number of hooks and discards extremely low (less than one percent; Tables A.1 and A.2 in Appendix A). When redistribution of fishing effort was considered, there was only a slight decrease in the number of discards for white and blue marlin, and a slight increase in the number of discards for leatherback sea turtles and BFT discards (less than two percent; Table A.2 in Appendix A.2). Thus, the overall ecological impact due to this time/area closure would probably be relatively minor, resulting in no net decrease in discards for any of the species considered. Therefore, this alternative was not further analyzed.

In addition to proposing new closed areas, NMFS considered modifying current or existing time/area closures (alternatives B3(a) through B3(d)). In general, closed areas considered for modification (*i.e.*, partial re-opening) were chosen based on examining the PLL and POP data from 1997 through 1999. The data were analyzed in GIS, allowing NMFS to identify areas associated with minimal bycatch within current time/area closures for re-opening. Alternatives B3(a) and B3(b) were chosen for further analysis whereas alternatives B3(c) and B3(d) were initially examined but not further analyzed based on the reasons outlined below.

Alternative B3(c) would modify the Florida East Coast time/area closure by moving the eastern boundary at 27º N Lat., 30’ W Long. west to the axis of the Gulf Stream, and then following the axis of the Gulf Stream north to 31º N Lat., 79º 20’ W. Long. B3(c) would also move the southernmost boundary of the Florida East Coast closure north from 24º 00’ N Lat. to 24º 10’ N. Lat. between 81º 47’ and 81º 00’ W. Long. (Figure 2.3). This alternative would reopen these areas to PLL gear year-round. Alternative B3(d) would modify the existing DeSoto Canyon time/area closure boundary to allow PLL gear in areas seaward of the 2000 meter contour from 26º N. Lat., 85º 00’ W. Long., to 29º N. Lat., 88º 00’ W. Long. (Figure 2.3). B3(d) would reopen this area to PLL gear year-round.

The proportion of discarded swordfish versus the number of swordfish kept varied among the modifications to existing time/area closures (Table A.25 in Appendix A). Both alternatives B3(c) and B3(d) could have resulted in a larger proportion of discarded swordfish than alternatives B3(a) or B3(b) (Table A.25 in Appendix A). Minimizing the number of swordfish caught in B3(d) is important because the average swordfish size was significantly smaller in the area to be reopened (average size was 108 cm LJFL in the portion considered for reopening; $P = 0.03$; Table A.21 in Appendix A) compared to the area to remain closed (Figure A.2 in Appendix A; average size was 116 cm LJFL in the portion to remain closed; Table A.21 in Appendix A). In addition, the average swordfish size in B3(d) in the outside area was smaller than the minimum size limit of 119 cm LJFL (Table A.21 in Appendix A). There were also a lower proportion of BFT discards in the B3(a) and B3(b) modifications compared to B3(c) and B3(d) (Table A.25 in Appendix A). Although B3(c) could have resulted in an increase in the number of landed swordfish, yellowfin tuna, and bigeye tuna than either B3(a) or B3(b), it could have also increased the number of swordfish, bluefin, yellowfin and bigeye tuna discards (Table A.25 in Appendix A).

In terms of bycatch, B3(c) or B3(d) could result in the highest bycatch levels of white and blue marlin, and sailfish; almost 2.5 times as many white marlin, at least four times as many blue marlin, and at least ten times as many sailfish could be discarded in the B3(c) and B3(d) modifications compared to the B3(a) or B3(b) modification (Table A.24 in Appendix A). Such high levels of bycatch associated with B3(c) or B3(d) may have a larger negative ecological impact compared to B3(a) or B3(b); thus, NMFS only analyzed alternatives B3(a) and B3(b) in Chapter 4.

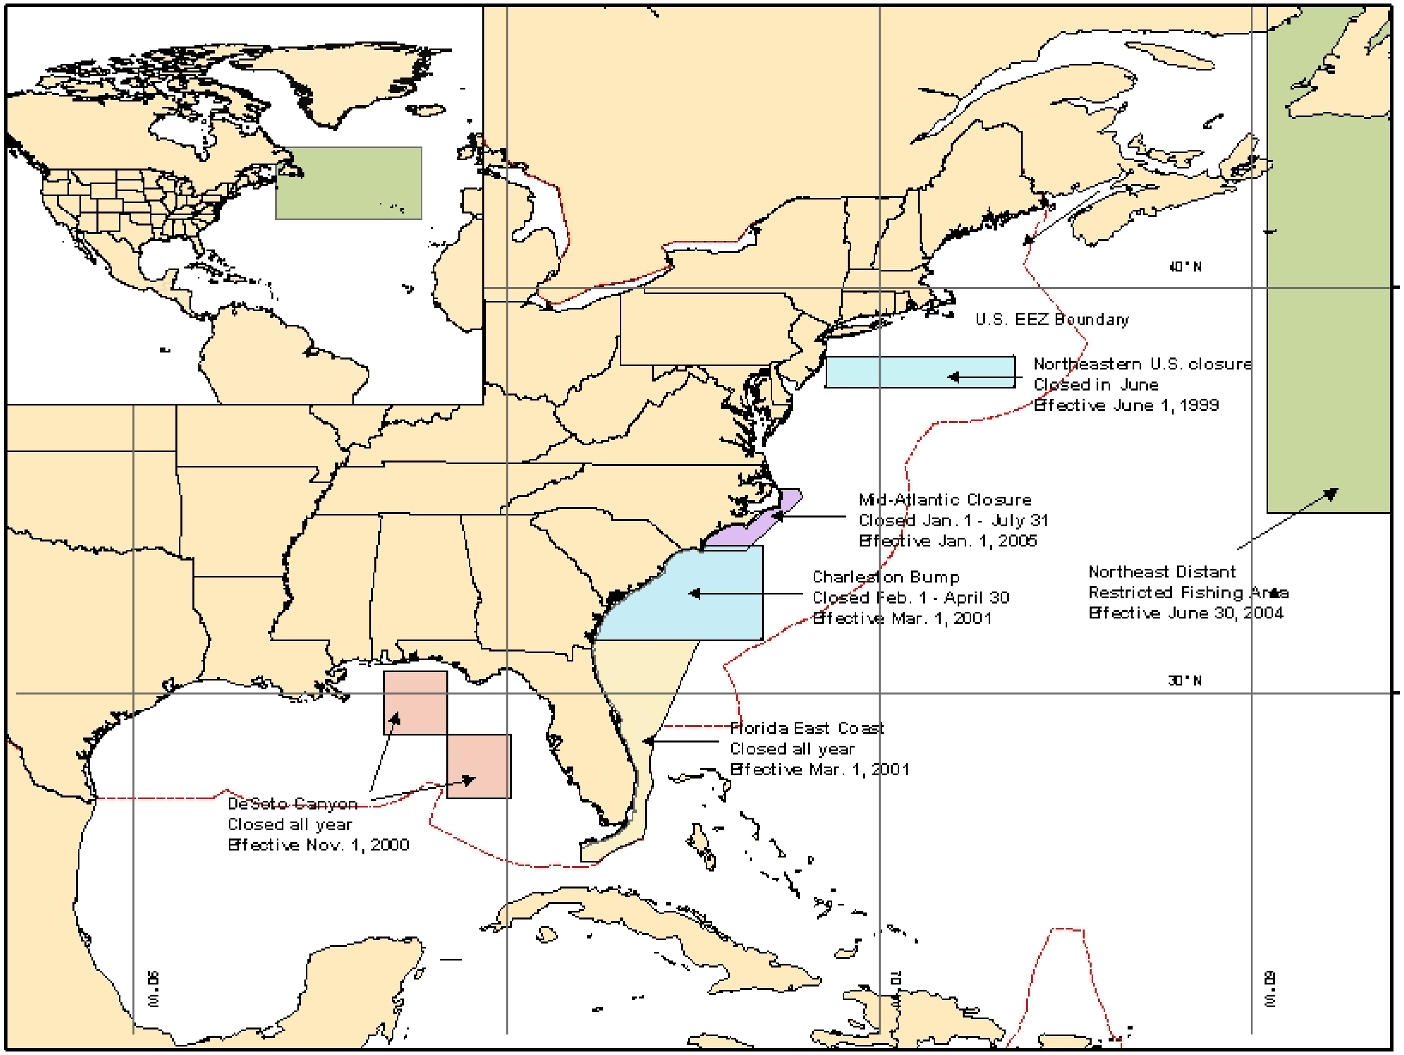

**Figure 2.1 Existing time/area closures in HMS fisheries.** Inset shows extent of the Northeast Distant restricted fishing area. All closures except the Mid-Atlantic are applicable to pelagic longline gear only. The Mid-Atlantic Closure is applicable to bottom longline gear only. Note: the Northeast Distant (NED) was a closed area to all vessels as of 2001. It became the NED Restricted Fishing Area on June 30, 2004 when it was opened to those participating in the NED experiment.

## 2.2 Rebuilding and Preventing Overfishing

### 2.2.1 Northern Albacore Tuna

In the October 1999 Report to Congress on the Status of U.S. Fisheries, NMFS identified the northern albacore tuna stock as overfished. The Magnuson-Stevens Act requires NMFS to develop a rebuilding plan for overfished stocks. Alternatives for developing a rebuilding plan for northern albacore tuna were presented and discussed in a proposed rule issued on May 24, 2000 (65 FR 33519). The alternatives considered included; no action, a unilateral U.S. action plan, and a ten-year international rebuilding program negotiated through ICCAT. NMFS requested comment on those rebuilding alternatives and commenters noted that a rebuilding program for northern albacore tuna must reflect the magnitude of current landings and consider year-to-year variability in the U.S. commercial and recreational fisheries. In the final rule, NMFS indicated that, in establishing the foundation for an international rebuilding program, it would work through ICCAT to adopt a target stock size together with a time frame for rebuilding that included flexibility (65 FR 77523, December 12, 2000).

Since the final rule, the U.S delegation to ICCAT has advocated a total allowable catch (TAC) for northern albacore tuna set at a level less than the current estimate of replacement yield (34,500 mt ww). Other ICCAT members have not shared the U.S. position that immediate catch reductions were needed to rebuild the spawning stock biomass to levels that would support MSY. Consequently, between 2000 and 2003, ICCAT adopted recommendations each year to set a TAC at the replacement yield level of 34,500 mt ww through 2006, together with country specific allocations in order to control compliance. In addition, the 1998 recommendation on limiting vessel capacity for northern albacore has remained in force. Irrespective of the established TAC, reported catches have been significantly below the replacement yield level in recent years. Major harvesters (European Union countries) have attributed the decline in catches to gear changes (shifting from banned gillnets to trolling) and to availability (fish concentrations further offshore under prevailing oceanographic conditions) rather than further declines in abundance. If true, the low catches in recent years may have allowed some rebuilding to occur.

As noted above, NMFS previously took comment on the following northern albacore rebuilding alternatives. Comments were again received on the following alternatives ending March 1, 2006.

Alternative C1 Maintain compliance with the current ICCAT recommendation (No Action)

Under Alternative C1, NMFS would continue to monitor U.S. northern albacore tuna fisheries to stay in compliance with the ICCAT-recommended annual U.S. TAC of 607 mt ww, however; NMFS would not actively pursue the development of an international rebuilding plan, or seek to establish the foundation for such a plan at future ICCAT meetings.

Alternative C2 Unilateral proportional reduction of United States northern albacore tuna fishing mortality

Alternative C2 would establish a reduction in fishing mortality of northern albacore tuna in U.S. fisheries. This would be a unilateral action setting a proportional reduction below the current TAC in an effort to begin rebuilding the northern albacore stock. A variety of measures designed to reduce mortality would be examined, including but not limited to: seasonal closures, closed areas, quota restrictions, size limits, and retention limits. Those measures found to be appropriate would be implemented as domestic regulation through separate rulemaking.

Alternative C3 *Establish the foundation with ICCAT for developing an international rebuilding program – Preferred Alternative*

This measure would incorporate an ICCAT northern albacore rebuilding program into this consolidated HMS FMP. Depending on the results of the scheduled 2007 stock assessment, the United States would, if warranted, seek an international northern albacore tuna rebuilding program with a target stock level, a time table, and reference points for progress. In order to rebuild the stock, if the 2007 assessment indicates a similar level of stock abundance below $B_{MSY,}$ ICCAT would likely have to set the TAC at replacement level or below. The U.S. landings alone, at around two percent, would likely not provide enough harvest reduction to rebuild the stock. Under alternative C3, the United States would continue to work through ICCAT to establish a stock size and rebuilding plan time frame consistent with the Magnuson-Stevens Act. Such an international rebuilding program should ensure rebuilding to a level capable of producing MSY with a target stock level, a timetable, and reference points. Once a plan was established, the United States would comply with ICCAT recommendation(s), with domestic regulatory action as necessary. Alternative C3 would not require any immediate domestic regulatory action.

### 2.2.2 Finetooth Sharks

The following alternatives explore a range of management options available to address overfishing of finetooth sharks. The 2002 stock assessment for Small Coastal Sharks (SCS) found that overfishing was occurring on finetooth sharks. A more detailed description of the 2002 SCS assessment can be found in Section 3.2.5.

Alternative D1 Maintain current regulations (No Action)

This alternative would maintain fishing mortality at current levels. Finetooth sharks are managed for recreational and commercial fisheries within the SCS species complex. Commercial fisheries are managed under a limited access permitting system where new entrants to the fishery must obtain a previously held permit and transfer it to their vessel, subject to upgrading restrictions. There are five vessels that target sharks with drift gillnet or strikenet gear and these vessels are subject to extensive observer coverage. There is no SCS trip limit for directed permit holders; however, incidental permit holders are limited to 16 SCS and pelagic sharks combined per vessel per day. Between 1999 and 2004, commercial landings of SCS ranged from 204-330 mt dw, well below the quota established for SCS (Table 4.2). Most finetooth sharks are landed by vessels targeting species other than sharks, with gillnet gear, in the

South Atlantic region. Recreational anglers must possess an HMS Angling permit and are subject to a bag limit of one shark (including finetooth shark) greater than 54 inches FL (137 cm) per vessel per day. The Marine Recreational Fisheries Statistics Survey (MRFSS) and the Texas Parks and Wildlife Service estimated that 14,811 finetooth sharks were landed between 1999 and 2005.

Alternative D2 Implement commercial management measures to reduce fishing mortality of finetooth sharks

This alternative would implement management measures to reduce finetooth shark fishing mortality in commercial fisheries targeting sharks. These measures would affect all vessels in possession of a Federal limited access shark permit. These actions may include any combination of the following measures, including: a directed trip limit for SCS, gillnet gear restrictions, prohibiting the use of gillnet gear for landing sharks, reduced soak time for gillnets, and reducing the overall SCS quota.

Alternative D3 Implement recreational management measures to reduce fishing mortality of finetooth sharks

This alternative would implement measures aimed at reducing fishing mortality of finetooth sharks in HMS recreational fisheries. These measures would affect all vessels in possession of a Federal HMS Angling category permit, CHB permit, and/or General category permit that target finetooth sharks. This alternative may require the use of circle hooks when targeting SCS, and/or increasing the minimum size for retention of finetooth sharks. Currently, anglers may retain one shark over 54 inches (137 cm) per vessel per trip and are permitted to use circle and J-hooks. This alternative would not affect the minimum size for possession of other sharks.

Alternative D4 *Identify sources of finetooth fishing mortality to target appropriate management actions (Preferred Alternative)*

Landings data from dealer reports, compared to observer data from the Directed Shark Gillnet Fishery Observer Program (DSGFOP) indicate that the five vessels currently targeting sharks with drift or strike gillnets are not landing a significant portion of the total catch of finetooth sharks (Tables 4.1 and 4.2). Furthermore, most of these vessels also possess a Spanish mackerel permit. There are also additional vessels that are permitted to deploy gillnet gear and possess both a commercial shark limited access permit and a Spanish mackerel permit. These vessels were not previously considered to be targeting sharks and are not subject to observer coverage because they were either targeting non-HMS or not fishing gillnets in a strike or drift fashion.

This alternative would implement a plan to prevent overfishing of finetooth sharks that entails identifying sources of finetooth shark fishing mortality in commercial (gillnet and other) and recreational fisheries that may not be targeting sharks specifically, but landing them incidentally to other species. Furthermore, this alternative would also result in improved collaboration among management entities; this collaboration may be necessary to prevent overfishing of finetooth sharks because fisheries managed by other management entities may be contributing to fishing mortality. Additional data collected may also be beneficial to the upcoming stock assessment for SCS beginning in 2007. Specific activities that may be included in the Agency's plan for preventing overfishing and included in this alternative may include, but would not be limited to: contacting states, Regional Fishery Management Councils, and Interstate Marine Fisheries Commissions to determine which fisheries may be landing finetooth sharks; contacting state employees responsible for processing finetooth shark landings data to understand data management protocols and procedures between states and obtain additional landings data; including finetooth sharks as a select species for bycatch sub-sampling in the Gulf of Mexico shrimp trawl fishery; selecting vessels that deploy sink gillnet gear and/or target non-HMS for observer coverage under the DSGFOP; analyzing Federal logbook data to determine seasonality, locations, and which non-HMS are landed on trips that also harvest finetooth sharks; exploring collaborative management measures with the South Atlantic Fishery Management Council to address the overlap between shark and Spanish mackerel gillnet fisheries; and, implementing shark identification workshops (alternative A9) for dealers so that they might become more proficient at identifying finetooth sharks (Table 2.1).

**Table 2.1 Summary and status of activities, anticipated results, and associated timelines for preventing overfishing of finetooth sharks.**

| Activity | Anticipated Results | Status | Timeline |
|---|---|---|---|
| Send letters to Regional Fishery Management Councils and Interstate Marine Fisheries Commissions to determine sources of finetooth mortality | Expand information on fisheries that are landing finetooth sharks within the purview of Councils, Commissions, and state agencies; Obtain additional data for SCS assessment; attain points of contacts with the various Councils, states, and Commissions regarding identification of finetooth landings; understand how and where finetooth sharks are being reported and the availability of additional landings data | Contacts for ASMFC and GMFMC attained; additional information on fisheries landing finetooth sharks in Federal waters was obtained | 06/2005 (*letters sent to Gulf and South Atlantic Councils and Gulf and Atlantic States Marine Fisheries Commissions seeking data/information on finetooth landings)*<br>04/2006 – ongoing (*collaboration/follow-up with SAFMC initiated because of overlap between Spanish mackerel and shark fisheries; issues surrounding potential management of kingfish in Federal waters*) |
| Expand DSGFOP to include vessels targeting non-HMS and/or using sink gillnet gear | Increase landings information on finetooth sharks landed with gillnet gear in Federal waters of the South Atlantic, expand available data for SCS assessment | In 2005, 88 sets observed on 30 trips from 8 vessels not targeting HMS or fishing with sink gillnets | 2005 (*pilot program, expanded DSGFOP to include sink-gillnet fishermen, vessels not targeting HMS*)<br>2006 - ongoing (*continue inclusion of additional vessels in selection for coverage under DSGFOP*) |
| Contact individual states (TX to NC) to determine data management protocols, fisheries | Obtain additional information on finetooth shark landings, fisheries deploying gillnets in state waters, data management and reporting; Attain state | Contacted state employees in AL, TX, NC, FL, LA, MS, and GA, SC.<br>Additional landings | 2006 - ongoing (*inclusion of finetooth sharks in any state observer program for bycatch sampling*) |

| Activity | Anticipated Results | Status | Timeline |
|---|---|---|---|
| interacting with finetooth, regulations, etc. | contacts for future measures to prevent overfishing of finetooth sharks | data attained from FL, AL, LA | |
| Include finetooth sharks as a select species in the Shrimp Trawl Fishery Observer Program in the Gulf of Mexico | Increase bycatch landings information in the GOM shrimp trawl fishery, expand bycatch data for SCS assessment | Included finetooth sharks as a select spp. for bycatch sampling on shrimp trawl vessels in GOM | 2006 - ongoing |
| Implement identification workshops for shark dealers (Alternative A9) | Improve species identification skills; improve General Canvass (dealer) data reports | Implementation of Alternative A9 in 2007; include all Federal shark dealer permit holders | 2007 - ongoing |
| SCS stock assessment | Update information on the status of finetooth sharks in the Atlantic Ocean | First data review workshop in early 2007 | 2007 |
| Target appropriate management measures as necessary | Based on stock assessment and investigating other sources of mortality, implement commercial and/or recreational management measures as necessary to prevent overfishing | | 2007 - 2008 |

*Other alternatives considered but not further analyzed at this time*

Alternative D5 Prohibit landings of finetooth sharks in commercial and recreational fisheries.

This alternative would add finetooth sharks to the prohibited species list for commercial and recreational fisheries. Federally permitted commercial and recreational fishermen would not be able to land and/or possess finetooth sharks under this alternative. Finetooth sharks would need to meet at least two of the four criteria defined under 50 CFR Part 635 for inclusion of the species to the prohibited species list for Atlantic sharks. The existing criteria are: (1) there is sufficient biological information to indicate the stock warrants protection, such as indications of depletion or low reproductive potential or the species is on the ESA candidate list; (2) the species is rarely encountered or observed caught in HMS fisheries, (3) the species is not commonly encountered or observed caught as bycatch in fishing operations, or (4) the species is difficult to distinguish from other prohibited species (*i.e.*, look alike issue). Finetooth sharks do not meet any of the criteria necessary to be considered a prohibited species at this time.

During the development of Amendment 1 to the Fishery Management Plan for Atlantic Tunas, Swordfish, and Sharks, the Agency considered the addition of finetooth to the list of prohibited species and concluded:

"This alternative would have limited ecological impacts as finetooth sharks are common bycatch in non-HMS fisheries and prohibiting them will not prevent their capture. A reduction in finetooth shark landings in HMS fisheries may not significantly reduce mortality because they are only a small component of total landings. This alternative may help to reduce mortality of this species but could also increase waste and discards...In regard to alternative I6 [prohibited species listing criteria], finetooth sharks are not depleted and are commonly caught in HMS and non-HMS fisheries. Therefore, this species does not appear to meet the criteria selected under alternative I6, at this time".

The Agency does not have any new information at this time that would alter this conclusion. Thus, this alternative was not further analyzed at this time. As more information is collected, NMFS may re-consider if necessary.

### 2.2.3 Atlantic Billfish

Atlantic blue and white marlins have been identified as overfished with overfishing continuing. West Atlantic sailfish are considered overfished. The status of blue and white marlin is characterized by reduced or severely reduced biomass levels and high fishing mortality rates. In 2002, NMFS conducted an Endangered Species Act (ESA) status listing review for Atlantic white marlin and determined that a listing was not warranted at that time. Another ESA status listing review for Atlantic white marlin is scheduled in 2007, and additional conservation steps taken in advance of that review would be relevant to status review deliberations. Domestically, directed billfish fishing effort has been reserved for the recreational fishing sector since 1988, when possession by pelagic longline vessels and sales of Atlantic billfish species were prohibited. Based on ICCAT data, the United States' landings (landings and dead discards) of Atlantic blue and white marlin averaged 2.4 percent and 4.5 percent (respectively) of aggregate Atlantic-wide landings for these species, as reported to ICCAT for the period 1999-2004. U.S. landings of West Atlantic sailfish averaged 8.6 percent of aggregate West Atlantic-wide sailfish landings, as reported to ICCAT for the period 1999-2004.

The following alternatives represent the range of options that NMFS is considering to reduce the recreational fishery's contribution to overfishing and to improve data collection. Please see section 2.1.2 for alternatives considered to address commercial billfish bycatch issues. The alternatives include gear restrictions, landings restrictions, and data collection requirements.

Alternative E1 Retain existing regulations regarding recreational billfish fishing, including permit requirements, minimum size limits, prohibited species, landing form, allowable gear, and reporting requirements (No Action)

Alternative E1 would maintain the *status quo* in the domestic Atlantic recreational billfish fishery. As such, this alternative retains all existing regulations regarding recreational billfish fishing in the Atlantic Ocean, including permit requirements, minimum size limits, prohibited species, catch and release fishery management program, landing form, allowable gear, and reporting requirements, unless specifically modified during this rulemaking.

Alternative E2 Effective January 1, 2007, limit all participants in Atlantic HMS recreational fisheries to using only non-offset circle hooks when using natural baits or natural bait/artificial lure combinations

Alternative E2 would require the use of non-offset circle hooks in all segments of HMS recreational fisheries, for all species, whenever natural baits or natural bait/artificial lure combinations are used, beginning on January 1, 2007. This includes HMS Angling category permitted vessels, Charter/Headboat permitted vessels on for-hire trips, and all General category permitted vessels participating in registered HMS tournaments. Circle hooks are defined in 50 CFR §635.2 as "a fishing hook originally designed and manufactured so that the point is turned perpendicularly back to the shank to form a generally circular, or oval, shape." Natural bait/artificial lure combinations would include, but are not limited to, rigs such as natural baits used in combination with artificial hoods, heads, and/or skirts. This alternative would allow the use of J-hooks with artificial lures.

Alternative E3 *Effective January 1, 2007, limit all HMS permitted vessels participating in Atlantic billfish tournaments to deploying only non-offset circle hooks when using natural bait or natural bait/artificial lure combinations – Preferred Alternative*

Alternative E3 would require the use of non-offset circle hooks by anglers fishing from HMS permitted vessels, or vessels required to be permitted, participating in Atlantic billfish tournaments whenever natural bait or natural bait/artificial lure combinations are used, effective January 1, 2007. Any tournament that has an award category, or awards points or prizes for Atlantic billfish is considered a billfish tournament. Circle hooks are defined in 50 CFR §635.2 as "a fishing hook originally designed and manufactured so that the point is turned perpendicularly back to the shank to form a generally circular, or oval, shape." Natural bait/artificial lure combinations would include, but are not limited to, rigs such as natural baits used in combination with artificial hoods, heads, and/or skirts. This alternative would allow the use of J-hooks with artificial lures in tournaments. This alternative includes a minor technical clarification relative to preferred alternative E3, as presented in the Draft Consolidated HMS FMP. As described more fully in Chapter 4, the changes are intended to clarify that circle hook use is only required aboard HMS permitted vessels participating in Atlantic billfish tournaments when deploying natural baits or natural bait/artificial lure combinations. The phrasing of alternative E3 in the Draft Consolidated HMS FMP was sufficiently vague to allow other interpretations of which anglers may be affected by this alternative. This technical clarification has no effect on the impacts of the alternative, as only permitted HMS vessels may fish for, catch, or retain Atlantic billfish, and alternative E3 in the Draft Consolidated HMS FMP was analyzed from the vantage point of applying only to HMS permitted vessels.

Alternative E4(a) Increase the minimum legal size for Atlantic white marlin to a specific size between 68 and 71 inches LJFL (172 - 180 cm)

Alternative E4(a) would increase the minimum legal size for Atlantic white marlin to a specific size between 68 and 71 inches LJFL (172 - 180 cm) to reduce U. S. landings and/or mortalities, as appropriate. The sizes presented represent the upper and lower bounds of the sizes analyzed and available for selection, and as such, do not represent consideration of a "slot limit."

Alternative E4(b) Increase the minimum size for blue marlin to a specific size between 103 and 106 inches LJFL (261 – 269 cm)

Alternative E4(b) would increase the minimum size for blue marlin to a specific size between 103 and 106 inches LJFL (261 – 269 cm) to reduce U.S. landings and/or mortalities, as appropriate. The sizes presented represent the upper and lower bounds of the sizes analyzed and available for selection, and as such, do not represent consideration of a "slot limit."

Alternative E5 Implement a recreational bag limit of one Atlantic billfish per vessel per trip

Alternative E5 would implement a recreational bag limit of one Atlantic billfish per vessel per trip. No more than one Atlantic billfish would be allowed to be possessed, retained, or landed on, or by, a vessel regardless of the length of the trip.

Alternative E6 *Effective January 1, 2007, Implement ICCAT Recommendations on Recreational Marlin Landings Limits – Preferred Alternative*

Alternative E6 would codify ICCAT recommendations pertaining to recreational marlin landing limits and implement domestic compliance mechanisms. Specifically, this includes an annual landings-limit of 250 recreationally caught Atlantic blue and white marlin, combined, as per ICCAT recommendations 00-13 and 04-09. To provide for maximum utilization of the U.S. recreational Atlantic marlin landing limit without exceeding it, this alternative would allow NMFS to increase the legal minimum size of blue and/or white marlin, as appropriate. The anticipated effect of an in-season minimum size increase would be to slow landings, if necessary, and thereby prevent a shift to catch and release fishing only. Under this alternative, the proposed size range that would be made available to NMFS for in-season management actions is from 117 to 138 inches for Atlantic blue marlin and 70 to 79 inches for Atlantic white marlin. The need for action and the specific minimum size temporarily implemented would be based upon a review of observed landings, time remaining until conclusion of the current fishing year, current and historical landings trends, and any other relevant factors. As a backstop to ensure that the U.S.'s actions remain consistent with the ICCAT landing limit, the fishery would become catch and release only for the remainder of a fishing year if the landing limit were achieved. If marlin minimum sizes are increased to slow landings during a given fishing year, they would revert back to the previous minimum size at the start of the next fishing season. Consistent with ICCAT recommendations, NMFS would subtract any overharvest from the subsequent fishing year's landing limit, and could carry forward any underharvest to the subsequent fishing year.

Alternative E7 Effective January 1, 2007 – December 31, 2011, allow only catch and release fishing for Atlantic white marlin

Alternative E7 would allow only catch and release fishing for Atlantic white marlin. Possession, retention, and landings of Atlantic white marlin would be prohibited at all times and under all circumstances. This provision would expire five years from the effective date unless specifically extended by NMFS. This alternative was preferred in the Draft Consolidated HMS FMP. As further described in Chapter 4, NMFS is not selecting this alternative as a preferred alternative in the final Consolidated HMS FMP, but may consider it in a future rulemaking, as necessary and appropriate.

Alternative E8 Effective January 1, 2007 – December 31, 2011, allow only catch and release fishing for Atlantic blue marlin

Alternative E8 would allow only catch and release fishing for Atlantic blue marlin. Possession, retention, and landings of Atlantic white marlin would be prohibited at all times and under all circumstances. This provision would expire five years from the effective date unless specifically extended by NMFS

*Other billfish alternatives considered but not further analyzed at this time*

Alternative E9 Implement a mandatory Atlantic HMS tournament permit

Alternative E9 would replace the current tournament registration system with a mandatory tournament permit. A separate permit would be required for each tournament on an annual basis. Tournament permit applications would be required to be received 45 days in advance of the tournament to allow NMFS time to process the permit and select tournaments for reporting, if appropriate. This alternative would not alter reporting requirements. NMFS has determined that improvements to tournament registration, data collection, and enforceability that could be achieved under this alternative can be achieved with significantly less burden to the public and government through implementation of regulatory clarifications contained elsewhere in this document. Please see the Section 2.3.4 Regulatory Housekeeping for addition details. Therefore, this alternative is not further analyzed in this rulemaking, but maybe considered, if appropriate and necessary, in a future rulemaking.

## 2.3 Management Program Structure

### 2.3.1 Atlantic Bluefin Tuna Quota Management

#### *2.3.1.1 BFT Quota Management in the General and Angling Categories*

The following alternatives explore different possibilities for amending/clarifying the annual BFT quota allocation schemes in both the General and Angling categories. Currently, ICCAT recommends an annual Total Allowable Catch (TAC) of BFT for the United States in the western Atlantic management area. NMFS implements these ICCAT recommendations, as required by ATCA, by dividing the annual U.S. BFT TAC among several domestic quota categories based on allocation percentages established in the 1999 FMP. In some categories, including the General and Angling categories, NMFS further subdivides these domestic category allocations into subquotas (*i.e.*, on a temporal, geographic, and/or BFT size class basis) to further meet the objectives of the Magnuson-Stevens Act, ATCA, and the 1999 FMP. Not all of the alternatives described below are mutually exclusive.

Alternative F1 Maintain the time-periods, subquota allocations, and geographic set-asides for the General and Angling categories as established in the 1999 FMP (No Action)

This alternative would maintain the current General category time-period subquota allocation scheme, as stated in the 1999 FMP, and would require an FMP amendment to adjust the time-period subquota allocation percentages in the future. This sub-allocation scheme divides the annual General category quota in three distinct time-periods and one geographic set-aside. The New York Bight geographic set-aside (Figure 2.7) is allocated ten metric tons (mt) whole weight on an annual basis. Once this amount is deducted from the overall General category quota, the remaining quota is divided among three time-periods and is allocated to each time-period as follows: 60 percent to June through August, 30 percent to September, and 10 percent to October through January (Figure 2.8).

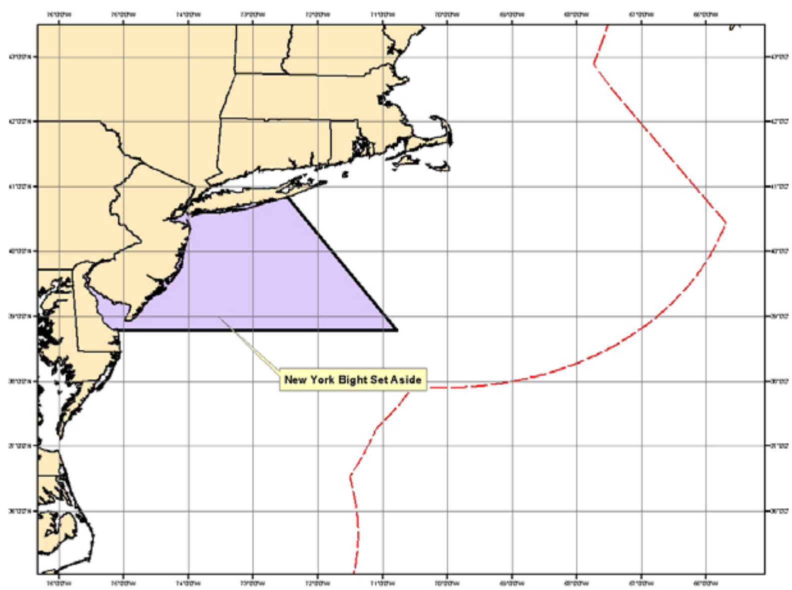

**Figure 2.7 The New York Bight set-aside is defined as an area comprising the waters South and West of a straight line originating at a point on the southern shore of Long Island, NY, at 72º 27' W. Long. (Shinnecock Inlet) and running South southeast 150º true, and north of 38º 47' N. Lat.**

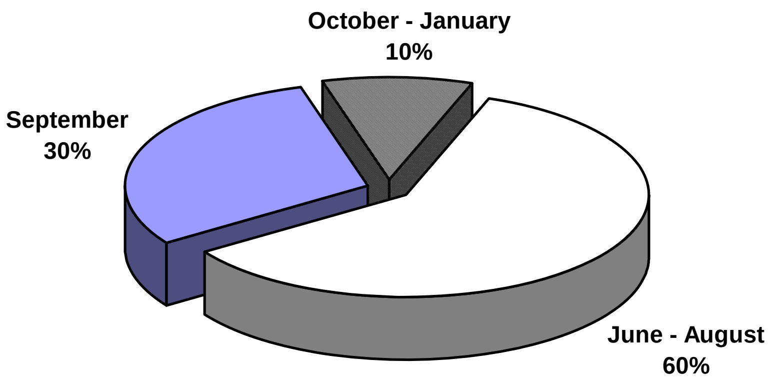

**Figure 2.8 Alternative F1: No Action. Suballocation of the BFT General Category Quota among the current three time-periods. New York Bight set-aside is subtracted from the General Category quota and then the time-period allocations are determined.**

This alternative would maintain the process NMFS currently uses to account for the ICCAT recommendations regarding the tolerance limit of school BFT and the Northeast Distant (NED) Statistical Area set-aside. The ICCAT recommendation regarding school BFT states that contracting parties, non-contracting parties, entities and fishing entities may grant tolerances to capture western Atlantic BFT either weighing less that 30 kg, or in the alternative having a fork length less than 115 cm provided they limit the take of these fish so that the average over each four-consecutive-year quota balancing period is no more than eight percent by weight of the total BFT quota on a national basis, and institute measures to deny economic gain to the fishermen from such fish. ICCAT has adopted an additional recommendation stating that the United States shall receive a quota (of catch that can be retained) of 25 mt to account for bycatch related to its directed longline fisheries in the vicinity of the management area boundary. NMFS defined “in the vicinity of the management area boundary” as the NED Statistical Area (68 FR 56783, October 2, 2003).

As the NED Statistical Area recommendation is more recent than the school BFT tolerance limit, NMFS has not accounted for this additional allocation in the calculations used to formulate the school tolerance BFT. Therefore, under this alternative, the United States would deduct the quota attributed to the NED Statistical Area before applying the eight percent school size-class BFT tolerance limit to the U.S. overall quota, rather than applying the eight percent to the total U.S. BFT quota.

This alternative would maintain the North/South Angling category dividing line (Figure 2.9). This dividing line is intended to provide a more equitable geographic and temporal distribution of recreational fishing opportunities by separating each BFT size-class subquota into two geographical regions, the northern area (allocated 47.2 percent of the size-class subquotas) and the southern area (52.8 percent of the size-class subquotas).

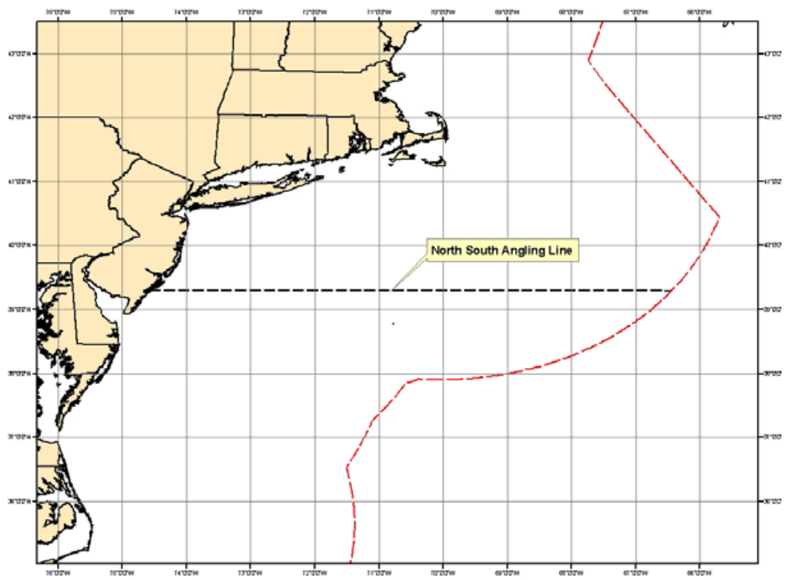

**Figure 2.9 The Angling category North/South dividing line, located at 39º 18’ N. Lat. (Great Egg Inlet, NJ).**

Alternative F2 Establish General category time-periods, subquotas, and geographic set-asides annually via framework actions

This alternative would amend the status quo process that establishes the General category time-periods and associated subquotas. Under this alternative, General category time-periods and/or the subquota allocated to each time-period, as well as any geographic set-asides, would be established annually via a regulatory framework action (versus an FMP amendment as described under Alternative F1). This alternative would revise the detailed language regarding General category time-periods, subquota allocations, and geographic set-asides contained in the 1999 FMP to be more general. The specific details pertaining to management of the General category would be established each year in the annual regulatory framework action. This alternative attempts to address the inherent variability in the General category BFT fishery from one year to the next, and would require the regulatory framework action to be finalized prior to the start of the season, thereby establishing General category time-periods and associated subquotas before the fishery commences.

Factors that would be considered prior to establishing the annual General category time-periods, associated subquotas, and/or geographic set-asides may include, but would not be limited to, protected species interactions and bycatch rates, historic landings, total landings reported at the end of the season, weather conditions, levels of effort, the amount of unharvested quota rolling over from the previous fishing year, and the projected ability of the vessels to harvest the subquotas.

Alternative F3 *Amend the management procedures regarding General category time-periods, subquotas, as well as geographic set-asides to allow for future adjustments to take place via a regulatory framework action – Preferred Alternative*

This alternative would amend the status quo management procedures which establish and adjust the General category time-periods, subquotas, as well as geographic set-asides. More specifically, this alternative would revise the detailed language regarding General category time-periods, subquota allocations, and geographic set-asides contained in the 1999 FMP to be more general, similar to Alternative F2. However, under this alternative, the specific details pertaining to management of the General category would be established in the regulatory text implementing the consolidated FMP, versus established annually (as in Alternative F2), thereby providing a level of consistency from one year to the next. By moving the specific language from the FMP to the implementing regulations, NMFS would be able to provide consistent time-periods and subquotas while also gaining the ability to amend these General category time-periods, subquota allocation percentages, and geographic set-asides, if deemed necessary, via a regulatory framework action, versus an FMP amendment.

Additionally, because the General category baseline quota, time-periods, and associated subquotas would be contained in the implementing regulations, the annual BFT specification process would not be necessary for the fishery to commence on the first day of the fishing year. Factors that may warrant future adjustments may include, but may not be limited to, ICCAT recommendations that modify BFT management measures, shifts in protected species interactions and bycatch rates, consideration of historic allocations and landings, stability and predictability of quotas, total landings reported, weather conditions, levels of effort, the amount of unharvested quota rolling from one year to the next, and the projected ability of the vessels to harvest the subquotas. If the specific management measures contained in the regulatory text need to be changed, then an appropriate analytical document (*i.e.*, EA or EIS, RIR, IRFA, etc.) may need to accompany the proposed and final rule in the regulatory amendment. However, as long as the ICCAT recommended annual U.S. BFT quota remains consistent, and the established General category time-period subquota allocation percentages are specified in whole weight, the regulatory, environmental, social, and economic analyses conducted for the consolidated HMS FMP would constitute the supporting documentation for the annual regulatory framework action.

This alternative would also amend the actual General category time-periods as well as the corresponding subquota allocation percentages for each time-period. These subalternatives would support the preferred alternative in Section 2.3.2, which would adjust management of all HMS fisheries to a calendar year basis, by providing separate time-period subquota for December and January, ensuring that the time-periods do not span two calendar years. The status quo General category time-periods and subquotas are described in Alternative F1. The range of sub-alternatives analyzed in this document are intended to further meet the objectives of the Magnuson-Stevens Act, ATCA, as well as the consolidated HMS FMP, and are drafted in accordance with the preferred CY/FY alternatives contained in Section 2.3.2. These alternatives specifically address public comments received during the scoping period of this action as well as the North Carolina Department of Marine Fisheries' (NCDMF) Petition for Rulemaking (see Notice of Receipt of Petition, 67 FR 69502, November 18, 2002). The sub-alternatives are as follows:

Alternative F3(a) Establish equal monthly General category time-periods and subquotas (June-Jan; 12.5 percent each)

This sub-alternative would remove the New York Bight set-aside allocation and divide the coast-wide General category season into eight distinct time-periods that correspond to each month from June through January. The coast-wide General category quota would be allocated in equal amounts among all eight time periods, specifically 12.5 percent to each time-period (Figure 2.10). This alternative was designed to provide an opportunity to harvest an equal amount of quota during all eight months of the General category BFT season.

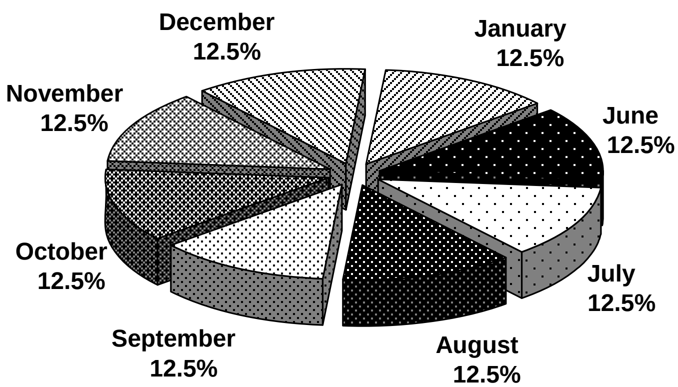

**Figure 2.10 Alternative F3a: Equal General category subquota allocation percentages for each month of the BFT fishing season.**

Alternative F3(b) Revise General category time-periods and subquotas to allow for a formalized winter fishery (June-Aug, 54 percent; Sept, 26.5 percent; Oct-Nov, 9 percent; Dec, 5.2 percent; and Jan, 5.3 percent)

This sub-alternative would remove the New York Bight set-aside allocation and divide the coast-wide General category season into five distinct time-periods that correspond with traditional fishing patterns in the New England region, yet are slightly modified to reflect recent trends in the fishery and provide for a formal winter fishery in the South Atlantic region. Historically, the coast-wide General category BFT fishery was prosecuted in the waters off New England during the summer and early fall months. However, recent trends in this coast-wide fishery reflect a shift in the availability of commercial size BFT, both geographically and temporally, to the South Atlantic area. This alternative is intended to achieve optimum yield from the General category quota while providing fair and equitable fishing opportunities to General category participants regardless of geographical location. The time-periods would consist of June through August, September, and October through November, December, and January. This alternative would also establish time-period subquota allocation percentages as follows: 54 percent (June through August), 26.5 percent (September), 9 percent (October through November), 5.2 percent (December) and 5.3 percent (January) (Figure 2.11).

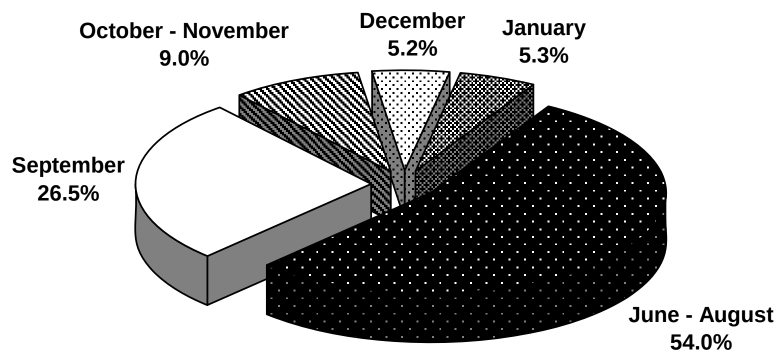

**Figure 2.11 Alternative F3b: Proposed General category time-period subquota allocation percentages.**

Alternative F3(c) *Revise General category time-periods and subquotas to allow for a formalized winter fishery (June-Aug, 50 percent; Sept, 26.5 percent; Oct-Nov, 13 percent; Dec, 5.2 percent; and Jan, 5.3 percent) – Preferred Alternative*

This sub-alternative would remove the New York Bight set-aside allocation and divide the coast-wide General category season into five distinct time-periods, June through August, September, October through November, December, and January. This alternative would shift slightly more quota from the start of the season to the October through November fishery (relative to Alternative F3(b)) where demand has been increasing in recent years, and to the December and January time-periods (relative to Alternative F1) providing for a formal winter BFT fishery in the South Atlantic region. As described in Alternative F3(b), the historical General category BFT fishery was primarily prosecuted in the waters off New England during the summer and early fall months. This resulted in a General category time-period and subquota allocation scheme heavily weighted to the New England fishery (*i.e.*, See Alternative F1 for the status quo). The time-periods, and associated subquotas, of this alternative would allocate fishing privileges to further achieve optimum yield without excluding traditional participants in the fishery. Thus, this alternative would establish time-period subquota allocation percentages as follows: 50 percent (June through August), 26.5 percent (September), 13 percent (October through November), 5.2 percent (December), and 5.3 percent (January) (Figure 2.12).

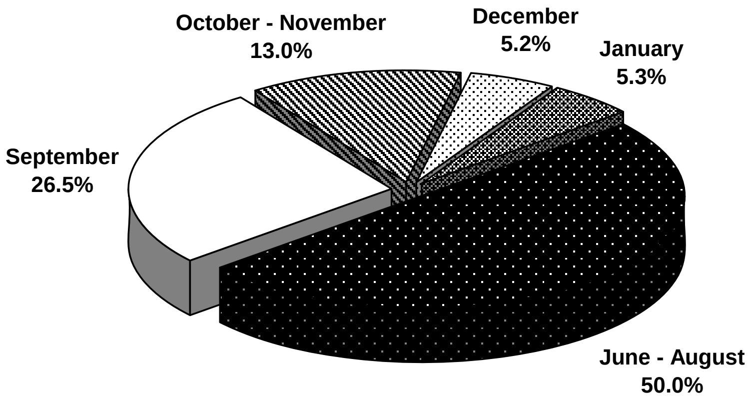

**Figure 2.12 Alternative F3c: Proposed General category time-period subquota allocation percentages.**

Alternative F3(d) Revise General category time-periods and subquotas to allow for a formalized winter fishery (June-Aug, 38.7 percent; Sept , 26.6 percent; Oct-Nov, 13 percent; Dec, 10.8 percent; and Jan, 10.9 percent)

This sub-alternative would also remove the New York Bight set-aside allocation and divide the coast-wide General category season into the same five distinct time-periods referred to in sub-alternatives F3(b) and F3(c). However, this alternative's time-period subquota allocation percentages would provide the greatest opportunity for the winter BFT fishery and specifically embody the subquota allocation requested in the NCDMF Petition for Rulemaking. This alternative would establish time-period subquota allocation percentages as follows: 38.7 percent (June through August), 26.6 percent (September), 13 percent (October), 10.8 percent (December), and 10.9 percent (January) (Figure 2.13).

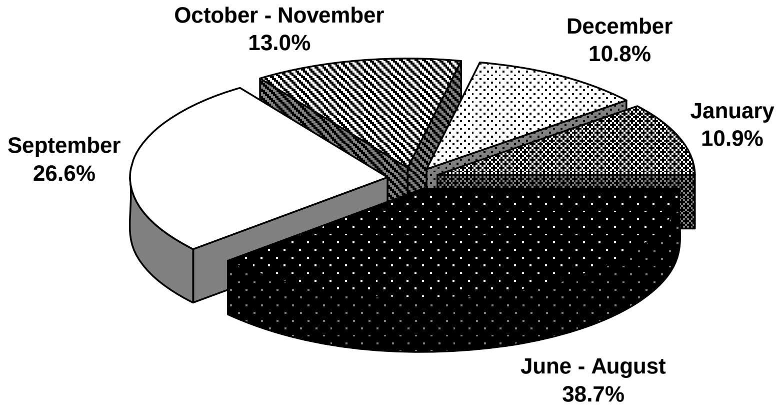

**Figure 2.13 Alternative F3d: Proposed General category time-period subquota allocation percentages embodying the NCDMF Petition for Rulemaking.**

Alternative F4 *Clarify the procedures for calculating the Angling category school size-class BFT subquota allocation – Preferred Alternative*

This alternative would clarify the procedure for calculating the ICCAT-recommended school size-class BFT tolerance for the Angling category quota. The eight percent tolerance limit would be calculated from the U.S. BFT quota to determine the school size-class allowance for the Angling category. Then, the NED Statistical set-aside allocation would be deducted from the remaining U.S. BFT quota. This clarification would implement procedures for calculating the eight percent tolerance limit to be more consistent with the actual language from the ICCAT recommendation and would result in a slight increase of the school size class BFT quota by approximately 0.02 percent.

This alternative has been slightly modified from that proposed in the draft HMS FMP. This preferred alternative modifies the proposed alternative in the draft FMP by retaining the North/South Angling category dividing line located at 39º 18 minutes N. latitude (Great Egg Inlet, NJ) (Figure 2.9). This dividing line is intended to provide a more equitable geographic and temporal distribution of recreational fishing opportunities by separating each BFT size-class subquota into two geographical regions, the northern area (allocated 47.2 percent of the size-class subquotas) and the southern area (52.8 percent of the size-class subquotas). This management tool was originally intended to ensure reasonable recreational fishing opportunities in all geographic areas without risking overharvest of the Angling category quota. While this line allows NMFS to allocate different retention limits based on the migratory pattern of BFT, the effectiveness of this management tool depends on NMFS gathering recreational BFT landings information in a timely fashion to support real-time management decisions.

#### *2.3.1.2 Annual BFT Quota Adjustments*

In 1991, ICCAT recommended that if the catch of a Contracting Party exceeds its annual or biannual scientific monitoring quota, then in the biannual period or year following reporting of that catch to ICCAT, that Contracting Party will reduce its catch to compensate in total for that overage. Such a reduction will be applied to the domestic catch category of the applicable Contracting Party of the overage (ICCAT 91-1). This recommendation was revised in 1998 to state that unused quota or overage from the previous year shall be added or subtracted, as appropriate, to the current year's catch that can be retained (ICCAT 98-7). The intent of the following alternatives is to streamline the annual BFT quota adjustment process, including the allocation of baseline quotas as well as adjusting those quotas based on the previous years under/overharvests.

The U.S. BFT quota is allocated to specific domestic quota categories via allocation percentages contained in the 1999 FMP. The annual BFT specifications quantify the baseline allocation for each domestic quota category, measured in whole weight (metric tons), by calculating the allocation percentages against the recommended U.S. BFT quota. These percentage shares were based on allocations that had been developed by NMFS over several years. Under all of the subsequent alternatives, the allocation of the U.S. BFT quota will remain consistent with those baseline percentages established in the 1999 FMP. These percentages are as follows: General - 47.1 percent; Angling - 19.7 percent; Harpoon - 3.9 percent; Purse Seine - 18.6 percent; Longline - 8.1 percent; and Trap - 0.1 percent. The remaining 2.5 percent of the

BFT landings quota will be held in the Reserve category (Figure 2.8). These domestic quota category percentages will remain unchanged as codified in the consolidated HMS FMP and would require an FMP amendment to change them in the future. However, revisions to the General category time-period subquota allocation scheme are being considered in Section 2.3.1.1.

Alternative F5 Maintain the annual BFT quota specification process and the under/overharvest procedures within individual domestic quota categories and individual vessels in the Purse seine category (No Action)

This alternative would maintain the annual BFT quota specification process established in the 1999 FMP, which allocates the ICCAT-recommended U.S. BFT quota annually to domestic user groups. This alternative would require NMFS to draft proposed annual BFT quota specifications and appropriate supporting analytical documents, collect public comment on those proposed specifications, and then, after responding to comments received, finalize the initial BFT quota specifications via a final rule published in the Federal Register. This process would establish the baseline domestic quota category allocations in weight, as well as any applicable subquota allocations, and account for any under/overharvests from the previous fishing year.

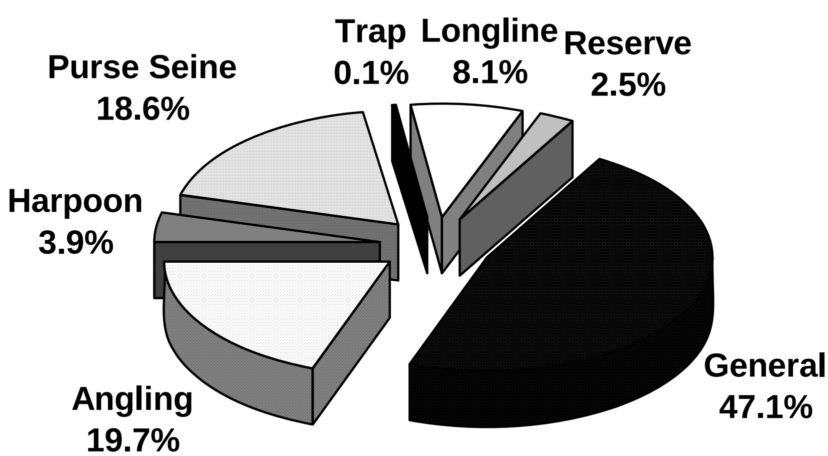

**Figure 2.14 Alternative F5: No Action. U.S. BFT Domestic Quota Category Allocation Percentages.**

This alternative would maintain and implement annual adjustment procedures, which include accounting for unused quota or an overage from the previous year, within individual domestic quota categories, via the current annual specification process. These annual adjustments would be based on landings statistics and other available information, and consideration of which BFT quota in any category or, as appropriate, subcategory has been exceeded or has not been reached, with the exception of the Purse seine category due to the IFQ nature of this category. Any overharvest would be subtracted from, or the underharvest would be added to, that same quota category for the following fishing year, provided that the total of the adjusted category quotas and the Reserve remained consistent with ICCAT recommendations, the tolerance of school BFT, and the allowance for dead discards. For the Purse seine category, annual adjustments would be based on landings statistics and other available information for that specific purse seine vessel's allocation. Adjustments would then be considered based on calculations of whether a purse seine vessel's allocation, as adjusted, has been exceeded or has not been reached, in which case the overharvest would be subtracted from, or underharvest would be added to, that vessel's allocation for the following fishing year. Under this alternative, there would be no limit on the amount of quota that could be carried forward from one year to the next in any domestic quota category.

This alternative would implement annual adjustment procedures to allocate any quota in the Reserve category at the end of a fishing year to account for overharvests in any fishing category, provided such allocation is consistent with the criteria specified in Section 2.3.1.3. This alternative would also maintain the authority to perform inseason actions within a fishing year, such as adjusting daily retention limits, quota transfers among categories or, as appropriate, subcategories, and performing interim closures. These inseason actions would be determined based on the consideration of the criteria stipulated in Section 2.3.1.3.

This alternative would maintain the default General and Angling category BFT retention limits as articulated in the regulations implementing the 1999 FMP. The default coast-wide General category BFT retention limit is one large medium or giant BFT, measuring 73 inches curved fork length (CFL) or greater, per vessel per day/per trip. The default Angling category BFT retention limit is one school, large school, or small medium BFT, measuring 27 inches to less than 73 inches CFL per vessel per day/trip. NMFS has the ability to change the default retention limits via an inseason action. For further details regarding inseason actions, please see Section 2.3.1.3.

Lastly, this alternative would maintain the procedure for establishing Restricted Fishing Days (RFDs) in the General category BFT fishery, by proposing them in the annual BFT quota specifications. An RFD means a day beginning at 0000 hours and ending 2400 hours local time, during which a person aboard a vessel for which a General category permit for Atlantic tunas has been issued may not fish for, possess, or retain BFT. RFDs are intended to extend the General category BFT season, reduce market gluts, and further achieve optimum yield. A designated RFD may be waived if it is determined that it would impede the attainment of a time-period subquota or an RFD may be introduced if it is determined that it is needed to avert a premature time-period closure. NMFS has the ability to alter the RFD schedule via an inseason action. For further details regarding inseason actions, please see Section 2.3.1.3.

Alternative F6 *Revise the annual BFT quota specification process to refer back to the supporting analytical documents of the consolidated HMS FMP and include seasonal management measures in annual framework actions – Preferred Alternative*

This alternative is similar to Alternative F5, in that BFT quota specifications would be conducted on an annual basis; however, the range of impacts associated with annual BFT specifications would be analyzed in the appropriate analytical documents of the consolidated HMS FMP, as opposed to a separate EA or EIS. The consolidated HMS FMP analyses would then be referred to and used in subsequent quota specifications as the supporting analytical documents for regulatory, environmental, social, and economic impact analyses. Analytical documents would accompany the annual BFT quota specifications only if the analyses associated with the consolidated HMS FMP no longer applied, (*i.e.*, if ICCAT were to amend its recommendation regarding the total U.S. BFT TAC). Currently, ICCAT recommendations for BFT TACs cover multiple years, and usually coincide with the most recent BFT stock assessment. The ICCAT-recommended U.S. BFT TAC would be allocated to the domestic quota categories per the allocation percentages listed in the consolidated HMS FMP (see introductory paragraph for Section 2.3.1.2). The equivalent quota tonnage associated with these percentages would be specified in the regulatory text implementing the consolidated HMS FMP, therefore formally establishing annual baseline quotas, in whole weight, for each of the domestic quota categories and therefore removing the need to analyze them on an annual basis as they would remain consistent.

The baseline quota percentages, for each domestic quota category, would remain in the consolidated HMS FMP, while the corresponding quota allocation for each quota category, denoted in metric tons, would be specified in the regulatory text implementing the consolidated HMS FMP. These baseline quota allocations may be adjusted on an annual basis to account for under/overharvests that occur in the previous year, per ICCAT recommendations. The range of these quota adjustments would also be analyzed in the supporting analytical documents of the consolidated HMS FMP and referred to in the annual BFT specifications (see Section 4.3.1.1, Alternative F8). This alternative would implement annual adjustment procedures that provide NMFS the authority to allocate any quota remaining in the Reserve category at the end of a fishing year to any fishing category, provided such allocation is consistent with the applicable determination criteria currently listed in the regulations. Section 2.3.1.3 addresses the multiple sets of determination criteria listed in the current regulations and the preferred alternative of this section which would consolidate the multiple lists for consistency purposes. As any annual quota transfers from the Reserve category are similar to an inseason quota transfer, the determination criteria discussed in Section 2.3.1.3 would also be addressed prior to conducting an annual transfer from the Reserve category.

This alternative would also include seasonal management measures in the annual framework rulemaking. Under the No Action alternative (*i.e.*, in comparison to Alternative F5), inseason management is conducted separately from the annual rulemaking. These seasonal management measures may include, but would not be limited to, establishing recreational daily BFT retention limits and their duration and General category effort controls, such as RFDs and daily BFT retention limits. Including seasonal management measures in the annual BFT specifications would provide prior notice of, and an opportunity for the public to comment on any proposed actions. Subsequent inseason actions would likely still be necessary to close fisheries, alter seasons, and/or alter retention limits as changing fishery conditions warrant them. This alternative would also maintain the inseason action authority as discussed under Section 2.3.1.3.

Alternative F7 Eliminate unharvested quota carryover provisions and return unharvested quota to the resource, while maintaining status quo overharvest provisions

This alternative would implement an annual adjustment provision that would not allow unharvested quota to be carried forward from one fishing year to the next, but would start each fishing year with the baseline domestic quota category allocations. This alternative would maintain the overharvest provision and annual adjustment procedures as described in Alternative F5.

Alternative F8 *Establish an individual quota category carryover limit of 100 percent of the baseline allocation (i.e., no more than the annual baseline allocation may be carried forward), except for the Reserve category, and authorize the transfer of quota exceeding the 100 percent limit to the Reserve or another domestic quota category, while maintaining status quo overharvest provisions – Preferred Alternative*

This alternative would implement similar carryover provisions described in Alternative F5, but may apply a limit to the amount of quota each domestic quota category could carry forward from one fishing year to the next. This limit may be applied to all domestic quota categories, except for the Reserve category. The intent of this alternative is to prevent "stockpiling" of unharvested quota in a particular domestic quota category due to multiple successive years of underharvest. This alternative would implement a carryover cap of 100 percent of the baseline allocation for each domestic quota category, except for the Reserve category, such that no more than two years worth of quota allocation may be held by a particular domestic quota category at the start of the fishing year. For example, the Harpoon category is allocated 3.9 percent of the U.S. BFT quota. Using the current ICCAT BFT quota recommendation, this equates to an annual baseline allocation of approximately 57.1 mt. Under this alternative, the Harpoon category would be allowed to carry forward 57.1 mt of unharvested quota from one year to the next. Combining the Harpoon category annual baseline allocation of 57.1 mt with the unharvested quota that may be carried forward, 57.1 mt, and the Harpoon category quota would be limited to 114.2 mt. Any quota that exceeds the 100 percent carryover limit would then be transferred to either the Reserve category or to another domestic quota category. This preferred alternative would not preclude NMFS from transferring additional quota from the Reserve back to a category that has reached the rollover limit via an inseason action. Section 2.3.1.3 addresses the multiple sets of determination criteria listed in the current regulations and the preferred alternative of this section which would consolidate multiple criteria lists for consistency purposes. As any quota transfers associated with exceeding the 100 percent rollover limit would be similar to an inseason quota transfer, the determination criteria discussed in Section 2.3.1.3 would also need to be addressed prior to transferring quota under this alternative. This alternative would maintain the overharvest provisions as stipulated in Alternative F5.

#### *2.3.1.3 Inseason Actions*

The following alternatives set forth the basis for NMFS' management of BFT inseason actions, including, but not limited to adjusting daily retention limits, inseason quota transfers, and fishery closures/reopenings.

Alternative F9 Maintain inseason action procedures (No Action)

This alternative would maintain and implement the status quo regulatory authority to provide for maximum utilization of the BFT quota by authorizing increases or decreases to the General category daily retention limit of large medium and giant BFT over a range from zero to a maximum of three per vessel via the use of inseason management actions that are published in the final rule section of the Federal Register. These actions would be based on a review of dealer reports, daily landing trends, availability of the species on the fishing grounds, and any other relevant factors. General category retention limit adjustments are not effective until at least three calendar days after a notification is filed with the Office of the Federal Register for publication. The one exception corresponds to previously designated RFDs. RFDs may be waived effective upon closure of the General category fishery so that persons aboard vessels permitted in the General category may conduct catch-and-release or tag-and-release fishing for BFT under § 635.26.

This alternative would maintain and implement the existing regulatory authority to provide for maximum utilization of the Angling category BFT quota, by authorizing adjustments that may increase or decrease the recreational retention limit for any size-class BFT or change a vessel trip limit to an angler limit and vice versa. Such adjustments would be based on a review of daily landing trends, availability of the species on the fishing grounds, and any other relevant factors. Also, such adjustments to the retention limits may apply separately for persons aboard a specific vessel type, such as private vessels, headboats, or charterboats. Recreational retention limit adjustments are not effective until at least three calendar days after a notification is filed with the Office of the Federal Register for publication.

This alternative would maintain and implement regulations that authorize quota transfers among categories or, as appropriate subcategories, within a fishing year after considering the following factors:

(A) The usefulness of information obtained from catches in the particular quota category for biological sampling and monitoring of the status of the stock;

(B) The catches of the particular category quota to date and the likelihood of closure of that segment of the fishery if no allocation is made;

(C) The projected ability of the vessels fishing under the particular category quota to harvest the additional amount of BFT before the end of the fishing year;

(D) The estimated amounts by which quotas for other gear categories of the fishery might be exceeded;

(E) Effects of the transfer on BFT rebuilding and overfishing;

(F) Effects of the transfer on accomplishing the objectives of the Fishery Management Plan for Atlantic Tunas, Swordfish, and Sharks.

If it was determined, based on these criteria and the probability of exceeding the total quota, that vessels fishing under any category or subcategory quota were not likely to take that quota, NMFS could conduct an inseason transfer of any portion of the remaining quota of that fishing category to any other fishing category or to the Reserve.

This alternative would maintain and implement regulations to close a domestic quota category, other than the Purse Seine category quota due to the IFQ nature of this category, based on when that quota was reached, or was projected to be reached. The closure would be effective for the remainder of the fishing year or for a specified period as indicated in the closure notice published as an inseason action in the final rule section of the Federal Register.

This alternative would also maintain and implement the regulations to close and reopen the Angling category BFT fishery by accounting for variations in seasonal distribution, abundance, or migration patterns of BFT, or catch rates in one area, which may have precluded anglers in another area from a reasonable opportunity to harvest a portion of the Angling category quota. The Angling category BFT fishery, or a part of the fishery, may be reopened at a later date if it is determined that BFT migrated into the other area. In determining the need for any such interim closure, the following criteria would be considered:

(A) The usefulness of information obtained from catches of a particular geographic area of the fishery for biological sampling and for monitoring the status of the stock;

(B) The current year catches from the particular geographic area relative to the catches recorded for that area during the preceding four years;

(C) The catches from the particular geographic area to date relative to the entire category and the likelihood of closure of that entire category of the fishery if no interim closure or area closure is effected; and

(D) The projected ability of the entire category to harvest the remaining amount of BFT before the anticipated end of the fishing season.

Alternative F10 *Revise and consolidate criteria considered prior to performing inseason and certain annual BFT management actions – Preferred Alternative*

This alternative would revise and consolidate the sets of criteria that NMFS considers for any and all inseason management actions, as well as certain annual management actions, including, but not limited to adjustments in daily retention limits, annual quota adjustments to/from the Reserve, inseason quota transfers, fishery closures, and interim fishery closure/reopenings. This alternative would enhance the flexibility and consistency regarding the determination criteria analyzed prior to conducting inseason management actions and/or some annual management actions as discussed in the previous alternatives. The criteria listed below are in no particular order of importance and in some circumstances not all criteria would be relevant in the decision making process.

This alternative would also move the determination criteria from § 635.27(a)(7) into a stand-alone section. Thus, this alternative would implement the following consolidated criteria:

(A) The usefulness of information obtained from catches in the particular category for biological sampling and monitoring of the status of the stock;

(B) The catches of the particular category quota, and/or subquota, to date and the likelihood of closure of that segment of the fishery if no interim closure or quota allocation is made;

(C) The projected ability of the vessels fishing under the particular category quota and/or subcategory quota to harvest the remaining and/or additional amount of BFT before the end of the fishing year;

(D) The estimated amounts by which quotas for other gear categories of the fishery might be exceeded;

(E) Effects of the action on BFT rebuilding and overfishing;

(F) Effects of the action on accomplishing the objectives of the consolidated HMS FMP;

(G) Review of variations in seasonal distribution, abundance, or migration patterns of BFT;

(H) Effects of catch rates in one area, precluding participants in another area from having a reasonable opportunity to harvest a portion of the category quota; and

(I) Review of dealer reports, daily landing trends, and/or availability of the species on the fishing grounds.

This alternative would maintain and implement regulations to close a domestic quota category, other than the Purse seine category quota due to the IFQ nature of this category, based on when that quota is reached, or is projected to be reached. The closure would be effective for the remainder of the fishing year or for a specified period as indicated in the closure notice published as an inseason action in the final rule section of the Federal Register.

Alternative F11 Eliminate BFT inseason actions

This alternative would eliminate NMFS' authority to perform inseason actions such as daily retention limit adjustments, inseason quota transfers, or interim closures. Domestic BFT quotas would be established as outlined in Section 0, and would be amended annually due to carryover provisions as outlined in Section 2.3.1.2. This alternative was designed to provide BFT fishery participants certainty in the rules and regulations throughout the BFT season for the purpose of consistency and at the expense of flexibility.

### 2.3.2 Timeframe for Annual Management of HMS Fisheries

Many aspects of HMS fisheries are managed on an annual cycle, including, but not limited to, quota distribution, permit issuance, and fishery specifications. Currently, sharks are managed on a calendar year cycle (January 1 to December 31) while tunas, swordfish, and billfish are managed on a fishing year cycle (June 1 to May 31). For example, the 2005 annual quotas recommended by ICCAT for the U.S. tuna and swordfish fisheries are implemented for the fishing year from June 1, 2005 to May 31, 2006, and the annual 2005 domestic shark fishery quotas are based on a fishing year from January 1, 2005 through December 31, 2005 (ICCAT does not currently make recommendations for annual shark quotas). The following alternatives present options for shifting the management cycle timeframe in order to simplify the management program for HMS fisheries and improve the United States' basis for negotiations at international forums.

Alternative G1 Maintain the current management cycle for all HMS (No Action)

This alternative would maintain the current management timeframe for all managed HMS. Atlantic tunas, swordfish, and billfish would continue to be managed on a fishing year from June 1 to May 31, whereas Atlantic sharks would continue to be managed on a calendar year. This alternative would not require any re-allocation of the sub-quotas used to manage BFT, sharks, or swordfish.

Alternative G2 *Shift the management cycle to January 1 to December 31 for all HMS – Preferred Alternative*

Under this alternative, the preferred alternative for the Draft HMS FMP, all of the HMS management programs would be implemented on a calendar year cycle. The Atlantic shark management timeframe would maintain the status quo, whereas tunas, swordfish, and billfish would shift from a fishing year to a calendar year. The calendar year for billfish would be implemented on January 1, 2007 via this action. To transition from a fishing year to a calendar year, an abbreviated fishing year would be established via a separate action for BFT and swordfish to cover the months between the end of the fishing year (May 31, 2007) and the start of the new calendar year (January 1, 2008). This alternative has been refined relative to the Draft HMS FMP by shifting the effective date for BFT and swordfish from January 1, 2007 to January 1, 2008. The shift in the management timeframe would require some alteration to the BFT seasonal allocations because a domestic BFT subquota and time-period currently spans two calendar years. Section 2.1.1.1 discusses management alternatives for BFT, including all the subalternatives under alternative F3, which would address this issue by providing separate subquota time periods for December and January.

Alternative G3 Shift the management cycle to June 1 to May 31 for all HMS

This alternative would move all HMS to a June 1 to May 31 fishing year management cycle. The management timeframe for Atlantic tunas, swordfish, and billfish would maintain status quo, whereas shark management would shift from the calendar year to a fishing year. The shark management program's trimesters and sub-quotas would be modified to fit within a fishing year management regime, and a bridge period would be required to cover the months between the end of the calendar year (December 31, 2006) and beginning of the fishing year (June 1, 2007).

### 2.3.3 Authorized Fishing Gear

Innovative fishing gears and techniques are essential to increasing efficiency and reducing bycatch in fisheries for Atlantic HMS. As current or traditional gears are modified and new gears are developed, NMFS needs to be cognizant of these advances to gauge their potential impacts on target catch rates, bycatch rates, and protected species interactions, all of which can have important management implications. New gears and techniques need to be evaluated by NMFS for qualification as authorized gear types. In this document, NMFS is considering the definition and authorization of speargun gear, green-stick gear, and buoy gear, as well as clarifying the allowable use of handheld cockpit gears.

Alternative H1 Maintain current authorized gears in Atlantic HMS fisheries (No Action)

The revised list of authorized fisheries (LOF) and the associated fishing gears became effective December 1, 1999 (64 FR 67511). The rule applies to all U.S. marine fisheries, including Atlantic HMS. As stated in the rule, "no person or vessel may employ fishing gear or participate in a fishery in the exclusive economic zone (EEZ) not included in this LOF without giving 90 days' advance notice to the appropriate Fishery Management Council (Council) or, with respect to Atlantic HMS, the Secretary of Commerce (Secretary)." The LOF is updated periodically and can be found at 50 CFR § 600.725. Acceptable HMS fisheries and authorized gear types for Atlantic tunas, swordfish, and sharks include: <u>swordfish handgear fishery</u> - rod and reel, harpoon, handline, bandit gear; <u>pelagic longline fishery</u> - longline; <u>shark drift gillnet fishery</u> - gillnet; <u>shark bottom longline fishery</u> - longline; <u>shark recreational fishery</u> - rod and reel, handline; <u>tuna purse seine fishery</u> - purse seine; <u>tuna recreational fishery</u> - rod and reel, handline; and <u>tuna handgear fishery</u> - rod and reel, harpoon, handline, bandit gear. For Atlantic billfish, the only acceptable fishery and authorized gear type is recreational fishery - rod and reel. This alternative would maintain the status quo for authorized gears in all Atlantic HMS fisheries.

Alternative H2 *Authorize speargun fishing gear as a permissible gear type in the recreational Atlantic BAYS tuna fishery - Preferred Alternative*

Alternative H2 would define and authorize speargun fishing gear in the recreational Atlantic bigeye, albacore, yellowfin and skipjack (BAYS) tuna fishery (*i.e.*, all regulated HMS tuna species except for BFT). This is a slightly modified alternative from that proposed in the Draft Consolidated HMS FMP. This preferred alternative modifies the proposed alternative contained in the Draft Consolidated HMS FMP by not allowing BFT to be fished for, landed, or retained by fishermen using speargun gear. In addition, this revised alternative would not allow the sale of any BAYS tuna harvested with speargun gear, under any circumstances, including those landed by fishermen aboard a HMS CHB permitted vessel and regardless of whether the CHB permitted vessel is operating in a for-hire or non-for-hire manner. BFT would be excluded from the allowed list of target species by this new gear type due to the recent declining performance of the existing BFT fishery, recent quota limited situations within the recreational angling sector, and ongoing concerns over the status of the stock. All sale of tuna harvested with this gear type would be prohibited in order to clarify the intent of authorizing this gear type, which would be to allow recreational speargun fishermen an opportunity to use speargun gear to recreationally target BAYS tuna. Recreational spearfishermen would only be allowed to fish from vessels possessing valid HMS Angling or CHB category permits, and would be subject to all Federal management measures for recreational HMS fishing including retention limits for YFT, a minimum size of 27 inches for BET and YFT, and reporting requirements, as well as other measures. Speargun landings would be monitored using existing recreational monitoring methods, including LPS. Under this alternative, no HMS would be allowed to be taken by speargun gear, other than Atlantic BAYS tunas.

Fishermen using speargun gear would be allowed to freedive, use SCUBA, or other underwater breathing devices, and would be required to be physically in the water when firing or discharging a speargun. Only free-swimming fish, not those restricted by fishing lines or other means, could be taken with a speargun.

Under alternative H2, speargun fishing gear would be defined as a muscle-powered speargun equipped with a trigger mechanism, a spear with a tip designed to penetrate and retain fish, and terminal gear. Terminal gear may include but would not be limited to trailing lines, reels, and floats. Muscle-powered spearguns store potential energy provided from the operator's muscles. Muscle-powered spearguns may only release that amount of energy that the operator has provided to it from his/her own muscles. Common energy storing methods for muscle-powered spearguns include compressing air and springs, and the stretching of rubber bands (IBSRC, 2005) (Figure 2.15). Powerheads, as defined at 50 CFR § 600.10, or any other explosive devices, would not be allowed to harvest or subdue BAYS tunas with this gear type.

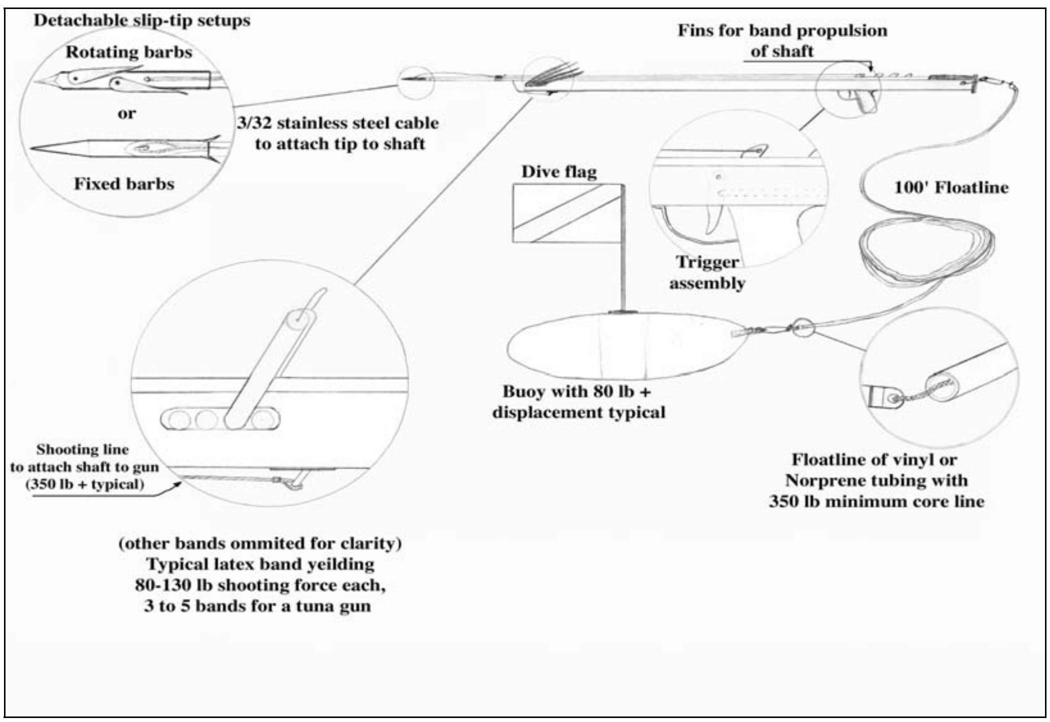

**Figure 2.15 A Diagram of a Typical Speargun Fishing Gear Configuration** (courtesy of Matthew Richards).

Alternative H3 Authorize speargun fishing gear as a permissible gear-type in the commercial tuna handgear and recreational Atlantic tuna fisheries

Alternative H3 would authorize the use of speargun fishing gear, as defined above, in the commercial tuna handgear and recreational Atlantic tunas fisheries. Recreational BFT speargun landings would be deducted from the Angling category quota and commercial BFT speargun landings would be subtracted from the General category quota. As discussed in alternative H2, fishermen using speargun fishing gear would be allowed to freedive, use SCUBA, or other underwater breathing devices, and would be required to be physically in the water when firing a speargun. Only free-swimming fish, not those restricted by fishing lines or any other devices, could be taken. The use of powerheads, as defined at 50 CFR § 600.10, or any other explosive devices, would not be allowed to harvest or subdue tunas with this gear type. Under this alternative, no HMS would be allowed to be taken by speargun gear, other than Atlantic tunas.

Alternative H4 Authorize green-stick fishing gear for the commercial harvest of Atlantic BAYS tunas

Alternative H4 would add a definition of green-stick fishing gear to the Atlantic HMS regulations and add this gear to the list of authorized fishing gears for the commercial tuna handgear fishery for certain fishing permits. This alternative was preferred in the Draft Consolidated HMS FMP, however it is not preferred in the Final Consolidated HMS FMP. Under this alternative, green-stick gear would be distinguished from current definitions of existing gear types and individually defined as a line that is elevated, or suspended, above the waters' surface from which no more than 10 hooks or gangions may be hung. Possible technical configuration and use of the gear would be similar to that described below. The intent of this alternative would be to allow commercial tuna handgear fishermen, targeting BAYS with green-stick gear, to increase the number of hooks on their gear from two hooks to no more than 10 hooks. This alternative would also prohibit commercial vessels using or possessing green-stick fishing gear from retaining or possessing BFT on board. The primary impacted commercial fishing entities would be General category and HMS CHB permit holders, who are currently restricted to the handgear limit of two hooks or less per line, but are allowed to sell their BAYS catch, in accordance with other appropriate management measures (*e.g.*, size limits). Longline permit holders are currently allowed to use three hooks or more per line although they are restricted to the use of circle hooks only, among other restrictions (*e.g.*, closed areas). This alternative would not impact HMS recreational fishermen targeting BAYS as they are already not allowed to sell their catch.

During the public comment period for the Draft Consolidated HMS FMP, commenters provided a range of opposition and support regarding this previously preferred alternative (to authorize green-stick gear for the commercial harvest of Atlantic BAYS tunas) including; considerable confusion over the current regulatory regime; concern over the need for better reporting, monitoring and overall data collection for this gear-type; and, the need for further understanding of the technical nature of the gear itself. Based on these comments, the Agency has determined it would be preferable to clarify the currently allowed use of the green-stick gear rather than proceed with authorization and definition of the gear-type in a manner that may further add to the confusion and have unintended negative consequences to the fishery and the resource.

Below is a brief discussion of the currently allowed and authorized use of green-stick gear in HMS fisheries. The gear is currently recognized to be configured in at least two different modes classified as "recreational" and "commercial." In either mode, the gear is actively trolled and configured so that the baits are fished on or above the surface of the water. The suspended line, attached gangions, and catch may be retrieved collectively by hand or mechanical means. The discussion below is solely intended to further understanding of the technical nature and possible use of this gear. Despite the terminology of these modes, it is possible for the actual use of the gear, in either mode, to exist in the commercial or the recreational HMS fisheries in accordance with existing HMS and tuna permit requirements and HMS management measures.

In the “recreational” configuration, a fiberglass pole, or “green-stick”, serves as a vertical outrigger, elevating a line above the waters’ surface, allowing multiple anglers to fish individually tended lines suspended by the green-stick’s single line (Figure 2.16). At the end of the green-stick line, a floating decoy is attached. This decoy provides drag as the vessel moves forward and puts tension on the green-stick line. The individual fishing lines are connected to the green-stick line by rubber bands, outrigger clips, or other breakaway connections, and are allowed to hang down and brush across the surface of the water while trolled. When a fish takes one of the baits, the breakaway connection releases, and the angler tending that individual line fights and lands the fish. Some recreational fishermen have further modified the gear and suspend baits from a “high-line” attached to a flying bridge or tuna tower, and do not actually use the green-stick pole (Wescott, 1996).

It is believed that this “recreational” configuration is primarily used to target YFT, although BFT, other BAYS species, and possibly billfish can be captured via this method. So long as each separate and individual fishing line that is attached to the mainline <u>only trails two hooks or fewer</u> this configuration would fall under current HMS regulatory handgear definitions for rod and reel and handline. Rod and reel and handline gears are already authorized for either recreational or commercial fishing for HMS species under existing regulations. Fishermen wishing to use green-stick gear in this manner would need to possess any of the HMS permits that authorize the use of rod and reel or handline, including HMS CHB, HMS Angling, Atlantic tunas General category permits, or Swordfish and Shark limited access permits. Again, it is important to note that although the configuration may be termed “recreational,” HMS species landed under the HMS commercial permits (authorized for handgear) and using this configuration (*e.g.,* all except the HMS Angling permit) may be sold as normal, under existing regulations.

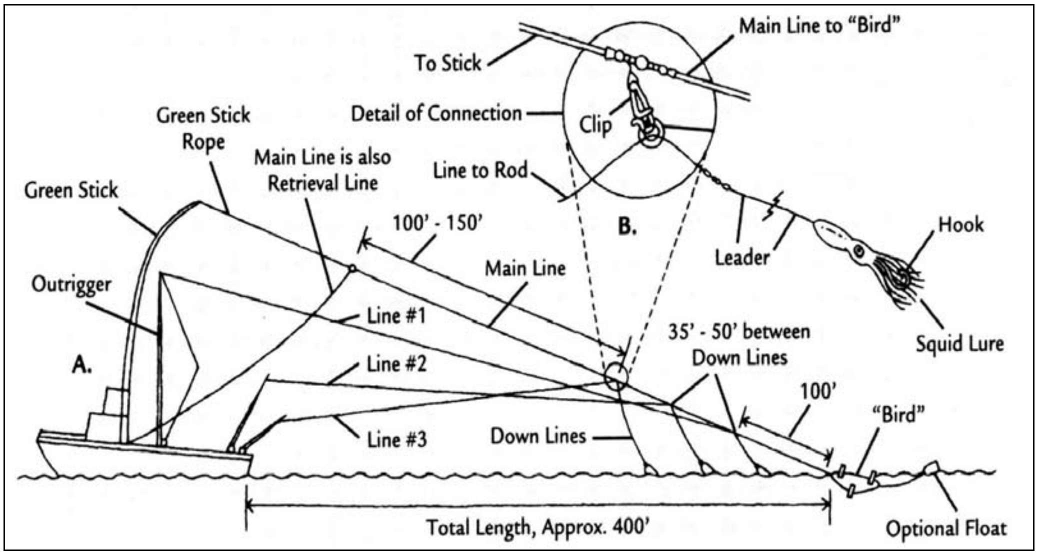

**Figure 2.16 A Diagram of the Recreational Configuration of Green-stick Fishing Gear.** Source: Wescott, 1996

The "commercial" configuration of green-stick gear generally consists of a 10.7 - 13.7 m (35 - 45 feet) fiberglass pole mounted to the vessel. A heavy mainline (800-1,000-pound test line) housed in a spool is hoisted by a tether-rope mounted to the top of the pole. The mainline is connected to the tether-rope with a cotton breakaway cord. At the end of the mainline, a floating decoy is attached. This decoy provides drag as the vessel moves forward and puts tension on the mainline. Several leaders hang down from the mainline at regularly spaced intervals and suspend baits so that they brush across the top of the water (Figure 2.17). As this gear is towed, the baits attached to the mainline skip across the water's surface and flex in the fiberglass pole produces a "jigging" action that attracts fish. This gear was designed so that the mainline breaks away from the tether rope when one or more fish are hooked. The mainline and all the fish are then retrieved together using the spool (Wescott, 1996).

It was understood that the "commercial" configuration of green-stick gear was primarily used on vessels targeting YFT. However, since publication of the Draft Consolidated HMS FMP, public comments to the Agency, particularly from the North Carolina area, have made it clear that there is interest and potential activity targeting other species, including BFT. Theoretically, it is possible to use this "commercial" mode of configuration with a main line that only trails two hooks or less. In this case, it would also fall under current HMS regulatory handgear definitions for rod and reel and handline and is thus already authorized for either commercial or recreational fishing for HMS species under existing regulations. However, when fishing in this mode, it is likely that more than two hooks would be applied to the line. In cases where <u>more than two hooks</u> are attached to the mainline, the use of this gear would fall under the current HMS regulatory definition for longline gear. Fishermen wishing to use the commercial configuration with more than two hooks could still use this configuration of green-stick gear but would need to hold an Atlantic tunas longline permit and other necessary limited access permits depending on species and amounts targeted. An important note to consider under these circumstances is the relatively recent regulatory requirement (69 FR 40734, July 6, 2004) that vessels using pelagic longline gear are limited at all times to possessing on board and using only circle hooks (50 CFR 635.21).

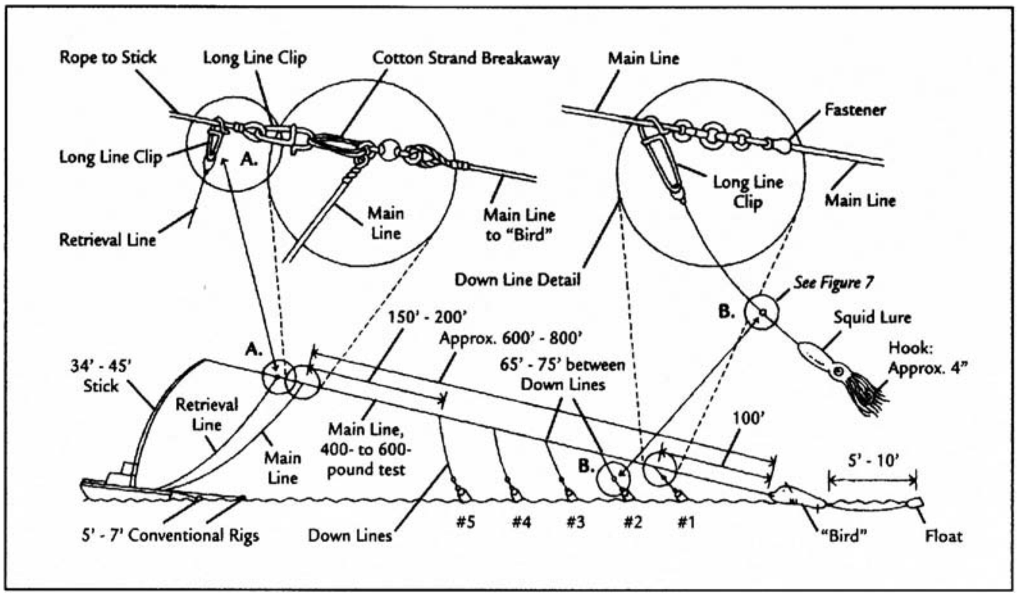

**Figure 2.17 A Diagram of the Commercial Configuration of Green-stick Fishing Gear.** Source: Wescott, 1996

Although the alternative to explicitly define and authorize green-stick gear is not preferred in the Final Consolidated HMS FMP, fishermen are still allowed to use green-stick gear as a form of currently approved handgear or longline gear. Under current HMS regulations, either configuration described above is already authorized, provided vessels are issued a valid HMS vessel permit and abide by all gear operation and deployment restrictions (*e.g.*, number and type of hooks per line, closed areas), and management measures (*e.g.*, size and catch limits, target catch restrictions) appropriate for that HMS vessel permit.

Alternative H5 *Authorize buoy gear as a permissible gear type in the commercial swordfish handgear fishery; limit vessels employing buoy gear to possessing and deploying no more than 35 floatation devices, with each individual gear having no more than two hooks or gangions attached – Preferred Alternative*

Alternative H5 would define and authorize buoy gear in the commercial swordfish handgear fishery. This alternative has been modified from the alternative proposed in the Draft Consolidated HMS FMP to allow the use of more than one floatation device per buoy gear. This modification was made in response to public comment. Additional detail regarding this change can be found in Chapter 4. The swordfish handgear fishery may currently utilize individual handlines attached to free-floating buoys; however, another preferred alternative in this document (I5(b)) would require that handlines used in HMS fisheries be attached to a vessel. Alternative H5 would change the definition of individual free-floating buoyed lines, that are currently considered to be handlines, to "buoy gear," allowing the commercial swordfish handgear fishery to continue utilizing this gear type. This fishery has been operating under the current regulations, which require that handlines be restricted to no more than two hooks and be released and retrieved by hand. The current regulations do not limit the number of individual handlines/buoy gears that may be possessed or deployed and do not require that the lines be attached to a vessel. This gear (free-floating handlines) has been utilized with no limits on the number of gears by both recreational and commercial fishermen in many areas, including areas closed to pelagic longline fishing. Under alternative H5, only commercial swordfish fishermen possessing valid swordfish handgear or swordfish directed limited access permits would be authorized to utilize buoy gear and could only retain swordfish captured on this gear. Alternative H5 would maintain current limits of no more than two hooks per buoy gear and requirements that the gear be released and retrieved by hand; however, it would limit the number of individual floatation devices possessed or deployed to no more than 35 per vessel.

There is an existing definition of buoy gear at 50 CFR § 600.10 which states that "buoy gear means fishing gear consisting of a float and one or more lines suspended therefrom. A hook or hooks are on the lines at or near the end. The float and line(s) drift freely and are retrieved periodically to remove catch and rebait hooks." The proposed HMS definition of buoy gear is consistent with this general definition; however, the Agency would provide a more specific definition for the use of buoy gear in the commercial swordfish handgear fishery. NMFS feels it is appropriate to include a refined definition of buoy gear at 50 CFR § 635 given the nature and characteristics of the swordfish fishery, as well as gear and techniques commonly utilized.

Under alternative H5, buoy gear would be defined as a fishing gear consisting of one or more floatation devices supporting a single mainline to which no more than two hooks or gangions are attached. Fishermen using buoy gear would be required to mark each floatation device with the vessel's name, registration number, or HMS permit number, as per current regulations at 50 CFR § 635.6 (c). Under alternative H5, buoy gear would be required to be constructed and deployed so that the hooks would be attached to the vertical portion of the mainline. Floatation devices could be attached to one, but not both ends of the mainline, and no hooks or gangions could be attached to any floatation device or horizontal portion of the mainline. If more than one floatation device were attached to a buoy gear, no hook or gangion may be attached to the mainline between them (Figure 2.18). Individual buoy gears could not be connected together in any way and all buoy gears would be required to be released and retrieved by hand. Under this alternative, fishermen using this gear type would be required to affix gear monitoring equipment to each individual buoy gear to aid in recovery. Gear monitoring equipment could include, but would not be limited to, radar reflectors, beeper devices, lights, or reflective tape. If only reflective tape were used, the vessel deploying the buoy gear would be required to possess an operable spotlight capable of illuminating deployed buoys. If a gear monitoring device were positively buoyant and rigged to be attached to a fishing gear, it would be included in the 35 floatation device vessel limit and would need to be marked appropriately. Additionally, a floatation device would be defined as any positively buoyant object rigged to be attached to a fishing gear.

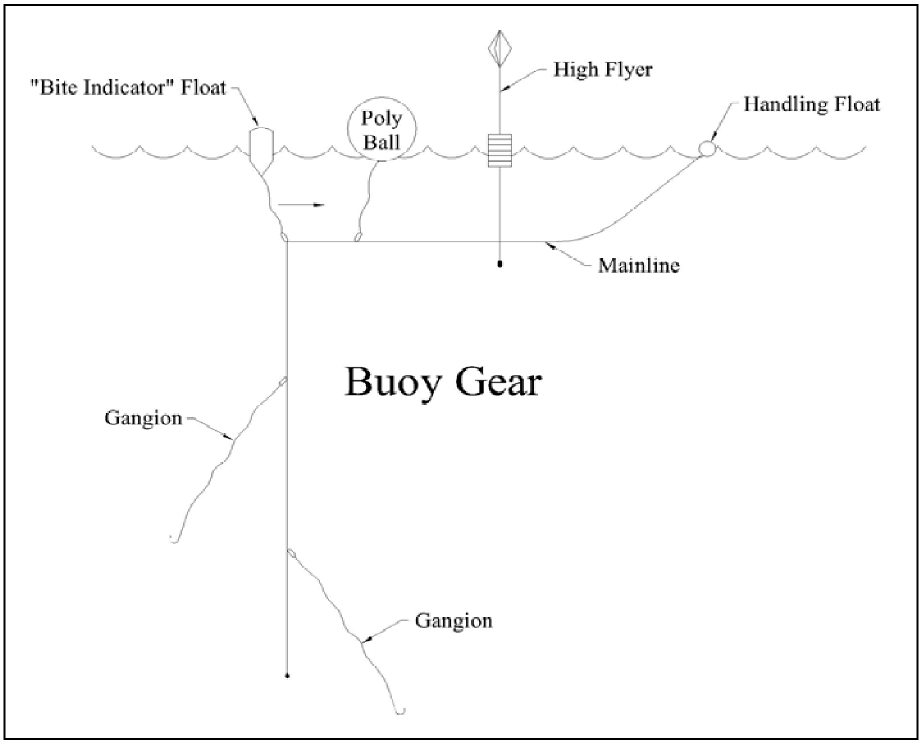

**Figure 2.18 A Diagram of a Buoy Gear with Four Floatation Devices Attached** (courtesy of Dave Meyer).

Alternative H6 Authorize buoy gear as a permissible gear type in the commercial swordfish handgear fishery; limit vessels employing buoy gear to possessing and deploying no more than 50 floatation devices, with each individual gear having no more than 15 hooks or gangions attached

Alternative H6 would authorize the use of buoy gear, as defined above, in the commercial swordfish handgear fishery. This alternative is similar to H5; however, it would limit vessels to possessing and deploying no more than 50 floatation devices, with each buoy gear having no more than 15 hooks or gangions attached. This alternative has been modified from the alternative proposed in the Draft Consolidated HMS FMP to allow the use of more than one floatation device per buoy gear. This modification was made to provide an appropriate comparison to alternative H5 which was modified in response to public comment. Additional detail regarding this change can be found in Chapter 4

Alternative H7 *Clarify the allowance of hand-held cockpit gears used at boat side for subduing HMS captured on authorized gears - Preferred Alternative*

In recent years, NMFS has become aware of some confusion regarding the allowable use of hand-held cockpit gears. Constituents have stated that they are unsure of whether they are allowed to possess cockpit gears, such as gaffs and dart harpoons, onboard their vessels if these gears are not specifically authorized in their particular fishery or permit category. This confusion stems from the Atlantic HMS regulations regarding authorized gears located at 50 CFR § 635.21(e). In this section, NMFS lists the authorized primary gear types that Atlantic HMS permit holders are allowed to use. The gear types are based on the species being targeted and the permit category of the particular vessel. It is NMFS' intent to only authorize the primary gear types used to harvest HMS, meaning the gears used to bring an HMS to the vessel. This issue is being addressed to clarify the allowable use of secondary gears to subdue HMS after they are brought to the vessel using a primary gear type.

Alternative H7 would clarify the allowance of secondary hand-held cockpit gears by amending existing text at 50 CFR § 635.21 (b). The text would state that:

> No person may fish for, catch, possess, or retain any Atlantic HMS other than with the primary authorized gears, which are the gears specifically authorized in this part. Consistent with paragraphs (a)(1) and (a)(2) of this section, secondary gears may be used to aid and assist in subduing, or bringing on board a vessel, Atlantic HMS that have first been caught or captured using primary gears. For purposes of this part, secondary gears include, but are not limited to, dart harpoons, gaffs, flying gaffs, tail ropes, etc. Secondary gears may not be used to capture, or attempt to capture, free-swimming or undersized HMS.

This alternative would acknowledge and account for the current regulations located at 50 CFR § 635.21(a), which state that an Atlantic HMS harvested from its management unit that is not retained must be released in a manner that will ensure maximum probability of survival, but without removing the fish from the water. Under this alternative, cockpit gears would not be allowed to be used in any way to capture, or attempt to capture, free-swimming or undersized HMS, but only to gain control of legal-sized HMS brought to the vessel via an authorized primary gear type, with the intent of retaining that HMS.

### 2.3.4 Regulatory Housekeeping

This section addresses several items in the HMS regulations that need to be "cleaned up," including minor corrections, clarifications, the removal or modification of obsolete cross-references, and minor changes to definitions and prohibitions that will improve the administration and enforcement of HMS regulations. Several of these items have been identified by constituents over the past few years or were raised during scoping hearings. Most of the corrections, clarifications, changes in definitions, and modifications to remove obsolete cross-references are consistent with the intent of previously analyzed and approved management measures. These changes would have no effect either individually or cumulatively upon the human environment. Under NOAA Administrative Order 216-6, actions that modify previously analyzed actions and that do not affect the human environment, minor technical additions, corrections, or changes to existing regulations are categorically excluded from the requirements of an EA or EIS. Changes that meet these criteria, and that are therefore exempt from the NEPA requirements, are described in Section 2.3.4.1 with the current regulation in the left column and the amendment in the right column. Other, more substantive, changes for which alternatives have been analyzed pursuant to NEPA, the Regulatory Flexibility Act, or other applicable laws are discussed in Section 2.3.4.2.

### 2.3.4.1 *Proposed Regulatory Changes That Do Not Need Alternatives*

Table 2.2 presents a list of the current regulations and the amendments to those regulations that will be effective in the final rule. The actual changes in the final rule may differ slightly from what is presented here due to overlap between these changes and changes due to other preferred actions in this document. However, the final rule will reflect the intent for the change, as described in the last column of the table.

**Table 2.2 List of Proposed Regulatory Changes.**

| Item Number | Current Regulation | Amendment | Rationale for Amendment |
|---|---|---|---|
| 1 | **§ 635.2 Definitions.**<br><br>*ILAP* means an initial limited access permit issued pursuant to §635.4. | **§ 635.2 Definitions.**<br><br>Remove the definition for ILAP. | Removes the definition of Initial Limited Access Permits (ILAPs), which are no longer issued. |
| 2 | **§ 635.2 Definitions.**<br><br>*Management unit* means in this part: * * * (5) For sharks, means all fish of these species in the western north Atlantic Ocean, including the Gulf of Mexico and the Caribbean Sea, excluding those species listed in Table 2 of Appendix A. | **§ 635.2 Definitions**<br><br>*Management unit* means in this part: * * * (5) For sharks, means all fish of the species listed in Table 1 of Appendix A to this part, in the western north Atlantic Ocean, including the Gulf of Mexico and the Caribbean Sea. | Specifies the species that are part of the management unit, rather than those that are not part of the management unit. |
| 3 | **§ 635.2 Definitions.**<br><br>*Northeast Distant closed area* *** * *** | **§ 635.2 Definitions.**<br><br>*Northeast Distant gear restricted area* *** * *** | Amends title of the Northeast Distant closed area to reflect recent amendments to the regulations governing this area. The term is also replaced throughout the regulations. |
| 4 | **§ 635.2 Definitions.**<br><br>*Shark* means one of the oceanic species, or a part thereof, listed in tables 1 and 2 in Appendix A to this part. | **§ 635.2 Definitions.**<br><br>*Shark* means one of the oceanic species, or a part thereof, listed in Table 1 in Appendix A to this part. | Links the definition of "shark" to the definition of "management unit." |
| 5 | **Table 2 in Appendix A - List of Deepwater and other sharks** | Revise **Table 2 in Appendix A by replacing it with another non-related table**.<br><br>NOTE – Table 2 is revised pursuant to measures described in Issue 1 in "Regulatory Housekeeping." | Removes the table of deepwater and other shark species that were previously removed from the management unit. NMFS will continue to collect data on these species and may add them to the management unit in the future. |

| Item Number | Current Regulation | Amendment | Rationale for Amendment |
|---|---|---|---|
| **6** | **§ 635.4(c)(2)** A vessel issued an Atlantic Tunas General category permit under paragraph (d) of this section may fish in a recreational HMS fishing tournament if the vessel has registered for, paid an entry fee to, and is fishing under the rules of a tournament that has notified NMFS as required under § 635.5(d). When a vessel issued an Atlantic Tunas General category permit is fishing in such a tournament, such vessel must comply with HMS Angling category regulations, except as provided in 635.4(c)(3). | **§ 635.4(c)(2)** A vessel issued an Atlantic Tunas General category permit under paragraph (d) of this section may fish in a recreational HMS fishing tournament if the vessel has registered for, paid an entry fee to, and is fishing under the rules of a tournament that has registered with NMFS as required under § 635.5(d). When a vessel issued an Atlantic Tunas General category permit is fishing in such a tournament, such vessel must comply with HMS Angling category regulations, except as provided in 635.4(c)(3). | Clarifies the requirement that tournaments must be registered with NMFS, consistent with proposed revisions to § 635.5(d). |
| **7** | **§ 635.4(d)(4)** A person can obtain an Atlantic Tunas Longline category permit for a vessel only if the vessel has been issued both a limited access permit for shark and a limited access permit for swordfish. NMFS will issue Atlantic Tunas Longline category permits to qualifying vessels in calendar year 1999. Thereafter, such permits may be obtained through transfer from current owners consistent with the provisions under paragraph (l)(2) of this section. | **§ 635.4(d)(4)** A person can obtain an Atlantic Tunas Longline category permit for a vessel only if the vessel has been issued both a limited access permit for shark and a limited access permit other than handgear for swordfish. Limited access Atlantic Tunas Longline category permits may only be obtained through transfer from current owners consistent with the provisions under paragraph (l)(2) of this section. | Removes a reference to a date that has passed. Also, clarifies that handgear permit holders cannot have an Atlantic Tunas Longline category permit because they cannot use longline gear to catch swordfish. |
| **8** | **§ 635.4(e)(1)** As of July 1, 1999, the only valid Federal commercial vessel permits for sharks are those that have been issued under the limited access criteria specified in §635.16. | **§ 635.4(e)(1)** The only valid Federal commercial vessel permits for sharks are those that have been issued under the limited access program consistent with the provisions under paragraphs (l) and (m) of this section. | Removes a date that has passed, and a cross-reference that has been removed. |

| Item Number | Current Regulation | Amendment | Rationale for Amendment |
|---|---|---|---|
| **9** | **§ 635.4(e)(2)** The owner of each vessel used to fish for or take Atlantic sharks or on which Atlantic sharks are retained, possessed with an intention to sell, or sold must obtain, in addition to any other required permits, only one of two types of commercial limited access shark permits: Shark directed limited access permit or shark incidental limited access permit. See §635.16 regarding the initial issuance of these two types of permits. It is a rebuttable presumption that the owner or operator of a vessel on which sharks are possessed in excess of the recreational retention limits intends to sell the sharks. | **§ 635.4(e)(2)** The owner of each vessel used to fish for or take Atlantic sharks or on which Atlantic sharks are retained, possessed with an intention to sell, or sold must obtain, in addition to any other required permits, only one of two types of commercial limited access shark permits: Shark directed limited access permit or shark incidental limited access permit. It is a rebuttable presumption that the owner or operator of a vessel on which sharks are possessed in excess of the recreational retention limits intends to sell the sharks. | Removes a cross-reference that has been removed. |
| **10** | **§ 635.4(f)(1)** The owner of each vessel used to fish for or take Atlantic swordfish or on which Atlantic swordfish are retained, possessed with an intention to sell, or sold must obtain, in addition to any other required permits, only one of three types of commercial limited access swordfish permits: swordfish directed limited access permit, swordfish incidental limited access permit, or swordfish handgear limited access permit. See §635.16 regarding the initial issuance of these three types of permits. | **§ 635.4(f)(1)** The owner of each vessel used to fish for or take Atlantic swordfish or on which Atlantic swordfish are retained, possessed with an intention to sell, or sold must obtain, in addition to any other required permits, only one of three types of commercial limited access swordfish permits: swordfish directed limited access permit, swordfish incidental limited access permit, or swordfish handgear limited access permit. It is a rebuttable presumption that the owner or operator of a vessel on which swordfish are possessed in excess of the recreational retention limits intends to sell the swordfish. | Removes a cross-reference that has been previously removed. Also, adds rebuttable presumption that swordfish possessed in excess of recreational retention limits are intended to be sold. |
| **11** | **§ 635.4(f)(2)** As of July 1, 1999, the only valid Federal vessel permits for swordfish are those that have been issued under the limited access criteria specified in §635.16. | **§ 635.4(f)(2)** The only valid Federal vessel permits for swordfish are those that have been issued under the limited access program consistent with the provisions under paragraphs (l) and (m) of this section.. | Removes a date that has passed, and a cross-reference that has been previously removed. |

| Item Number | Current Regulation | Amendment | Rationale for Amendment |
|---|---|---|---|
| 12 | **§ 635.4(h)(2)** *Limited access permits for swordfish and shark*. See §635.16 for the issuance of ILAPs for shark and swordfish. See paragraph (l) of this section for transfers of ILAPs and LAPs for shark and swordfish. See paragraph (m) of this section for renewals of LAPs for shark and swordfish. | **§ 635.4(h)(2)** *Limited access permits for swordfish and shark*. See paragraph (l) of this section for transfers of LAPs for shark and swordfish. See paragraph (m) of this section for renewals of LAPs for shark and swordfish. | Removes references to Initial Limited Access Permits (ILAPs), which are no longer issued. Also, removes a cross-reference that has been previously removed. |
| 13 | **§ 635.4(l)(2)(i)** Subject to the restrictions on upgrading the harvesting capacity of permitted vessels in paragraph (l)(2)(ii) of this section and to the limitations on ownership of permitted vessels in paragraph (l)(2)(iii) of this section, an owner may transfer a shark or swordfish ILAP or LAP or an Atlantic Tunas Longline category permit to another vessel that he or she owns or to another person. Directed handgear ILAPs and LAPs for swordfish may be transferred to another vessel but only for use with handgear and subject to the upgrading restrictions in paragraph (l)(2)(ii) of this section and the limitations on ownership of permitted vessels in paragraph (l)(2)(iii) of this section. Incidental catch ILAPs and LAPs are not subject to the requirements specified in paragraphs (l)(2)(ii) and (l)(2)(iii) of this section. | **§ 635.4(l)(2)(i)** Subject to the restrictions on upgrading the harvesting capacity of permitted vessels in paragraph (l)(2)(ii) of this section and to the limitations on ownership of permitted vessels in paragraph (l)(2)(iii) of this section, an owner may transfer a shark or swordfish LAP or an Atlantic Tunas Longline category permit to another vessel that he or she owns or to another person. Directed handgear LAPs for swordfish may be transferred to another vessel but only for use with handgear and subject to the upgrading restrictions in paragraph (l)(2)(ii) of this section and the limitations on ownership of permitted vessels in paragraph (l)(2)(iii) of this section. Incidental catch LAPs are not subject to the requirements specified in paragraphs (l)(2)(ii) and (l)(2)(iii) of this section. | Removes references to Initial Limited Access Permits (ILAPs), which are no longer issued. |

| Item Number | Current Regulation | Amendment | Rationale for Amendment |
|---|---|---|---|
| **14** | **§ 635.4(l)(2)(ii)(B)** The vessel's horsepower may be increased only once subsequent to the issuance of a limited access permit, whether through refitting, replacement, or transfer. Such an increase may not exceed 20 percent of the horsepower of the vessel's baseline specifications, as applicable. | **§ 635.4(l)(2)(ii)(B)** Subsequent to the issuance of a limited access permit, the vessel's horsepower may be increased only once, relative to the baseline specifications of the vessel originally issued the LAP, whether through refitting, replacement, or transfer. Such an increase may not exceed 20 percent of the baseline specifications of the vessel originally issued the LAP. | Clarifies that the one allowable horsepower upgrade for vessels with limited access permits is relative to the baseline specifications of the vessel originally issued the LAP. |
| **15** | **§ 635.4(l)(2)(ii)(C)** The vessel's length overall, gross registered tonnage, and net tonnage may be increased only once subsequent to the issuance of a limited access permit, whether through refitting, replacement, or transfer. Any increase in any of these three specifications of vessel size may not exceed 10 percent of the vessel's baseline specifications, as applicable. *** | **§ 635.4(l)(2)(ii)(C) )** Subsequent to the issuance of a limited access permit, the vessel's length overall, gross registered tonnage, and net tonnage may be increased only once, relative to the baseline specifications of the vessel originally issued the LAP, whether through refitting, replacement, or transfer. Any increase in any of these three specifications of vessel size may not exceed 10 percent of the baseline specifications of the vessel originally issued the LAP. * * * | Clarifies that the one allowable vessel size upgrade for vessels with limited access permits is relative to the baseline specifications of the vessel originally issued the LAP. |
| **16** | **§ 635.4(l)(2)(viii)** As specified in paragraph (f)(4) of this section, a directed or incidental ILAP or LAP for swordfish, a directed or an incidental catch ILAP or LAP for shark, and an Atlantic Tunas commercial category permit are required to retain swordfish. Accordingly, a LAP for swordfish obtained by transfer without either a directed or incidental catch shark LAP or an Atlantic tunas commercial category permit will not entitle an owner or operator to use a vessel to fish in the swordfish fishery. | **§ 635.4(l)(2)(viii)** As specified in paragraph (f)(4) of this section, a directed or incidental LAP for swordfish, a directed or an incidental catch LAP for shark, and an Atlantic Tunas longline category permit are required to retain swordfish. Accordingly, a LAP for swordfish obtained by transfer without either a directed or incidental catch shark LAP or an Atlantic Tunas longline category permit will not entitle an owner or operator to use a vessel to fish in the swordfish fishery. | Removes references to Initial Limited Access Permits (ILAPs), which are no longer issued. Changes general term "commercial" to "longline" to be consistent with the cross-reference to paragraph (f)(4). |

| Item Number | Current Regulation | Amendment | Rationale for Amendment |
|---|---|---|---|
| 17 | **§ 635.4(l)(2)(ix)** As specified in paragraph (d)(4) of this section, a directed or incidental ILAP or LAP for swordfish, a directed or an incidental catch ILAP or LAP for shark, and an Atlantic Tunas Longline category permit are required to retain Atlantic tunas taken by pelagic longline gear. Accordingly, an Atlantic Tunas Longline category permit obtained by transfer without either a directed or incidental catch swordfish or shark LAP will not entitle an owner or operator to use the permitted vessel to fish in the Atlantic tunas fishery with pelagic longline gear. | **§ 635.4(l)(2)(ix)** As specified in paragraph (d)(4) of this section, a directed or incidental LAP for swordfish, a directed or an incidental catch LAP for shark, and an Atlantic Tunas Longline category permit are required to retain Atlantic tunas taken by pelagic longline gear. Accordingly, an Atlantic Tunas Longline category permit obtained by transfer without either a directed or incidental catch swordfish or shark LAP will not entitle an owner or operator to use the permitted vessel to fish in the Atlantic tunas fishery with pelagic longline gear. | Removes references to Initial Limited Access Permits (ILAPs), which are no longer issued. |
| 18 | **§ 635.4(m)(2***) Shark, swordfish, and tuna longline LAPs*. As of June 1, 2000, the owner of a vessel of the United States that fishes for, possesses, lands or sells shark or swordfish from the management unit, or takes or possesses such shark or swordfish as incidental catch or that fishes for Atlantic tunas with longline gear must have the applicable limited access permit(s) issued pursuant to the requirements in §635.4, paragraphs (e) and (f). However, any ILAP that expires on June 30, 2000, is valid through that date. Only valid limited access permit holders in the preceding year are eligible for renewal of a limited access permit(s). Limited access permits that have been transferred according to the procedures of paragraph (l) of this section are not eligible for renewal by the transferor. | **§ 635.4(m)(2***) Shark, swordfish, and tuna longline LAPs*. The owner of a vessel of the United States that fishes for, possesses, lands or sells shark or swordfish from the management unit, or takes or possesses such shark or swordfish as incidental catch or that fishes for Atlantic tunas with longline gear must have the applicable limited access permit(s) issued pursuant to the requirements in paragraphs (e) and (f) of this section. Only persons holding a non-expired limited access permit(s) in the preceding year are eligible for renewal of a limited access permit(s). Limited access permits that have been transferred according to the procedures of paragraph (l) of this section are not eligible for renewal by the transferor. | Removes a date that has passed, and references to Initial Limited Access Permits (ILAPs), which are no longer issued. Also, replaces the word "valid" with "non-expired" to better clarify the intent of the paragraph. |

| Item Number | Current Regulation | Amendment | Rationale for Amendment |
|---|---|---|---|
| **19** | **§ 635.5(a)(4)** *Pelagic longline sea turtle reporting*. The operators of vessels that have pelagic longline gear on board and that have been issued, or are required to have, a limited access swordfish, shark, and tuna longline category permit for use in the Atlantic Ocean including the Caribbean Sea and the Gulf of Mexico are required to report any sea turtles that are dead when they are captured or that die during capture to the NOAA Fisheries Southeast Fisheries Science Center Observer Program, at a number designated by NOAA Fisheries, within 48 hours of returning to port, in addition to submitting all other reporting forms required by this part and 50 CFR parts 223 and 224. | Remove **§ 635.5(a)(4),** and redesignate subsequent sections as needed. | Removes a duplicative reporting requirement. Captured sea turtles would still be required to be reported in PLL logbooks, so no information is lost. |

| Item Number | Current Regulation | Amendment | Rationale for Amendment |
|---|---|---|---|
| 20 | **§ 635.5(d)** *Tournament operators.* A tournament operator must notify NMFS of the purpose, dates, and location of the tournament conducted from a port in an Atlantic coastal state, including the U.S. Virgin Islands and Puerto Rico, at least 4 weeks prior to commencement of the tournament. NMFS will notify a tournament operator in writing, when his or her tournament has been selected for reporting. The tournament operator that is selected must maintain and submit to NMFS a record of catch and effort on forms available from NMFS. Tournament operators must submit completed forms to NMFS, at an address designated by NMFS, postmarked no later than the 7th day after the conclusion of the tournament and must attach a copy of the tournament rules. | **§ 635.5(d)** *Tournament operators.* A tournament operator must register with the NMFS' HMS Management Division all tournaments that are conducted from a port in an Atlantic coastal state, including the U.S. Virgin Islands and Puerto Rico, at least 4 weeks prior to commencement of the tournament by indicating the purpose, dates, and location of the tournament. Tournament registration is not considered complete unless the operator has received a confirmation number from the NMFS' HMS Management Division. NMFS will notify a tournament operator in writing when his or her tournament has been selected for reporting. Tournament operators that are selected to report must maintain and submit to NMFS a record of catch and effort on forms available from NMFS. Tournament operators must submit the completed forms to NMFS, at an address designated by NMFS, postmarked no later than the 7th day after the conclusion of the tournament, and must attach a copy of the tournament rules. | Clarifies the specific line office that HMS tournament operators must notify and register with. Indicates that a confirmation number is necessary to complete the registration process. |
| 21 | **§ 635.21(a)(2)** If a billfish is caught by a hook, the fish must be released by cutting the line near the hook or by using a dehooking device, in either case without removing the fish from the water. | **§ 635.21(a)(2)** If a billfish is caught by a hook and not retained, the fish must be released by cutting the line near the hook or by using a dehooking device, in either case without removing the fish from the water. | Clarifies that billfish caught by a hook *and not retained* must be released using specified protocols. Without clarification, the implication may be that billfish caught by hook must always be released. |
| 22 | **§ 635.21(c)(1)** From August 1, 1999, through November 30, 2000, no person may deploy a pelagic longline that is more than 24 nautical mile (44.5 km) in length in the Mid-Atlantic Bight. | **This paragraph is revised with new, non-related regulations.** | Removes a requirement that has expired. |

| Item Number | Current Regulation | Amendment | Rationale for Amendment |
|---|---|---|---|
| 23 | **§ 635.21(c)(2)(ii)** In the Charleston Bump closed area from March 1 through April 30, 2001, and from February 1 through April 30 each calendar year thereafter; | **§ 635.21(c)(2)(ii)** In the Charleston Bump closed area from February 1 through April 30 each calendar year; | Removes dates that have passed. |
| 24 | **§ 635.21(c)(2)(iii)** In the East Florida Coast closed area at any time beginning at 12:01 a.m. on March 1, 2001; | **§ 635.21(c)(2)(iii)** In the East Florida Coast closed area at any time; | Removes dates that have passed. |
| 25 | **§ 635.21(c)(2)(iv)** In the Desoto Canyon closed area at any time beginning at 12:01 a.m. on November 1, 2000; | **§ 635.21(c)(2)(iv)** In the Desoto Canyon closed area at any time; | Removes dates that have passed. |
| 26 | **§ 635.21(c)(2)(v)** In the Northeast Distant closed area at any time, unless persons onboard the vessel comply with the following: * * * | **§ 635.21(c)(2)(v)** In the Northeast Distant gear restricted area at any time, unless persons onboard the vessel comply with the following: * * * | Amends title of the Northeast Distant closed area to reflect recent amendments to the regulations governing the area. |
| 27 | Second sentence of **§ 635.21(e)(1)** currently reads, "When fishing for Atlantic tunas other than BFT, fishing gear authorized for any Atlantic Tunas permit category may be used, except that purse seine gear may only be used on board vessels permitted in the Purse Seine category and pelagic longline gear may be used only on board vessels issued an Atlantic Tunas Longline category tuna permit as well as ILAPs or LAPs for both swordfish and sharks." | Second sentence of **§ 635.21(e)(1)** proposed to be amended as, "When fishing for Atlantic tunas other than BFT, primary fishing gear authorized for any Atlantic Tunas permit category may be used, except that purse seine gear may only be used on board vessels permitted in the Purse Seine category and pelagic longline gear may be used only on board vessels issued an Atlantic Tunas Longline category tuna permit and a LAP other than handgear for swordfish, and a LAP for sharks."<br>**NOTE –** The first sentence in this paragraph is modified pursuant to regulatory changes described in the "Authorized Fishing Gear" section. | Removes references to Initial Limited Access Permits (ILAPs), which are no longer issued. Consistent with existing regulations, reiterates that vessels issued swordfish handgear permits cannot be issued an Atlantic Tunas Longline category permit because the vessel cannot use longline gear to catch swordfish. |

| Item Number | Current Regulation | Amendment | Rationale for Amendment |
|---|---|---|---|
| **28** | **§ 635.21(e)(4)(iii)** A person aboard a vessel issued a directed handgear ILAP or LAP for Atlantic swordfish may not fish for swordfish with any gear other than handgear. * * * | **§ 635.21(e)(4)(iii)** A person aboard a vessel issued or required to be issued a directed handgear LAP for Atlantic swordfish may not fish for swordfish with any gear other than handgear. * * *<br>**NOTE –** The remainder of this paragraph is modified pursuant to regulatory changes described in the "Authorized Fishing Gear" section. | Removes references to Initial Limited Access Permits (ILAPs), which are no longer issued. |
| **29** | The third sentence of **§635.22(c)** currently reads, "No prohibited sharks from the management unit, which are listed in table 1(d) of Appendix A to this part, may be retained." | The third sentence of **§635.22(c)** is amended to be, "No prohibited sharks, including parts or pieces of prohibited sharks, from the management unit, which are listed in table 1 of Appendix A to this part under prohibited sharks, may be retained." | Clarifies that parts and pieces of prohibited sharks may not be retained. |
| **30** | **§ 635.23(f)(3) –** For pelagic longline vessels fishing in the Northeast Distant closed area, as defined under §635.2, under the exemption specified at §635.21(c)(2)(v), all BFT taken incidental to fishing for other species while in the Northeast Distant closed area may be retained up to a maximum of 25 mt for all vessels so authorized, notwithstanding the retention limits and target catch requirements specified in paragraph (f)(1) of this section. | **§ 635.23(f)(3) –** For pelagic longline vessels fishing in the Northeast Distant gear restricted area under the exemption specified at §635.21(c)(2)(v), all BFT taken incidental to fishing for other species while in that area may be retained up to the available quota as specified in §635.27(a), notwithstanding the retention limits and target catch requirements specified in paragraph (f)(1) of this section. Once the available quota as specified in §635.27(a) has been attained, the target catch requirements specified in paragraph (f)(1) of this section apply.<br>**NOTE –** Much of the regulatory text in this paragraph is modified pursuant to Issue 10 in the "Regulatory Housekeeping" section. | Changes the title of the NED closed area to reflect recent amendments to the regulations governing the area. |
| **31** | **§ 635.24(a)(1)** Persons who own or operate a vessel that has been issued a directed ILAP or LAP for shark may retain, possess or land no more than 4,000 lb (1,814 kg), dw, of LCS per trip. | **§ 635.24(a)(1)** Persons who own or operate a vessel that has been issued a directed LAP for shark may retain, possess or land no more than 4,000 lb (1,814 kg), dw of LCS per trip. | Removes references to Initial Limited Access Permits (ILAPs), which are no longer issued. |

| Item Number | Current Regulation | Amendment | Rationale for Amendment |
|---|---|---|---|
| 32 | **§ 635.24(a)(2)** Persons who own or operate a vessel that has been issued an incidental catch ILAP or LAP for sharks may retain, possess or land no more than 5 LCS and 16 SCS and pelagic sharks, combined per trip. | **§ 635.24(a)(2)** Persons who own or operate a vessel that has been issued an incidental catch LAP for sharks may retain, possess or land no more than 5 LCS and 16 SCS and pelagic sharks, combined, per trip. | Removes references to Initial Limited Access Permits (ILAPs), which are no longer issued. |
| 33 | | Add a new paragraph at **§635.24(a)(3)** to read as follows, "Persons who own or operate a vessel that has been issued an incidental or directed LAP for sharks may not retain, possess, land, sell, or purchase a prohibited shark, including parts or pieces of prohibited sharks, which are listed in Table 1 of Appendix A to this part under prohibited sharks." | Clarifies existing regulations regarding the retention, possession, sale and purchase of prohibited sharks by also including parts and pieces of prohibited sharks. |
| 34 | **§ 635.24(b)(1)** Persons aboard a vessel that has been issued an incidental ILAP or LAP for swordfish may retain, possess, or land no more than two swordfish per trip in or from the Atlantic Ocean north of 5° N. lat. | **§ 635.24(b)(1)** Persons aboard a vessel that has been issued an incidental LAP for swordfish may retain, possess, or land no more than two swordfish per trip in or from the Atlantic Ocean north of 5° N. lat. | Removes reference to Initial Limited Access Permits (ILAPs), which are no longer issued. |
| 35 | **§ 635.24(b)(2)** Persons aboard a vessel in the squid trawl fishery that has been issued an incidental ILAP or LAP for swordfish may retain, possess, or land no more than five swordfish per trip in or from the Atlantic Ocean north of 5° N. lat. * * * | **§ 635.24(b)(2)** Persons aboard a vessel in the squid trawl fishery that has been issued an incidental LAP for swordfish may retain, possess, or land no more than five swordfish per trip in or from the Atlantic Ocean north of 5° N. lat. * * * | Removes reference to Initial Limited Access Permits (ILAPs), which are no longer issued. |
| 36 | **§ 635.27(a)(3)** * * * In addition, 25 mt shall be allocated for incidental catch by pelagic longline vessels fishing in the Northeast Distant closed area, as defined under §635.2, under the exemption specified at §635.21(c)(2)(v). | **§ 635.27(a)(3)** * * * In addition, 25 mt shall be allocated for incidental catch by pelagic longline vessels fishing in the Northeast Distant gear restricted area as specified at §635.23(f)(3). | Changes title of the NED closed area to reflect recent regulatory changes to the area. |
| 37 | **§ 635.71(a)(7)** Fail to allow an authorized agent of NMFS to inspect and copy reports and records, as specified in § 635.5(e) or § 635.32. | **§ 635.71(a)(7)** Fail to allow an authorized agent of NMFS to inspect and copy reports and records, as specified in § 635.5(e) and (f), or § 635.32. | Adds an additional reference in this prohibition to § 635.5(f) – *Additional data and inspection.* |

| Item Number | Current Regulation | Amendment | Rationale for Amendment |
|---|---|---|---|
| **38** | **§ 635.71(a)(8)** Fail to make available for inspection an Atlantic HMS or its area of custody, as specified in § 635.5(g). | **§ 635.71(a)(8)** Fail to make available for inspection an Atlantic HMS or its area of custody, as specified in § 635.5(e) and (f). | Corrects an obsolete reference to § 635.5(g) and replaces with § 635.5 (e) and (f). |
| **39** | **§ 635.71(a)(37)** Fail to report to NMFS, at the number designated by NMFS, the incidental capture of listed whales with shark gillnet gear and sea turtle mortalities associated with pelagic longline gear as required by § 635.5. | **§ 635.71(a)(37)** Fail to report to NMFS, at the number designated by NMFS, the incidental capture of listed whales with shark gillnet gear as required by § 635.5. | Removes a duplicative reporting requirement. Captured sea turtles would still be required to be reported in PLL logbooks, so no information is lost. |
| **40** | **§ 635.71(b)(22)** As the owner or operator of a purse seine vessel, fail to comply with the requirements for weighing, measuring, and information collection specified in § 635.30(a)(2). | **§ 635.71(b)(22)** As the owner or operator of a purse seine vessel, fail to comply with the requirement for possession at sea and landing of BFT under § 635.30(a). | Revises language referencing a paragraph that has been removed by referencing the appropriate paragraph. |
| **41** | **§ 635.71(d)(10)** Retain, possess, sell, or purchase a prohibited shark, as specified under § 635.22(c) and § 635.27(b)(1) or fail to disengage any hooked or entangled prohibited shark with the least harm possible to the animal as specified at § 635.21(d)(3). | **§ 635.71(d)(10)** Retain, possess, sell, or purchase a prohibited shark, including parts or pieces of prohibited sharks, as specified under §§ 635.22(c), 635.24(a)(3), and 635.27(b)(1) or fail to disengage any hooked or entangled prohibited shark with the least harm possible to the animal as specified at §635.21(d)(3). | Adds a reference to a new paragraph at § 635.24(a)(3), which includes parts and pieces of prohibited sharks. |
| **42** | **§ 635.71(d)(11)** Falsify information submitted under § 635.16(d)(2) or (d)(4) in support of an application for an ILAP or an appeal of NMFS' denial of an ILAP for shark. | Revise **§ 635.71(d)(11)** with regulatory language pursuant to "HMS Identification Workshops" section. | Removes a cross-reference that has been removed. ILAPs are no longer being issued, and appeals are complete. |
| **43** | **§ 635.71(e)(11)** Falsify information submitted under §635.16(d)(2) or (d)(4) in support of an application for an ILAP or an appeal of NMFS' denial of an initial limited access permit for swordfish. | Revise **§ 635.71(e)(11)** with regulatory language pursuant to "Authorized Gears" section. | Removes a cross-reference that has been removed. ILAPs are no longer being issued, and appeals are complete. |

| Item Number | Current Regulation | Amendment | Rationale for Amendment |
|---|---|---|---|
| 44 | **§ 300.182(d)** *Duration.* Any permit issued under this section is valid until December 31 of the year for which it is issued, unless suspended or revoked. | **§ 300.182(d)** *Duration.* Any permit issued under this section is valid for the period specified on it, unless suspended or revoked. | Modifies the expiration date of the HMS International Trade Permit. |
| 45 | **§ 635.22(b)** *Billfish*. No longbill spearfish from the management unit may be possessed shoreward of the outer boundary of the EEZ. | **§ 635.22(b)** *Billfish*. No longbill spearfish from the management unit may be taken, retained, or possessed shoreward of the outer boundary of the EEZ. | Strengthens longbill spearfish regulations, and is consistent with similar language regarding other species. |

#### *2.3.4.2 Alternatives*

The issues being addressed in this section include changes in definitions, clarifications, and amendments for which alternatives have been developed and analyzed. A description of each issue is provided, followed by a description of the alternatives being considered.

<u>Issue 1: Definitions of Pelagic and Bottom Longline</u>

The HMS time/area closures that are currently in effect apply specifically to either pelagic or bottom longline gear (*i.e*., the Desoto Canyon, East Florida Coast, Charleston Bump, Mid-Atlantic Shark, and Northeastern United States Closed Areas). Therefore, to determine compliance with the closed area restrictions, it is optimal for the two gear types to be clearly differentiable. In the current regulations, the difference is articulated by general reference to the presence of weights/floats capable of anchoring/supporting the mainline on/in the seafloor/water column. Problems have arisen because bottom longline vessel operators sometimes possess and utilize floats on bottom longline gear, and pelagic longline vessel operators sometimes possess and utilize weights on pelagic longline gear. In these situations, it may be difficult to determine if the weights are capable of anchoring the mainline on the seafloor, or if the floats are capable of supporting the mainline in the water column. NMFS is considering amending the definitions for pelagic and bottom longlines at §§ 635.2, 635.21(c), and 635.21(d), or establishing additional restrictions or possession limits on these gears when fishing in any of the HMS time/area closures.

Alternative I1(a) Retain current definitions for pelagic and bottom longline gears (No Action)

This alternative would retain the current definitions for pelagic and bottom longlines at §§ 635.2, 635.21(c), and 635.21(d). A pelagic longline is defined as a longline that is suspended by floats in the water column and that is not fixed to or in contact with the ocean bottom. For purposes of § 635.21(c), a vessel is considered to have pelagic longline gear onboard when a power-operated longline hauler, a mainline, floats capable of supporting the mainline, and leaders (gangions) with hooks are onboard. A bottom longline is defined as a longline that is deployed with enough weights and/or anchors to maintain contact with the ocean bottom. For purposes of § 635.21(d), a vessel is considered to have bottom longline gear on board when a power-operated longline hauler, a mainline, weights and/or anchors capable of maintaining contact between the mainline and the ocean bottom, and leaders (gangions) with hooks are on board. There are currently no restrictions on the amount of pelagic species that may be possessed when fishing with bottom longline gear in PLL closed areas, and vice verse.

Alternative I1(b) Establish additional restrictions on longline gear in HMS time/area closures by specifying a maximum and minimum allowable number of commercial fishing floats in order to qualify as a bottom or pelagic longline vessel, respectively

This alternative would retain the current definitions for pelagic and bottom longlines at §§ 635.2; 635.21(c); and 635.21(d). However, in addition, this alternative would establish limits on the number of commercial fishing floats that longline fishing vessels must possess onboard to qualify as either a bottom or pelagic longline vessel within the closed areas. Specifically, under this alternative, to be considered a bottom longline vessel in a PLL closed area, the vessel must possess no more than 70 commercial fishing floats onboard or deployed, combined. To be considered a pelagic longline vessel in a BLL closed area, the vessel must possess at least 71 commercial fishing floats onboard or deployed, combined. Examples of commercial fishing floats include bullet floats, poly balls, high flyers, and lobster pot buoys. This alternative was a preferred alternative in the Draft Consolidated HMS FMP.

Alternative I1(c) *Differentiate between pelagic and bottom longline gear based upon the species composition of the catch onboard or landed – Preferred Alternative*

This alternative would retain the current definitions for pelagic and bottom longlines at §§ 635.2, 635.21(c), and 635.21(d). However, in addition, this alternative would establish a five-percent limit (by weight) on the allowable amount of pelagic "indicator" species that bottom longline vessels may possess or land from PLL closed areas, and establish a five-percent limit (by weight) on the allowable amount of demersal "indicator" species that pelagic longline vessels may possess or land from BLL closed areas (measured relative to the total weight of all pelagic and demersal "indicator" species). Specifically, to qualify as a bottom longline vessel when fishing in a PLL closed area, no more than five percent (by weight) of the species possessed or landed may be pelagic "indicator" species, as measured relative to the total weight of all pelagic and demersal "indicator" species. To be considered a pelagic longline vessel when fishing in a BLL closed area, no more than five percent (by weight) of the species possessed or landed may be demersal "indicator" species, as measured relative to the total weight of all pelagic and demersal "indicator" species. The indicator species are listed in Table 1 of Section 4.3.4.

Alternative I1(d) Require time/depth recorders (TDRs) on all HMS longlines

This alternative would require TDRs (data loggers) at pre-specified intervals on all HMS longline fishing gear that is deployed. Under this alternative, the TDRs would have to be operational and able to accurately record the maximum and minimum fishing depths of HMS longline gear using an onboard TDR reader. Pelagic longline gear would be required to remain within the upper two-thirds of the water column while fishing, and bottom longline gear would be required to remain within the bottom third of the water column while fishing.

Alternative I1(e) Base HMS time/area closures on all longlines (PLL and BLL)

This alternative would not differentiate between pelagic and bottom longline gear in the establishment and enforcement of HMS longline closed areas. Specifically, if this alternative were adopted, all longline gear would be prohibited from all HMS longline closed areas.

Issue 2: Shark Identification

Species identification of sharks can be enhanced by the presence of fins. NMFS is considering amending the regulations governing commercial shark landings, possibly at § 635.30(c)(2) and at § 635.71(d)(6), to facilitate shark identification for enforcement and data collection purposes.

Alternative I2(a) Retain current commercial regulations regarding shark landing requirements (No Action)

By retaining the *status quo*, this alternative would allow for the removal of all shark fins prior to landing. Other regulations governing the landing of sharks and shark fins would remain unchanged, as well. As such, Federal commercial shark limited access permit holders would be allowed to eviscerate sharks and remove their heads and fins at sea as long as the ratio between the weight of fins and the weight of carcass does not exceed five percent.

Alternative I2(b) *Require that the $2^{nd}$ dorsal fin and the anal fin remain on all sharks through landing – Preferred Alternative*

This alternative would mandate the retention of the $2^{nd}$ dorsal fin and anal fin on all shark species through landing. Specifically, Federal commercial shark limited access permit holders would be required to have these fins attached to all sharks during offloading. Removal of these fins would only be permissible after the shark is offloaded.

Alternative I2(c) Require that the $2^{nd}$ dorsal fin and the anal fin remain on all sharks through landing, except for lemon and nurse sharks

This alternative would mandate the retention of the $2^{nd}$ dorsal fin and anal fin on all shark species, except for lemon and nurse sharks, through landing. Specifically, Federal commercial shark limited access permit holders would be required to have these fins attached to all sharks, except nurse and lemon sharks, during offloading. Removal of these fins would only be permissible after the shark is offloaded. Due to ease at which nurse and lemon sharks without $2^{nd}$ dorsal and anal fins can be identified, these species would be exempt under this alternative.

Alternative I2(d) Require that all fins remain on all sharks through landing

This alternative would mandate the retention of all fins on all shark species through landing. Federal commercial shark limited access permit holders would be required to have all fins attached to all sharks during offloading. Removal of the fins would only be permissible after the shark is offloaded.

Issue 3: HMS Retention Limits

Currently, HMS retention limits apply to “persons aboard a vessel” (*i.e*., vessel owners and operators). NMFS is considering adding new prohibitions at § 635.71(a)(48) and § 635.71(a)(49) that would address the purchase and sale of HMS by dealers and fishermen in excess of the retention limits specified in § 635.23 and § 635.24. The intent of these prohibitions would be to improve compliance with HMS retention limits by extending the regulations to both of the parties involved in a transaction (*i.e*. “persons aboard a vessel” & buyers).

Alternative I3 (a) Retain current regulations regarding retention limits, with no new prohibitions (No Action)

This alternative would not implement any new prohibitions regarding the purchase and sale of HMS by dealers and fishermen in excess of the retention limits specified in §§ 635.23 and 635.24. As such, compliance with many of the HMS retention limits would remain solely incumbent upon “persons aboard a vessel” (*i.e*., vessel owners and operators). Persons who purchase HMS that were offloaded from an individual vessel in excess of the retention limits would remain unaffected.

Alternative I3(b) *Add new prohibition at § 635.71(a)(48) making it illegal for any person to, “Purchase any HMS that was offloaded from an individual vessel in excess of the retention limits specified in §§ 635.23 and 635.24” – Preferred Alternative*

This alternative would implement a new prohibition at § 635.71(a)(48) making it illegal for any person to, “Purchase any HMS that was offloaded from an individual vessel in excess of the retention limits specified in §§ 635.23 and 635.24.” As such, dealers or buyers would be held responsible for purchases of HMS in excess of the commercial retention limits. This prohibition is intended to improve compliance with HMS retention limits by extending the regulations to both of the parties involved in a transaction. It would reinforce and clarify other existing regulations regarding landings of HMS in excess of commercial retention limits.

Alternative I3(c) *Add new prohibition at § 635.71(a)(49) making it illegal for any person to, “Sell any HMS that was offloaded from an individual vessel in excess of the retention limits specified in §§ 635.23 and 635.24” – Preferred Alternative*

This alternative would implement a new prohibition at § 635.71(a)(49) making it illegal for any person to, “Sell any HMS that was offloaded from an individual vessel in excess of the retention limits specified in §§ 635.23 and 635.24.” As such, vessel owners or operators would be held responsible for sales in excess of HMS retention limits. This prohibition would reinforce and clarify other existing regulations regarding landings of HMS by vessels in excess of commercial retention limits.

Issue 4: Definition of East Florida Coast Closed Area

NMFS is considering amending the definition of the East Florida Coast closed area at § 635.2 by replacing the second coordinate (28° 17’ N. Lat., 79° 12’ W. Long.) with a new coordinate (28° 17’ 10” N. Lat., 79° 11’ 24” W. Long.), so that the outer boundary of the closed area corresponds with the outer boundary of the EEZ, as originally intended. This area was initially described in the FSEIS (NMFS June 14, 2000) and the final rule prepared pursuant to implementation of the closed area (65 FR 47214, August 1, 2000). However, one of the current outer coordinates does not correspond exactly with the EEZ boundary, thus inadvertently leaving a small area open between the closed area and the EEZ. The outer coordinate being considered is approximately 1.02 km (0.55 nm) seaward (eastward) of the current coordinate.

Alternative I4(a) Retain current coordinates for the East Florida Coast closed area (No Action)

This alternative would retain the *status quo* coordinates for the East Florida Coast closed area. One of the outer coordinates does not correspond exactly with the EEZ boundary, thus leaving a small area open between the closed area and the EEZ. Pelagic longline vessels would continue to be allowed to fish in this small region between the closed area and the EEZ.

Alternative I4(b) *Amend the second coordinate of the East Florida Coast closed area to 28° 17’ 10” N. Lat., 79° 11’ 24” W. Long., so that it corresponds with the EEZ – Preferred Alternative*

This alternative would amend the second coordinate of the East Florida Coast closed area. If this alternative were selected, pelagic longline vessels would not be able to fish in the small area that is currently open between the closed area and the EEZ. This modification would meet the intent of the closed area to extend out to the EEZ.

<u>Issue 5: Definition of Handline</u>

Currently, a “handline” is defined as fishing gear consisting of a mainline to which no more than two leaders (gangions) with hooks are attached, and that is released and retrieved by hand, rather than by mechanical means. It has been brought to the Agency’s attention that some vessel operators, both commercial and recreational, may be deploying numerous handlines that are not attached to their vessel in areas that are closed to pelagic longlines and elsewhere. While these vessel operators may be technically compliant with current regulations, this practice may circumvent the original “concept” of handline gear, and could potentially diminish the conservation benefits associated with the PLL closed areas. Therefore, NMFS is considering amending the definition of “handline,” possibly at §§ 635.2 and 635.2l.

Alternative I5(a) Retain the current definition of “handline” at § 635.2 (No Action)

The “No Action” alternative would retain the current definition of “handline,” as described above. As such, the practice of fishing with an unlimited number of unattached handlines would continue to be allowed.

Alternative I5(b) *Amend the definition of “handline” at § 635.2 by requiring that they be attached to, or in contact with, a vessel – Preferred Alternative*

Alternative I5(b) would define a handline as fishing gear that is attached to, or in direct contact with, a fishing vessel and consists of a mainline to which no more than two leaders (gangions) with hooks are attached, and that is released and retrieved by hand, rather than by mechanical means. As such, the practice of fishing with unattached handlines would be disallowed for all HMS commercial and recreational fishing activities. Please see Section 2.3.3 of this document regarding an alternative that would add "buoy gear" to the list of authorized gears for the swordfish handgear fishery.

Alternative I5(c) Require that handlines remain attached to vessels when fishing recreationally and allow unattached handlines when fishing commercially

Alternative I5(c) would require that handlines remain attached to, or in direct contact with, a fishing vessel for all vessels possessing either an HMS Angling category permit; an HMS Charter/headboat permit when fishing on a for-hire trip; or, an Atlantic Tunas General category permit when fishing in a registered HMS tournament. As such, the practice of fishing with unattached handlines would be disallowed when conducting recreational fishing activities, but the practice would be allowed when fishing commercially.

Issue 6: Possession of Billfish on Vessels Issued HMS Commercial Permits

The Atlantic billfish fishery is a recreational fishery and the sale of Atlantic billfish is prohibited. Furthermore, Atlantic billfish may only be harvested by rod and reel, and persons may not currently possess, take, or retain billfish if pelagic longline gear is onboard the vessel. NMFS is considering amendments that would reinforce the recreational nature of the Atlantic billfish fishery by eliminating a minor loophole that exists, whereby the possession or retention of billfish is not prohibited if commercial gears other than pelagic longline are onboard a vessel. As such, persons aboard HMS-permitted vessels may potentially fish for and possess Atlantic billfish for non-commercial purposes using rod and reel when other commercial gear is onboard. Also, vessel operators might incidentally capture and possess billfish caught on other commercial gears and illegally retain the fish by indicating that it was caught using rod and reel. Therefore, NMFS is considering amendments to prohibit the possession or retention of billfish on all vessels issued HMS commercial permits.

Alternative I6(a) Retain current regulations regarding the possession of Atlantic billfish (No Action)

The "No Action" alternative would allow the possession or retention of billfish when commercial gears, other than pelagic longlines, are onboard the vessel. As such, persons may potentially fish for and possess Atlantic billfish for non-commercial purposes using rod and reel, when other commercial gear is onboard. The "No Action" alternative does not specify which permit holders may possess or retain an Atlantic billfish taken from its management unit.

Alternative I6(b) *Prohibit vessels issued HMS commercial permits and operating outside of a tournament from possessing, retaining, or taking Atlantic billfish from the management unit – Preferred Alternative*

Alternative I6(b) would prohibit the possession or retention of billfish on all vessels that have been issued HMS commercial permits. Only vessel owners possessing either an HMS Angling, HMS Charter/headboat permit, or an Atlantic Tunas General category (when fishing in a registered HMS tournament) permit would be allowed to possess or retain an Atlantic billfish taken from its management unit with rod and reel. If this alternative were selected, the regulations for all HMS commercial fisheries would be consistent with current regulations in effect for the pelagic longline fishery. This alternative would further reinforce and clarify the recreational nature of the Atlantic billfish fishery.

Issue 7: Bluefin Tuna Dealer Reporting

NMFS is investigating alternative methods of BFT dealer reporting. Currently, BFT dealers are required to manually complete and submit as many as three individual BFT reports (BFT landing reports, bi-weekly BFT reports, and BFT statistical documents for international trade). These reports are then re-entered into databases by NMFS personnel. Recent advances in software technology and web-based applications provide opportunities for dealers to enter and report data with greater efficiency, and with potential reductions in administrative costs for both dealers and NMFS. For example, NMFS' Northeast Regional Office has transitioned to an electronic web-based dealer reporting system and continues to work with dealers to improve the system. Electronic capabilities could also be developed for an HMS BFT system to increase quality control and assurance capabilities, using cross-checks with other databases, data fields, and flags that would facilitate accurate data entry. However, current regulations regarding BFT dealer reporting and recordkeeping require that dealers submit written reports, either in the mail or via FAX transmittal. To provide additional electronic reporting flexibility, as described above, it is necessary to amend the HMS regulations to specify that BFT dealers may submit these reports electronically over the Internet if they choose to do so, or are required to do so.

Alternative I7(a) Retain the current regulations regarding bluefin tuna dealer reporting (No Action)

Under this alternative the regulations regarding BFT dealer reporting would remain unchanged. Potentially, dealers that have the capacity and interest to report electronically would not be able to do so because the current requirements specifically state that reports must be written and mailed or faxed (*i.e.*, fax for landing reports; fax or standard mail for bi-weekly reports; fax or standard mail for statistical documents accompanying imported BFT; standard mail for statistical documents accompanying exported BFT).

Alternative I7(b) *Amend the HMS regulations to provide an option for Atlantic tunas dealers to submit required BFT reports using the Internet – Preferred Alternative*

Under this alternative, the regulations would be slightly modified to add text under each BFT dealer reporting requirement so that dealers may also electronically submit the required report if they choose to do so, using an on-line tool or webpage. All *status quo* methods of providing hand-written reports and documentation via mail or fax would remain available and permissible. Electronic submission would be provided as an option, and would not be mandatory. Investigations are still underway regarding the feasibility and design of an electronic system and no dates for implementation have yet been set. However, when such a system has been designed, it would be useful to provide interested dealers with the opportunity to test the system and provide feedback for future enhancements. The preferred alternative would provide dealers with the flexibility not only to test the system, but continue to use it should they choose to do so.

Alternative I7(c) Amend the HMS BFT dealer reporting regulations to require that Atlantic tunas dealers submit BFT reports electronically, with specific exceptions

This alternative proposes to adjust the regulations to require all BFT dealers, with some exceptions, to submit all BFT reports electronically either using a web-based application, or using software on a private computer with the data being transmitted over the Internet. The intent of this alternative would be to standardize reporting, reduce administrative burdens, and ensure the new system is used. All options to submit written reports via mail or fax would be eliminated with certain specific exemptions, such as for dealers falling below an established economic threshold, or for dealers who only report minimal numbers of fish on an infrequent basis.

Issue 8: "No-Fishing," "Cost-Earnings," and "Annual Expenditures" Reporting Forms

Presently, if commercial HMS permit holders (*i.e.*, HMS Charter/headboat, Atlantic Tunas, and commercial shark and swordfish permit holders) are selected for reporting, they are required to submit logbooks to NMFS postmarked within seven days of offloading any Atlantic HMS. NMFS supplies logbook forms to all selected vessels. These forms consist of a fishing report (catch, discards, effort and fishing area data), a "no-fishing" reporting form if no fishing took place during the preceding month, and trip and annual "cost-earnings" reporting forms. The reported information is used to conduct stock assessments, monitor quotas, prevent overfishing, and estimate the economic impacts of different management measures. There has been some confusion as to whether the "no-fishing" reporting form and the "cost-earnings" reporting forms are a required component of the logbook, and exactly when they must be submitted. Therefore, NMFS is considering amendments to require the submission of a "no-fishing" reporting form, and to specify that the report must be postmarked no later than seven days after the end of the month. Similarly, the "cost-earnings" and "annual expenditures" reporting forms would need to be submitted consistent with the instructions on the forms. The Paperwork Reduction Act (PRA) reporting burden for these information collections is currently approved under the PRA submission for Atlantic HMS vessel logbooks (OMB Control Number 0648-0371). A requirement to submit the "no-fishing" report form, and the trip "cost-earnings" and "annual expenditures" reporting forms within a certain timeframe would be new, however it is consistent with current HMS requirements and with other NMFS' Southeast Regional regulations. These modifications would clarify HMS logbook reporting requirements.

Alternative I8(a) Maintain the existing regulations regarding submission of logbooks (No Action)

The "No Action" alternative would retain the existing regulations regarding the submission of HMS vessel logbooks at § 635.5(a)(1). There are currently no specific regulations to submit "no-fishing," "cost-earnings," and "annual expenditure" reporting forms to NMFS within a certain timeframe.

Alternative I8(b) *Require submission of "no-fishing" reporting forms for selected vessels if no fishing trips occurred during the preceding month, postmarked no later than seven days after the end of the month – Preferred Alternative*

Alternative I8(b) would amend the HMS regulations at § 635.5(a)(1) to require the submission of "no-fishing" reporting forms for selected vessels if no fishing trips occurred during the preceding month to be postmarked no later than seven days after the end of the month. This alternative would clarify HMS logbook reporting requirements and provide important information to conduct stock assessments, monitor quotas, and prevent overfishing.

Alternative I8(c) *Require submission of the trip "cost-earnings" reporting form for selected vessels 30 days after a trip, and the" annual expenditures" report form by the date specified on the form – Preferred Alternative*

Alternative I8(c) would amend the HMS regulations to require the submission of trip "cost-earnings" reporting forms for selected vessels 30 days after a trip, and the "annual expenditures" report form by the date specified on the form (presently January 31st). This alternative would better clarify HMS reporting requirement and provide important information to estimate the economic impacts of different management measures.

Issue 9: Non-Tournament Recreational Landings Reporting

HMS regulations currently specify that anglers are required to report non-tournament recreational landings of Atlantic billfish and swordfish, whereas other HMS regulations specify that vessel owners are required to report recreational landings of bluefin tuna under the Angling category. NMFS is considering clarifying that owners of vessels permitted, or required to be permitted, in the Atlantic HMS Angling or Atlantic HMS Charter/headboat category (or their designee) must report all non-tournament recreational landings of billfish and swordfish. This action is being considered to remove inconsistencies in reporting requirements and to clarify NMFS' intent that the vessel owner, rather than the angler, is responsible for reporting non-tournament recreational landings of Atlantic billfish and swordfish.

Alternative I9(a) Retain existing regulations at § 635.5(c)(2) requiring anglers to report non-tournament recreational landings of North Atlantic swordfish and Atlantic billfish (No Action)

Alternative I9(a) would retain existing HMS regulations that specify that anglers are required to report non-tournament recreational landings of Atlantic billfish and swordfish. These regulations are inconsistent with other HMS regulations specifying that vessel owners are required to report recreational landings of bluefin tuna under the Angling category.

Alternative I9(b) *Require vessel owners (or their designee) to report non-tournament recreational landings of North Atlantic swordfish and Atlantic billfish – Preferred Alternative*

Alternative I9(b) would amend the HMS regulations to specify that vessel owners (or their designee) are required to report non-tournament recreational landings of Atlantic billfish and swordfish.  The vessel owner would be responsible for reporting, but the owner's designee could fulfill the requirement.  This alternative would be consistent with other HMS regulations specifying that vessel owners are required to report recreational landings of bluefin tuna under the Angling category.

Issue 10: Pelagic Longline 25 mt (ww) NED Incidental BFT Allocation

In November 2002, ICCAT recommended an annual U. S. Total Allowable Catch (TAC) of western Atlantic BFT of 1,489.6 mt (ww).  A specific allocation of 25 mt (ww) was included in this TAC to account for the incidental catch of BFT by longline fisheries directed on other species "in the vicinity of the management boundary area" for the eastern and western BFT stocks.  This area was defined by NMFS in the 2003 BFT annual specification as the Northeast Distant (NED) statistical reporting area (approximately the Grand Banks fishing grounds) (68 FR 56783, October 2, 2003).  The regulatory text at 50 CFR 635.27(a)(3) was revised to include this additional allocation, and specifically states that "25 mt shall be allocated for incidental catch by pelagic longline vessel fishing in the NED."

As the language contained in the ICCAT recommendation is not explicit regarding application of any unharvested quota to the following year's quota, NMFS prefers to clarify the regulatory text and the procedures implementing that text, as it directly relates to this specific set-aside.  Since the implementation of the 25 mt (ww) recommendation, NMFS has allocated an additional 25 mt (ww) for this incidental catch each year.  However, because previous year's longline activity has not resulted in full incidental set-aside quota attainment, NMFS has carried forward un-utilized quota and added it to the subsequent fishing year's annual 25 mt (ww) allocation.  This has resulted in revised totals that exceed 25 mt (ww).  This accumulation of incidental quota has led to revised set-aside quotas exceeding that of the ICCAT recommended amount and therefore, may not fully reflect the intent of the recommendation.  Several alternatives are presented below to clarify the amount of available incidental BFT quota for pelagic longline activity in the vicinity of the NED statistical reporting area.

Alternative I10(a): Retain the current regulations specifically referring to 25 mt (ww) (No Action)

Under this alternative, the status quo regulatory text implementing this ICCAT recommendation would remain unchanged and would indicate that 25 mt (ww) shall be allocated for incidental catch of BFT by pelagic longline vessels fishing in the NED.  This alternative would not clarify the applicability of quota carry-over provisions to this set-aside quota, and may allow for implementing practices to not fully reflect the original intent of the recommendation.  Under this alternative, NMFS would allocate 25 mt (ww) for this incidental catch on an annual basis.  If the previous year's longline activity has not resulted in full incidental set-aside quota attainment, NMFS would carry forward un-utilized quota and add it to the subsequent fishing year's 25 mt (ww) allocation.  If the previous year's longline activity has exceeded the incidental set-aside quota, NMFS would deduct the overharvest from the subsequent fishing year's 25 mt (ww) allocation.  Thus, this alternative may result in a revised quota that differs from the 25 mt (ww).

Alternative I10(b): Modify the HMS regulations to state that "In addition, each year, 25 mt (ww) will be allocated for incidental catch by pelagic longline vessels fishing in the NED"

Under Alternative I10(b), the regulatory text would be modified to include the phrase "each year" to clarify that the annual baseline allocation equals 25 mt (ww), but the total available quota for a given year would not be limited and may be modified to account for under/overharvests from prior year's activity. This alternative would clarify that carryover provisions apply to this set-aside quota. This was a preferred alternative in the Draft HMS FMP.

Alternative I10(c): *Conduct additional discussions at ICCAT regarding quota rollovers and adjust quotas allocated to account for bycatch related to pelagic longline fisheries in the vicinity of the management area boundary accordingly Preferred Alternative*

Under this alternative, the United States would conduct additional discussions at the annual ICCAT meeting regarding the long-term implications of allowing unused BFT quota from the previous year being added to the subsequent year's allocation that can be retained. Depending on the results of any additional discussions at ICCAT, the regulations and operational procedures that account for BFT bycatch related to pelagic longline fisheries in the vicinity of the management area boundary may need to be further amended in the future. In the interim, NMFS would maintain the current regulatory text implementing the ICCAT recommendation, as described in alternative I10(a), but would amend the current practice of allowing under/overharvest of this set-aside allocation to be rolled into, or deducted from, the subsequent fishing year's set-aside allocation. Therefore, regardless of the amount of the set-aside harvested or unused in a given year, the balance would return to 25 mt (ww) at the start of each fishing year. If landings were to exceed the 25 mt (ww) allotment, they would be accounted for via Longline category quota that applies to the entire Western Atlantic management area.

<u>Issue 11: Permit Condition for Recreational Trips</u>

In the HMS regulations, as a condition of their permits, vessels that have a commercial shark or swordfish permit must currently comply with Federal regulations regardless of where vessels are fishing, unless a state has more restrictive regulations (50 CFR § 635.4(a)(10)). However, vessels fishing recreationally for sharks, swordfish, billfish, and tunas in a few states are currently able to fish under state regulations while in state waters, and under Federal regulations when in Federal waters. This has generated confusion due to the differences between state and Federal regulations and the inability to verify whether or not a particular fish onboard a vessel was caught in state waters or Federal waters. The alternatives below consider modifying the *status quo* to remove this ambiguity.

Alternative I11(a) No permit condition for recreational trips (No Action)

Under this alternative, the regulations would remain as they currently are. Thus, vessels issued an HMS Angling permit, an Atlantic Tunas General Category permit that was participating in a registered tournament, or an HMS Charter/headboat permit that was on a for-hire trip would fish under Federal requirements in Federal waters and under state requirements in state waters.

Alternative I11(b) *Require recreational vessels with a Federal permit to abide by Federal regulations, regardless of where they are fishing, unless a state has more restrictive regulations - Preferred Alternative*

Under this alternative, vessels that have been issued an HMS Angling permit, an Atlantic Tunas General category permit that was participating in a registered tournament, or an HMS Charter/headboat permit on a for-hire trip would be required to fish for, retain, or possess Atlantic HMS in accordance with Federal regulations regardless of fishing location, unless the state where the fish is caught has more restrictive regulations. For example, if the Federal bag limit is three fish per vessel, and the state bag limit is two fish per vessel, a vessel with a Federal permit fishing in state waters would be limited to two fish per vessel. However, if the Federal bag limit is three fish per vessel, and the state bag limit is four fish per vessel, a vessel with a Federal permit fishing in state waters would be limited to three fish per vessel. Vessels that have not been issued a Federal permit that allows for recreational Atlantic HMS fishing would need to abide by state regulations when fishing for HMS in state waters. A vessel without a Federal permit cannot legally fish in Federal waters for Atlantic HMS.

# CHAPTER 3 TABLE OF CONTENTS

## CHAPTER 3 LIST OF TABLES

# CHAPTER 3 LIST OF FIGURES

## 3.0 DESCRIPTION OF AFFECTED ENVIRONMENT

This Chapter serves several purposes. As part of an EIS, this Chapter describes the affected environment (the fisheries, the gears used, the communities involved, etc.). The description should provide a view on the current conditions and serves as a baseline against which to compare impacts of the alternatives. This Chapter also serves as the 2006 SAFE Report required under the guidelines for National Standard 2 of the Magnuson-Stevens Act (50 CFR 600.315(e)). The SAFE Report should provide a summary of information concerning the biological status of the stocks; the marine ecosystems in the fishery management unit; the social and economic condition of the fishing interests, fishing communities, and fish processing industries; and, the best available scientific information concerning the past, present, and possible future condition of the stocks, ecosystems, and fisheries.

### 3.1 Introduction to HMS Management and HMS Fisheries

Atlantic HMS fisheries are primarily managed directly by the Secretary of Commerce, who designated that responsibility to NMFS. The HMS Management Division within NMFS is the lead in developing regulations for HMS fisheries, although some actions (*e.g.*, Large Whale Take Reduction Plan) are taken by other NMFS offices outside of the HMS Management Division if the main legislation (*e.g.*, Marine Mammal Protection Act) driving the action are not the Magnuson-Stevens Act or ACTA. Because of their migratory nature, HMS fishery management necessitates management at the international, national, and state levels. NMFS primarily coordinates the management of HMS fisheries in Federal waters (domestic) and the high seas (international) while individual States establish regulations for HMS in their own waters. There are exceptions to this generalization. For example, Federal bluefin tuna regulations apply in most state waters, and Federal shark and swordfish fishermen, as a condition of their permit, are required to follow Federal regulations in all waters unless that state has more restrictive regulations (see Sections 2.3.4 and 4.3.4 for a preferred alternative that would apply the permit condition to recreationally caught HMS). Additionally, in 2005, the Atlantic States Marine Fisheries Commission agreed to develop an interstate coastal shark FMP. Once complete, this interstate FMP would coordinate management measures among all states along the Atlantic coast (Florida to Maine). NMFS is participating in the development of this interstate FMP. A brief history of HMS management is provided in sections 3.1.1 and 3.1.2.

Generally, on the domestic level, NMFS implements international agreements, as appropriate, and management measures that are required under domestic laws such as the Magnuson-Stevens Act. While NMFS does not generally manage HMS fisheries in state waters, states are invited to send representatives to AP meetings and to participate in stock assessments, public hearings, or other fora. NMFS is working to improve its communication and coordination with state agencies. In the past year, NMFS has reviewed the shark regulations of several states and has asked for some states to consider changing their regulations to become more consistent with Federal regulations. As of May 2006, this request resulted in changes and dialogs with certain states regarding the regulations such as the Commonwealth of Virginia and the State of Florida. Additionally, as a result of ASMFC's decision to develop an interstate FMP, the State of Maine opened a dialog with the NMFS regarding shark regulations. See section 3.1.5 for more information regarding state regulations by state.

On the international level, NMFS participates in the stock assessments conducted by ICCAT's SCRS and in the annual ICCAT meetings. The stock assessments and management recommendations or resolutions are listed on ICCAT's website at http://www.iccat.es/. NMFS also actively participates in other international bodies that could affect U.S. fishermen and the fishing industry including CITES and FAO. A summary of 2005 ICCAT accomplishments is provided in section 3.1.4 below. NMFS expects ICCAT to assess a number of stocks in 2006 including marlin, bluefin tuna, and swordfish. More information on the current status of HMS and the dates of the next ICCAT stock assessments is provided in section 3.2.

### 3.1.1 History of Atlantic Tunas, Swordfish, and Shark Management

This section and section 3.1.2 give a relatively brief history of the management of HMS. This history is organized by the previous FMPs, with Atlantic tunas, swordfish, and sharks in one section and Atlantic billfish in the next section. For more detail regarding the history of management, please see the original documents. Proposed rule, final rules, and other official notices can be found in the Federal Register at http://www.gpoaccess.gov/fr/index.html. Supporting documents can be found on the HMS Management Division's webpage at http://www.nmfs.noaa.gov/sfa/hms. Documents can also be requested by calling the HMS Management Division at (301) 713-2347. Section 3.1.3 provides information on more recent actions.

#### 3.1.1.1 Pre-1999 Atlantic Tunas Management

Unless otherwise specified, the following history is a combination of a variety of sources including ICCAT recommendations, the 1999 FMP for Atlantic Tuna, Swordfish, and Sharks, and a 1996 document on the historic rationale and effectiveness of the regulations for U.S. Atlantic BFT fisheries (NMFS, 1996).

Bigeye, albacore, yellowfin, and skipjack (BAYS) tunas, as well as bluefin tuna have been exploited in the western Atlantic for many years. In the early 1900s, a sport fishery developed for small and medium tunas off New York and New Jersey, and for giant bluefin tuna in the Gulf of Maine. The rod and reel fishery expanded rapidly during the 1950s and 1960s, as hundreds of private, charter, and partyboats targeted tunas along the Mid-Atlantic coast. This recreational fishery continues today from Cape Hatteras to the Canadian border. In addition, it is locally important in the Straits of Florida. Sport catches of BAYS, particularly yellowfin tuna, are also made in the Gulf of Mexico.

Until the late 1950s, the U.S. commercial fishery for tunas employed mostly harpoons, handlines, and traps. There was no commercial market for bluefin tuna, and giant bluefin tuna (greater than 310 pounds (lb)) were regarded as a nuisance because of the damage they caused to fishing gear. Much of the bluefin tuna catch was incidental to operations targeting other species. In 1958, commercial purse seining for Atlantic tunas began with a single vessel in Cape Cod Bay and expanded rapidly into the region between Cape Hatteras and Cape Cod during the early 1960s. The purse seine fishery between Cape Hatteras and Cape Cod was directed mainly at small and medium bluefin tuna, and at skipjack tuna, all for the canning industry. North of Cape Cod, purse seining was directed at giant bluefin tuna. A pelagic longline fishery for Atlantic tunas also developed rapidly during the 1960s, comprised mainly of Japanese vessels fishing in the Gulf of Mexico. Today U.S. pelagic longline vessels target bigeye and yellowfin tuna, and catch bluefin tuna incidentally.

The U.S. handgear fishery for Atlantic tunas is mainly a summer through early winter fishery. The recreational tuna fishery takes place mainly in the Mid-Atlantic region through the Gulf of Mexico (GOM). Private vessels targeting tuna for recreational purposes only are permitted in the Angling category, while the charter/headboats targeting tunas are permitted in the Charter/Headboat category. Many fishermen who might normally consider themselves "recreational" fishermen participate in the General category in northeast waters during the summer and fall and are classified as commercial fishermen. Recently, a commercial bluefin tuna fishery has developed off of some south Atlantic states, particularly the State of North Carolina, in the early winter. General category permit holders may sell tuna, and specifically bluefin tuna greater than 73 inches. A 1998 regulation prohibiting the retention of bluefin tuna less than 73 inches by fishermen in the General category clarified the distinction between the commercial and recreational fisheries. The commercial handgear fishery for bluefin tuna occurs mainly in New England, with vessels targeting fish using handline, rod and reel, and harpoon.

*Bluefin Tuna*

Peak yields of bluefin tuna from the western Atlantic (about 8,000 to 19,000 metric tons (mt) whole weight (ww)) occurred between 1963 and 1966 when much of the catch was taken by Asian longline vessels off Brazil. During the late 1960s and 1970s, annual yields averaged about 5,000 mt ww. High catches of juvenile bluefin tuna were sustained throughout the 1960s and into the early 1970s. During the 1960s and 1970s, a North American purse seine fishery for juveniles and the longline fishery, mostly Japanese vessels, usually took 70 to 80 percent of the yield and recreational fisheries usually took 10 percent. By 1973, the United States and other nations began to express concern about the decrease in the abundance of bluefin tuna. In response to this concern, in 1974, ICCAT recommended a minimum size limit of 6.4 kg (14 lb) and recommended that all countries limit fishing mortality to recent (at that time) levels for one year. As a result, the United States limited U.S. harvest by imposing quotas and size limits. In the late 1970s, approximately 10,000 giant bluefin tuna were taken in one year alone from the Gulf of Mexico.

After conducting a series of stock assessments, the ICCAT Standing Committee on Research and Statistics (SCRS) recommended in 1981 that catches of western Atlantic bluefin tuna be reduced to as near zero as possible to stop the decline of the stock and established a 800 mt ww total allowable catch (TAC). This recommendation also prohibited fishing effort in the western Atlantic from transferring to the eastern Atlantic (the stocks were split at $45^0$ W longitude through $10^0$ N latitude before moving to $25^0$ W longitude at the equator). At the 1982 meeting, the TAC was increased to 2,660 mt ww, to be split proportionately between the relevant Contracting Parties. This level was maintained through 1991. Also at the 1982 meeting, ICCAT recommended that there be no directed fishery on bluefin tuna spawning stocks in the western Atlantic in spawning areas such as the Gulf of Mexico.

By the late 1980s, high ex-vessel prices and the increased importance of the Japanese market had blurred the distinction between the commercial and recreational fisheries for bluefin tuna and much of the traditionally recreational catch for medium and giant bluefin tuna was being sold for shipment to Japan. In 1992, NMFS responded by banning the sale of school, large school, and small medium bluefin tuna (27 inches to less than 73 inches curved fork length).

At the 1991 meeting, ICCAT recommended additional measures to prevent further declines in the western Atlantic bluefin tuna stock, including a ten percent reduction in the total allowable catch. In 1993, the western Atlantic bluefin tuna quota was reduced further from 2,394 mt ww to 1,995 mt ww in 1994 and 1,200 mt ww in 1995. At the 1991 meeting, the United States was allocated 693 mt ww per year for both 1993 and 1994. This 1991 recommendation also increased the minimum size to 30 kg (66 lb) or 115 cm (45 in) fork length with a tolerance level of eight percent. Fishermen who caught fish smaller than this size were encouraged to tag and release them.

In 1992, NMFS established base quotas for each permit category in the bluefin tuna fishery based upon the historical share of catch in each of these categories during the period 1983 to 1991. These quotas were used in 1992, 1993, and 1994, with overharvests and underharvests added and subtracted as required by ICCAT, as well as some inseason transfers. At the 1992 ICCAT meeting, ICCAT recommended that by September 1, 1993, all bluefin tuna imports into a Contracting Party be accompanied by an ICCAT Bluefin Tuna Statistical Document that included, among other things, the area that the fish was harvested in, the gear, and a validation by a government official of the flag state of the vessel that harvested the tuna.

The SCRS projections in 1994 indicated that the stock could support higher quota levels and still begin to rebuild, albeit more slowly. Based on the new stock assessment, ICCAT members adopted a recommendation to increase the annual bluefin tuna total allowable catch in the western Atlantic Ocean from 1,995 to 2,200 mt ww. The share allocated to the United States was set at 1,311 mt ww. This allocation reflected trends in fleet size, effort and landings by category, as well as the ICCAT recommendation which specifies that data should be collected for the broadest range of size-classes possible, given size restrictions. At the 1996 meeting, ICCAT recommended an annual western Atlantic bluefin tuna TAC of 2,354 mt ww for 1997 and 1998. The annual quota allocated to the United States for 1997 and 1998 was 1,344 mt ww.

In 1998, the Commission adopted a 20-year Rebuilding Program for the western Atlantic bluefin management area (ICCAT Ref. 98-07) aimed at rebuilding to the stock size that will produce Maximum Sustainable Yield (MSY) by 2018 with a 50 percent or greater probability. The Program states that the TAC for the west would only be adjusted from the 2,500 mt ww level adopted for 2003 – 2004 if SCRS advises that (a) a catch of 2,700 mt ww or more has a 50 percent or greater probability of rebuilding or (b) a catch of 2,300 t or less is necessary to have a 50 percent or greater probability of rebuilding. According to the Program, the MSY rebuilding target can be adjusted according to advice from SCRS. In 2002, the Commission set the annual TAC, inclusive of dead discards, for the western Atlantic management area to 2,700 mt ww, effective beginning in 2003 (ICCAT Ref. 02-07). The current U.S. share of this TAC equals 1,496 mt ww inclusive of 25 mt ww for pelagic longline incidental catch in the Northeast Distant Statistical Reporting area and an allowance for dead discards of an additional 68 mt ww. If there are dead discards in excess of this allowance, they must be counted against the following year's quota. If there are fewer dead discards, then half of the underharvest may be added to the following year's quota while the other half is conserved. The recommendation also allowed four years to balance the eight percent tolerance for bluefin tuna under 115 cm (young school and school bluefin tuna).

*Bigeye Tuna*

ICCAT adopted a minimum size of 3.2 kg (7 lb) with a 15 percent tolerance level for undersized bigeye tuna in 1979. In 1995, noting the large increases in longline and purse seine catches of bigeye tuna and the large number of undersized fish, ICCAT urged countries to reduce catches below MSY and reduce catches of undersized fish. ICCAT also asked countries that had equatorial fisheries catching undersized fish to place observers on the vessels and allow SCRS to study the data. In 1997, ICCAT issued two resolutions to limit the catch of larger vessels in the Atlantic and the catch of countries that caught more than an average of 200 mt ww between 1992 and 1996 and to collect information on the larger vessels in the fleet (those greater than 80 GRT).

Large numbers of undersized fish are still harvested by the surface fleets operating near the equator. SCRS estimates that approximately 70 percent by number of bigeye tuna landed are smaller than the minimum size, well in excess of the 15 percent tolerance. Total Atlantic bigeye tuna catch has increased substantially since 1990. ICCAT has not recommended Atlantic-wide quotas for bigeye tuna. However, in 1998, ICCAT adopted two new management recommendations that are designed to limit effort in commercial fisheries for bigeye tuna throughout the Atlantic. ICCAT also adopted a resolution in 1998 that tasks SCRS with developing stock rebuilding scenarios for bigeye.

Purse seine fleets in the east Atlantic have developed a fishery that targets schools of tuna near artificial floating objects, also known as fish aggregating devices (FADs). This method of fishing has increased harvesting efficiency and contributed to excessive catch of undersized bigeye tuna. Favorable oceanographic conditions as well as the extensive use of sonar and deeper nets have also contributed to increased bigeye tuna harvest in recent years. In 1998, ICCAT established a mandatory time/area closure for purse seiners using fish aggregating devices in equatorial waters.

*Albacore Tuna*

Although albacore tuna harvests in the north Atlantic have declined since 1970, catch and effort in newer surface fisheries have increased since 1987. In 1997, SCRS determined that North Atlantic albacore tuna was at or near a level of full exploitation. In 1998, ICCAT adopted a recommendation to limit fishing capacity to the number of vessels in the directed albacore tuna fishery during the years of 1993 to 1995 and for countries to submit a list of vessels fishing for northern albacore. In 2003, ICCAT recommended a TAC of 34,500 mt ww for 2004, 2005, and 2006, of which the United States is allocated 607 mt ww per year.

ICCAT began managing southern Albacore when, in 1994, the SCRS found that catches of southern Albacore exceeded MSY. At this time, ICCAT recommended that countries limit the catch to 90 percent of previous levels. In 1996, ICCAT recommended a 22,000 mt ww quota for all countries fishing below 5º N latitude with the goal of achieving MSY by 2005. In 1998, this TAC was increased to 28,200 mt ww. In 2003, SCRS determined that southern albacore is not overexploited at current fishing levels. Thus, SCRS recommended that the TAC be 29,200 mt ww.

*Yellowfin Tuna*

Since the early 1970s, ICCAT has expressed concern over the high proportion of juvenile yellowfin tuna that are landed. In 1972, ICCAT passed a recommendation that prohibited the landing of yellowfin tuna less than 3.2 kg (7 lb). This recommendation also included an allowed 15 percent tolerance level on this minimum size. In 1995, an estimated 50 percent by number of yellowfin tuna landed were less than the minimum size. As in the bigeye tuna fisheries, these high catches of juveniles are largely a result of the use of FADs.

Atlantic yellowfin tuna landings reached a record high in 1990, primarily due to increased landings in the east Atlantic. Since 1990, catches across the Atlantic have declined somewhat and then remained stable. In 1993, ICCAT recommended that there be no increase in the level of effective fishing effort over 1992 levels.

*Skipjack Tuna*

The stock structure of Atlantic skipjack tuna is uncertain; separate management units are maintained in the eastern and western Atlantic. Skipjack tuna fisheries have changed significantly since 1991, with the introduction of fishing on floating objects and the expansion of the purse seine fishery towards the western Atlantic and closer to the equator. SCRS has noted that additional research on skipjack tuna is needed. At this time, there are no ICCAT recommendations or resolutions specific to skipjack tunas.

*All Tunas*

In April 1999, NMFS published the Final Fishery Management Plan for Atlantic Tunas, Swordfish, and Sharks (1999 FMP). This was the first FMP for Atlantic tunas. Some of the specific tuna management measures included:

- Prohibition of pelagic driftnets for tunas;
- Implementation of the BFT ICCAT Rebuilding Program;
- Establishment of category-specific percent BFT quota allocations;
- Implementation of a Cap on the Purse Seine category of 250 mt ww for BFT (later rescinded);
- Time/area closure in Mid-Atlantic to reduce bluefin tuna dead discards;
- Establishment of the foundation for developing an international 10-year rebuilding program for bigeye tuna;
- Establishment of a recreational retention limit of three yellowfin tuna per person per day; and
- Establishment a fishing year of June 1 to the following May 31.

### 3.1.1.2 Pre-1999 Atlantic Swordfish Fishery and Management

Unless otherwise specified, the following paragraphs regarding the early history of the swordfish fishery summarize information found in the Source Document to the 1985 Atlantic Swordfish Fishery Management Plan (SAFMC, 1985a). The summary of more recent history is a combination of information from the 1999 Fishery Management Plan for Atlantic Tunas, Swordfish, and Sharks and various ICCAT recommendations.

The recreational fishery for swordfish has existed since the 1920s when the fish were taken mainly by handline trailing a baited hook or occasionally by rod and reel or harpoon. This early fishery was located from Massachusetts to New York and, because it relied on locating the fish and enticing it to strike, occurred mainly during the day. Occasionally, an angler fishing for billfish in the Mid-Atlantic Bight would catch a swordfish.

In the 1970s, a recreational rod and reel fishery developed in Florida. This fishery borrowed techniques from longline fishermen and drifted the bait below the surface at night. Prior to the development of this fishery, fewer than 2,000 swordfish were estimated caught by all recreational fishermen over time in aggregate. In 1976, approximately 25 – 30 swordfish were taken off of Florida by rod and reel. By 1977, approximately 400 to 500 swordfish were taken. In 1978, swordfish tournaments were held in Florida, South Carolina, and New Jersey (the first ones ever for South Carolina and New Jersey) using this new technique. Due to a loss of interest by anglers and a relatively poor fishing year in 1979, there was a decrease in recreational effort in the early 1980s. In 1981 and 1982, only 86 and 53 swordfish were reported captured.

The commercial fishery began as a harpoon fishery between New York and Canada. In the 1960s, longline gear was introduced. This new gear expanded the range of the fishery down to the Gulf of Mexico and dramatically increased the amount of fish caught from approximately 2,800 mt ww in 1960 to 8,800 mt ww in 1963. Landings stabilized in the 1970s at around 5,000 mt ww.

In 1971, the U.S. Food and Drug Administration prohibited the sale of swordfish with more than 0.5 parts per million (ppm) tissue mercury content, leading to decreased landings of swordfish worldwide. In 1978, the permissible level of mercury was raised to 1.0 ppm, which rejuvenated the commercial fishery and landings increased as a result.

In the early years, there were essentially four primary components to the commercial swordfish fleet. There were approximately 25 vessels that used harpoons and spotter aircraft to catch swordfish in northern waters during the summer months. These vessels also participated in other fisheries because of the seasonal nature of the fishery. A mobile New England pelagic longline vessel component was comprised of vessels greater than 50 feet in length, and fished the Florida Straits primarily in winter and spring. Florida longline vessels, approximately 35 – 50 feet in length, fished mainly between Miami and Cape Canaveral and on the west coast of Florida. There were also Cuban-American vessels, usually between 25 to 40 feet in length, which fished between Key West and Miami. The harpoon fishery usually took female swordfish greater than 200 lb. The longline fleet usually took a mixture of male and female fish weighing between 10 and 300 lb.

By the early 1980s, the early styles of longline gear had been replaced by monofilament style gear. Additionally, the components of the fishery had changed. The larger New England vessels were still highly mobile and were now fishing from the Gulf of Mexico to the Florida Keys. The smaller Florida vessels became more mobile and began expanding into the Carolinas and the Mid-Atlantic area. Smaller vessels began to operate up and down the coast and even ventured into the edge of the Grand Banks. Many of these fishermen were either part-time swordfish fishermen who supplemented their income with charterboat fishing or full-time commercial fishermen who also fished for snappers, groupers, tilefish, and tunas.

From the late 1970s until the Atlantic swordfish FMP was approved in 1985, Federal management of swordfish was accomplished through the Preliminary Fishery Management Plan for Atlantic Billfishes and Sharks. This Preliminary FMP (43 FR 3818, January 27, 1978) was prepared by the Department of Commerce and established a number of requirements for foreign vessels fishing within the Atlantic fishery conservation zone (see section 1.1.2 for additional detail on the Preliminary FMP). Starting in June 1984, all vessels intending to catch swordfish by methods other than rod and reel were required to obtain a permit from NMFS Southeast Regional Office. By January 1985, 340 permit applications had been received (SAFMC, 1985b).

The Atlantic Swordfish FMP (February 1985) was prepared by the South Atlantic Fishery Management Council (SAFMC) in cooperation with the Caribbean Fishery Management Council (CFMC), the Gulf of Mexico Fishery Management Council (GMFMC), the Mid-Atlantic Fishery Management Council (MAFMC), and the New England Fishery Management Council (NEFMC). The final rule implementing the FMP published on August 22, 1985 (50 FR 33952; correction notice 50 FR 35563, September 3, 1985). This plan separated the swordfish fishery from the billfish fishery because, by this time, virtually all swordfish were taken commercially with longline or harpoon gear, while the majority of billfish were taken recreationally with rod and reel. However, it should be noted that there was a rapidly expanding market for marlin with increasing commercial landings from the late 1970s until the implementation of the Atlantic Billfish Fishery Management Plan in 1988. In the mid-1980s, Atlantic swordfish were considered to be in or near a state of growth overfishing.[1] The plan specified the following five management objectives (SAFMC, 1985b):

1. Maintain high landings in the form of the larger fish that are preferred in the market by controlling (reducing) the harvest of smaller swordfish.
2. Prevent or reduce growth overfishing to create a buffer against possible recruitment overfishing. This was to be done by maintaining a sufficient number of larger fish by controlling the harvest of smaller fish.
3. Obtain scientific information to continually monitor and refine the management of the swordfish fishery by an onboard technician program on a sample number of commercial boats.
4. Monitor and mitigate user group conflicts using the onboard technician program.

[1] Growth overfishing occurs when excessive numbers of small fish are harvested from a stock, thereby preventing growth to the size at which the maximum yield-per-recruit would be obtained from the stock.

5. Minimize the impacts of foreign fishing on the domestic U.S. swordfish fishery by minimizing the swordfish bycatch of foreign longliners and squid trawls consistent with the requirement to allow opportunities to harvest tuna or catch squid under a Governing International Fisheries Agreement.

Some of the management measures implemented in the Swordfish FMP were: variable season closures to control landings of small swordfish; requiring all commercially-caught swordfish to be landed whole or as carcasses; gear restrictions for closed areas; restrictions to foreign fishing for tuna longliners and squid trawlers; commercial permit requirement; observer or technician requirements; and reporting requirements for vessels in Puerto Rico or the U.S. Virgin Islands. In September 1986, NMFS published a notice stating that the variable season closures would not be implemented (51 FR 31151, September 2, 1986). In August 1990, a final rule published requiring mandatory dealer reporting (55 FR 35643, August 31, 1990).

In November 1990, ICCAT adopted its first Atlantic swordfish recommendation. This recommendation required members to reduce fishing mortality on fish weighing more than 25 kg (55 lb) by 15 percent from 1988 fishing levels and to prohibit the landing of swordfish less than 25 kg with a 15 percent tolerance level. NMFS implemented this recommendation with an emergency rule (56 FR 26934, June 12, 1991) and later a final rule (56 FR 65007; December 13, 1991).

At its 1994 meeting, ICCAT established specific TAC levels for nations fishing for both North and South Atlantic swordfish stocks (the United States was allocated 3,970 mt ww and 3,500 mt ww for 1995 and 1996, respectively). At the 1995 meeting, ICCAT adopted recommendations that allowed nations to maintain the existing minimum size for swordfish with a 15 percent tolerance of smaller fish or alternatively to abide by a smaller minimum size (119 cm or equivalent weight) with no tolerance. ICCAT also adjusted the percentages each country received of the total allowable catch levels for North Atlantic swordfish, and established measures to account for over- and underharvests. Under the 1995 recommendation, the United States receives 29 percent of the available total allowable quota. From 1995 to 1999, NMFS modified the existing U.S. quotas for Atlantic swordfish based on these recommendations and a 1996 recommendation that established the TAC at 11,300, 11,000, and 10,700 mt ww in 1997, 1998, and 1999, respectively (the United States' allocation was 3,277, 3,190, and 3,103 mt ww in 1997, 1998, and 1999, respectively).

In 1999, NMFS implemented a number of regulations that affected swordfish fishermen, including a prohibition on the use of driftnets in the swordfish fishery, and regulations to aid in tracking swordfish trade including dealer permitting and reporting for all swordfish importers, a documentation scheme that indicated the country of origin and flag of the vessel, and a prohibition on importing swordfish less than the minimum size. These regulations were codified in the first quarter of 1999. In April 1999, NMFS published the 1999 FMP. This FMP replaced the 1985 Swordfish FMP that had been drafted by the Fishery Management Councils. The 1999 FMP maintained a number of the management measures from the previous FMP including reporting requirements, annual quotas, authorized gear, and the minimum size. However, the 1999 FMP also called for the United States to negotiate an international rebuilding plan, required that recreational landings be counted against the U.S. portion of the ICCAT-established TAC, and implemented a limited access program for commercial vessel permits.

In November 1999, ICCAT established a 10-year rebuilding program for Atlantic swordfish. This rebuilding program reduced the North Atlantic TAC (10,600, 10,500, and 10,400 mt ww for the years 2000, 2001 and 2002, respectively; 2951 mt ww for the United States in all years), established a dead discard allowance (400 , 300, and 200 mt ww in 2000, 2001, and 2002, respectively; 80 percent to the United States; phased out by 2004; the TAC minus the allowance for dead discards is the amount that could be retained) , restated the need for data reporting, and maintained the existing minimum size limits. In 2002, noting the improvement on the stock, ICCAT increased the overall TAC slightly while simultaneously reemphasizing the need to protect juvenile swordfish.

#### 3.1.1.3 Pre-1999 Atlantic Shark Fisheries and Management

Unless otherwise specified, the main sources of the following history are the 1993 Atlantic Shark Fishery Management Plan and the 1999 FMP for Atlantic Tunas, Swordfish, and Sharks.

Recreational fishing for Atlantic sharks occurs in Federal and state waters from New England to the Gulf of Mexico and Caribbean Sea. In the past, sharks were often called “the poor man’s marlin.” Recreational shark fishing with rod and reel is now a popular sport at all social and economic levels, largely because of accessibility to the resource. Sharks can be caught virtually anywhere in salt water, with even large specimens available in the nearshore area to surf anglers or small boaters. Most recreational shark fishing takes place from small to medium-size vessels. Mako, white, and large pelagic sharks are generally accessible only to those aboard ocean-going vessels. Recreational shark fisheries are exploited primarily by private vessels and charter/headboats although there are some shore-based fishermen active in the Florida Keys.

The commercial shark fishery has been sporadic in nature. In the early 1900s, a Pacific shark fishery supplied limited demands for fresh shark fillets and fish meal as well as a more substantial market for dried fins of soupfin sharks. In 1937, the price of soupfin shark liver skyrocketed when it was discovered to be the richest source of vitamin A available in commercial quantities. A shark fishery in the Caribbean Sea, off the coast of Florida, and in the Gulf of Mexico developed in response to this demand (Wagner, 1966). At this time, shark fishing gear included gillnets, hook and line, anchored bottom longlines, floating longlines, and benthic lines for deepwater fishing. These gear types are slightly different than the gears used today and are fully described in Wagner (1966). By 1950, the availability of synthetic vitamin A caused most shark fisheries to be abandoned (Wagner, 1966).

A small fishery for porbeagle existed in the early 1960s off the U.S. Atlantic coast involving Norwegian fishermen. Between the World Wars, Norwegians and Danes had pioneered fishing for porbeagles in the North Sea and in the region of the Shetland, Orkney, and the Faroe Islands. In the late 1940s, these fishermen caught from 1,360 to 2,720 mt yearly, with lesser amounts in the early 1950s (Rae, 1962). The subsequent scarcity of porbeagles in their fishing area forced the Norwegians to explore other grounds, and around 1960, they began fishing the Newfoundland Banks and the waters east of New York. Between 1961 and 1964, their catch increased from 1,800 to 9,300 mt, then declined to 200 mt (Casey *et al*., 1978).

The U.S. Atlantic shark fishery developed rapidly in the late 1970s due to increased demand for their meat, fins, and cartilage. At the time, sharks were perceived to be underutilized as a fishery resource. The high commercial value of shark fins led to the controversial practice of finning, or removing the valuable fins from sharks and discarding the carcass. Growing demand for shark products encouraged expansion of the commercial fishery throughout the late 1970s and the 1980s. Tuna and swordfish vessels began to retain a greater proportion of their shark incidental catch, and some directed fishery effort expanded as well. The Secretary of Commerce published the Preliminary Fishery Management Plan for Atlantic Billfish and Sharks in 1978, which noted, among other things, the need for international management regarding sharks. As catches accelerated through the 1980s, shark stocks suffered a precipitous decline. Peak commercial landings of large coastal and pelagic sharks were reported in 1989.

In 1989, the five Atlantic Fishery Management Councils asked the Secretary of Commerce to develop a Shark FMP. The Councils were concerned about the late maturity and low fecundity of sharks, the increase in fishing mortality, and the possibility of the resource being overfished. The Councils requested that the FMP cap commercial fishing effort, establish a recreational bag limit, prohibit "finning," and begin a data collection system.

In 1993, the Secretary of Commerce, through NMFS, implemented the FMP for Sharks of the Atlantic Ocean. The management measures in the 1993 FMP included:

- Establishing a fishery management unit (FMU) consisting of 39 frequently caught species of Atlantic sharks, separated into three groups for assessment and regulatory purposes (Large Coastal Sharks (LCS), Small Coastal Sharks (SCS), and pelagic sharks);
- Establishing calendar year commercial quotas for the LCS and pelagic sharks and dividing the annual quota into two equal half-year quotas that apply to the following two fishing periods – January 1 through June 30 and July 1 through December 31;
- Establishing a recreational trip limit of four sharks per vessel for LCS or pelagic shark species groups and a daily bag limit of five sharks per person for sharks in the SCS species group;
- Requiring that all sharks not taken as part of a commercial or recreational fishery be released uninjured;
- Establishing a framework procedure for adjusting commercial quotas, recreational bag limits, species size limits, management unit, fishing year, species groups, estimates of maximum sustainable yield, and permitting and reporting requirements;
- Prohibiting finning by requiring that the ratio between wet fins/dressed carcass weight not exceed five percent;
- Prohibiting the sale by recreational fishermen of sharks or shark products caught in the Economic Exclusive Zone (EEZ);

- Requiring annual commercial permits for fishermen who harvest and sell shark (meat products and fins);
- Establishing a permit eligibility requirement that the owner or operator (including charter vessel and headboat owners/operators who intend to sell their catch) must show proof that at least 50 percent of earned income has been derived from the sale of the fish or fish products or charter vessel and headboat operations or at least $20,000 from the sale of fish during one of three years preceding the permit request;
- Requiring trip reports by permitted fishermen and persons conducting shark tournaments and requiring fishermen to provide information to NMFS under the Trip Interview Program; and,
- Requiring NMFS observers on selected shark fishing vessels to document mortality of marine mammals and endangered species.

At that time, NMFS identified LCS as overfished and pelagic and SCS as fully fished. The quotas were 2,436 mt dressed weight (dw) for LCS and 580 mt dw for pelagic sharks. No quota was established for SCS. Under the rebuilding plan established in the 1993 FMP, the LCS quota was expected to increase every year up to the maximum sustainable yield estimated in the 1992 stock assessment, which was 3,787 mt dw.

A number of difficulties arose in the initial year of implementation of the Shark FMP that resulted in a short season and low ex-vessel prices. To address these problems, a commercial trip limit of 4,000 lb. for permitted vessels for LCS was implemented on December 28, 1993 (58 FR 68556), and a control date for the Atlantic shark fishery was established on February 22, 1994 (59 FR 8457). A final rule to implement additional measures authorized by the FMP published on October 18, 1994 (59 FR 52453), which:

- Clarified operation of vessels with a Federal commercial permit;
- Established the fishing year;
- Consolidated the regulations for drift gillnets;
- Required dealers to obtain a permit to purchase sharks;
- Required dealer reports;
- Established recreational bag limits;
- Established quotas for commercial landings; and
- Provided for commercial fishery closures when quotas were reached.

In 1994, under the rebuilding plan implemented in the 1993 Shark FMP, the LCS quota was increased to 2,570 mt dw. Additionally, a new stock assessment was completed in March 1994 that indicated rebuilding LCS could take as long as 30 years and suggested a more cautious approach for pelagic sharks and SCS. A final rule that capped quotas for LCS and pelagic sharks at the 1994 levels was published on May 2, 1995 (60 FR 21468).

In June 1996, NMFS convened another stock assessment to examine the status of LCS stocks. The 1996 stock assessment found no clear evidence that LCS stocks were rebuilding and concluded that "[a]nalyses indicate that recovery is more likely to occur with reductions in effective fishing mortality rate of 50 [percent] or more." In response to these results, in 1997, NMFS reduced the LCS commercial quota by 50 percent to 1,285 mt dw and the recreational retention limit to two LCS, SCS, and pelagic sharks combined per trip with an additional allowance of two Atlantic sharpnose sharks per person per trip (62 FR 16648, April 2, 1997). In this same rule, NMFS established an annual commercial quota for SCS of 1,760 mt dw and prohibited possession of five species. As a result of litigation, NMFS prepared additional economic analyses on the 1997 LCS quotas and was allowed to maintain those quotas during resolution of the case.

In June 1998, NMFS held another LCS stock assessment. The 1998 stock assessment found that LCS were overfished and would not rebuild under 1997 harvest levels. Based in part on the results of the 1998 stock assessment, in April 1999, NMFS published the 1999 FMP which included numerous measures to rebuild or prevent overfishing of Atlantic sharks in commercial and recreational fisheries. The 1999 FMP replaced the 1993 Atlantic Shark FMP. Management measures related to sharks that changed in the 1999 FMP included:

- Reducing commercial LCS and SCS quotas;
- Establishing ridgeback and non-ridgeback categories of LCS;
- Implementing a commercial minimum size for ridgeback LCS;
- Establishing blue shark, porbeagle shark, and other pelagic shark subgroups of the pelagic sharks and establishing a commercial quota for each subgroup;
- Reducing recreational retention limits for all sharks;
- Establishing a recreational minimum size for all sharks except Atlantic sharpnose;
- Expanding the list of prohibited shark species to 19 species;
- Implementing limited access in commercial fisheries;
- Establishing a shark public display quota;
- Establishing new procedures for counting dead discards and state landings of sharks after Federal fishing season closures against Federal quotas; and
- Establishing season-specific over- and underharvest adjustment procedures.

The implementing regulations were published on May 28, 1999 (64 FR 29090). However, in 1999, a court enjoined implementation of the 1999 regulations, as they related to the ongoing litigation on the 1997 quotas. Further history of this litigation and shark management is provided under Section 3.1.1.7 below. A year later, on June 12, 2000, the court issued an order clarifying that NMFS could proceed with implementation and enforcement of the 1999 prohibited species provisions (64 FR 29090, May 28, 1999).

#### 3.1.1.4 1999 Fishery Management Plan for Atlantic Tunas, Swordfish, & Sharks

As described, the 1999 FMP replaced the existing Atlantic Shark and Atlantic Swordfish FMPs, and established the first FMP for Atlantic tunas. Before the 1999 FMP, Atlantic tunas were managed only under the ATCA; after the 1999 FMP, Atlantic tunas were managed under both the Magnuson-Stevens Act and ATCA.

NMFS began working on the 1999 FMP shortly after the U.S. Congress reauthorized the Magnuson-Stevens Act in 1996. The 1996 Magnuson-Stevens Act amendments added new fishery management requirements including requiring NMFS to halt overfishing; rebuild overfished fisheries; minimize bycatch and bycatch mortality, to the extent practicable; and identify and protect essential fish habitat (EFH). These provisions were coupled with the recognition that the management of HMS requires international cooperation and that rebuilding programs must reflect traditional participation in the fisheries by U.S. fishermen, relative to foreign fleets.

Development of the 1999 HMS FMP began in September 1997 with the formation of the HMS Advisory Panel (AP). The HMS AP was established under a requirement of the Magnuson-Stevens Act, and is composed of representatives of the commercial and recreational fishing communities, conservation and academic organizations, the five regional fishery management councils involved in Atlantic HMS management, the Atlantic and Gulf coastal states, and the U.S. ICCAT Advisory Committee. The HMS AP met seven times during development of the 1999 FMP, including once during the public comment period on the draft FMP, and provided extensive comment and advice to NMFS.

In October 1997, NMFS prepared and distributed a scoping document to serve as the starting point for consideration of issues for the 1999 FMP. The scoping document described major issues in the fishery, legal requirements for management, and potential management measures that could be considered for adoption in the FMP and solicited public comment on these issues. The scoping document was the subject of 21 public hearings that were held in October and November 1997 throughout the management area. The scoping meetings allowed NMFS to gather information from participants in the fisheries, and provided a mechanism by which the public could provide input to NMFS early in the FMP development process.

In October 1998, NMFS announced in the Federal Register the availability of the draft FMP. The comment period on the draft FMP lasted from October 25, 1998, to March 12, 1999. The proposed rule that accompanied the draft FMP was published in the Federal Register on January 20, 1999. The supplemental part that related to the bluefin tuna rebuilding program published in the Federal Register on February 25, 1999. The comment period on the proposed rule and its supplement also went until March 12, 1999. Subsequent to the release of the proposed rule, NMFS held 27 public hearings in communities from Texas to Maine and the Caribbean. During the comment period, NMFS received several thousand comments from commercial and recreational fishermen, scientists, conservationists, and concerned individuals. An HMS AP meeting was held toward the end of the comment period to allow HMS AP members to view most of the comments NMFS had received on the draft FMP and accompanying proposed rule.

The 1999 FMP incorporated all existing management measures for Atlantic tuna and north Atlantic swordfish that have been issued previously under the authority of the ATCA. It also incorporated all existing management measures for north Atlantic swordfish and Atlantic sharks that had previously been issued under the authority of the Magnuson-Stevens Act. Southern Atlantic swordfish and southern Atlantic albacore tuna continue to be managed only under ATCA. In November 2004, ICCAT adopted its first recommendation for Atlantic sharks.

Some of the non-species specific management measures of the 1999 FMP included vessel monitoring systems for all pelagic longline vessels; gear and vessel marking requirements; moving pelagic longline gear after an interaction with a protected species; a requirement for charter/headboats to obtain an annual vessel permit; tournament registration for all HMS tournaments; time limits on completing a vessel logbook; and expanded observer coverage. The 1999 FMP also established the threshold levels to determine if a stock is overfished, if overfishing is occurring, or if the stock is rebuilt. Finally, the 1999 FMP identified essential fish habitat (EFH) for all Atlantic tunas, swordfish, and sharks. As part of the 1999 FMP, the regulations for all Atlantic HMS, including billfish, were consolidated into one part of the Code of Federal Regulations, 50 CFR part 635. Before then, each species had its own part. This often led to confusion and, in some cases, conflicting regulations.

#### 3.1.1.5 Post 1999 FMP

After issuance of the 1999 FMP, a number of constituents (environmental, commercial fishermen, and recreational fishermen) sued the NMFS (the Agency) over aspects of the plan, including the BFT rebuilding program, the use of vessel monitoring systems in the pelagic longline fleet, the time/area closure for the pelagic longline fleet, the pelagic shark quotas, the shark and yellowfin tuna recreational retention limits, the large and small coastal shark quotas, and the bluefin tuna purse seine allocation. The Agency received favorable court rulings, upholding its actions, in most of these cases, and resolved some matters via settlement agreements. All of the briefings and court orders are a matter of the public record.

#### 3.1.1.6 Regulatory Amendments Relating to the Pelagic Longline Fishery

In the 1999 FMP, NMFS committed to implement a closed area that would effectively protect small swordfish. NMFS began to work towards this goal shortly after the publication of the 1999 FMP. After the publication of the 1999 FMP, NMFS was sued by environmentalists who felt, among other things, that the Agency had not done enough to reduce bycatch in HMS fisheries. As a result, NMFS expanded the goal of the rule to reduce all bycatch and bycatch mortality, to the extent practicable, in the HMS pelagic longline fishery. The following objectives were developed to guide agency action for this goal:

- Maximize the reduction in finfish bycatch;
- Minimize the reduction in the target catch of swordfish and other species;
- Consider impacts on the incidental catch of other species to minimize or reduce incidental catch levels; and
- Optimize survival of bycatch and incidental catch species.

NMFS published the final rule implementing the first regulatory amendment to the 1999 FMP on August 1, 2000 (65 FR 47214), which closed three large areas (DeSoto Canyon, Florida East Coast, and Charleston Bump) and prohibited the use of live bait in the Gulf of Mexico

During the course of this rulemaking, the pelagic longline fleet exceeded the incidental take statement for sea turtles established during the Endangered Species Act (ESA) Section 7 Consultation for the 1999 FMP. That, combined with new information on sea turtles and the uncertainty regarding what the closures would mean for sea turtles, resulted in a new Biological Opinion (BiOp) (June 30, 2000) that concluded that the continuation of the pelagic longline fishery would jeopardize the continued existence of leatherback and loggerhead sea turtles. As a result of the jeopardy finding, NMFS needed to implement certain measures to reduce sea turtle bycatch in the pelagic longline fishery.

Shortly after this conclusion, NMFS decided that further analyses of observer data and additional population modeling of loggerhead sea turtles were needed to determine more precisely the impact of the pelagic longline fishery on turtles. Because of this, NMFS reinitiated consultation on the HMS fisheries on September 7, 2000. In the interim, NMFS implemented emergency regulations, based on historical data on sea turtle interactions, to reduce the short-term effects of the pelagic longline fishery on sea turtles. An emergency rule that closed a portion of the Northeast Distant Statistical Area (NED) and required dipnets and line clippers to be carried and used on pelagic longline vessels to aid in the release of any captured sea turtle published on October 13, 2000 (65 FR 60889).

NMFS issued a BiOp on June 8, 2001 (revised on June 14, 2001), that again concluded that the continued operation of the Atlantic pelagic longline fishery is likely to jeopardize the continued existence of loggerhead and leatherback sea turtles. Accordingly, the BiOp provided a reasonable and prudent alternative (RPA) to avoid jeopardy. This BiOp concluded no jeopardy for other HMS fisheries, but did require additional management measures to reduce sea turtle takes in these fisheries. The RPA included the following elements: closing the NED area effective July 15, 2001, and conducting a research experiment in this area to reduce sea turtle bycatch and bycatch mortality in the PLL fishery; requiring gangions to be placed no closer than twice the average gangion length from the suspending floatlines effective August 1, 2001; requiring gangion lengths to be 110 percent of the length of the floatline in sets of 100 meters or less in depth effective August 1, 2001; and, requiring the use of corrodible hooks effective August 1, 2001. Also, the BiOp included a term and condition for the incidental take statement that required NMFS to issue a regulation requiring that all vessels permitted for HMS fisheries, commercial and recreational, post the sea turtle guidelines for safe handling and release following longline interactions inside the wheelhouse by September 15, 2001. The requirement that all vessels permitted for HMS fisheries post sea turtle handling and release guidelines was modified to specify only bottom and pelagic longline vessels by an August 31, 2001, memorandum from the Office of Protected Resources.

On July 13, 2001, NMFS published an emergency rule (66 FR 36711) to implement several of the BiOp requirements. NMFS published an amendment to the emergency rule to incorporate the change in requirement for the handling and release guidelines that was published in the Federal Register on September 24, 2001 (66 FR 48812).

On July 9, 2002, NMFS published the final rule (67 FR 45393) implementing measures required under the June 14, 2001, BiOp on Atlantic HMS to reduce the incidental catch and post-release mortality of sea turtles and other protected species in HMS Fisheries, with the exception of the gangion placement measure. The rule implemented the NED closure, required the length of any gangion to be 10 percent longer than the length of any floatline if the total length of any gangion plus the total length of any floatline is less than 100 meters, and prohibited vessels from having hooks on board other than corrodible, non-stainless steel hooks. In the HMS shark gillnet fishery, both the observer and vessel operator must look for whales, the vessel operator must contact NMFS if a listed whale is taken and shark gillnet fishermen must conduct net checks every 0.5 to 2 hours to look for and remove any sea turtles or marine mammals from their gear. The final rule also required all HMS bottom and pelagic longline vessels to post sea turtle handling and release guidelines in the wheelhouse. NMFS did not implement the gangion placement requirement because it appeared to result in an unchanged number of interactions with loggerhead sea turtles and an apparent increase in interactions with leatherback sea turtles.

In 2001, 2002, and 2003, NMFS in conjunction with the fishing industry conducted an experiment in the NED to see if certain gear restrictions or requirements could reduce sea turtle captures and mortality. The results of this experiment indicated that certain gear types could reduce sea turtle interactions and mortality and that certain methods of handling and releasing turtles could further reduce mortality. For example, using 16/0 non-offset or 18/0 offset hooks of at least 10 degrees could reduce leatherback and loggerhead sea turtle interactions by approximately 50 and 0 percent, respectively. Using 18/0 hooks flat or offset up to 10 degrees could reduce leatherback and loggerhead sea turtle interactions by approximately 50 and 65 percent, respectively. NMFS is currently, in conjunction with the fishing industry, conducting additional experiments to verify these results throughout the fishery. Additionally, NMFS is working to export these results to other countries to reduce sea turtle interactions and mortality throughout the Atlantic and Pacific Oceans.

On November 28, 2003, based on the conclusion of this experiment and based on preliminary data that indicated that the Atlantic pelagic longline fishery may have exceeded the ITS in the June 14, 2001 BiOp, NMFS published a Notice of Intent (NOI) to prepare a Supplemental Environmental Impact Statement (SEIS) to assess the potential effects on the human environment of proposed alternatives and actions under a proposed rule to reduce sea turtle bycatch (68 FR 66783).

In January 2004, NMFS reinitiated consultation after receiving data that indicated the Atlantic pelagic longline fishery exceeded the incidental take statement for leatherback sea turtles in 2001 – 2002 and for loggerhead sea turtles in 2002. In the spring of 2004, NMFS released a proposed rule that would require fishermen to use certain hook and bait types and take other measures to reduce sea turtle takes and mortality. The resulting June 1, 2004, BiOp considered these measures and concluded that the pelagic longline fishery was not likely to jeopardize the continued existence of loggerhead sea turtles, but was still likely to jeopardize the continued existence of leatherback sea turtles. NMFS published a final rule implementing many gear and bait restrictions and requiring certain handling and release tools and methods on July 6, 2004 (69 FR 40734). NMFS also published an Advance Notice of Proposed Rulemaking to receive comments on how to further reduce sea turtle mortality (69 FR 49858, August 12, 2004), held several workshops to demonstrate sea turtle release equipment and techniques (69 FR 44513), and released revised sea turtle handling and release placards, protocols, and a video. The placards, protocols, and video are available in English, Spanish, and Vietnamese. NMFS continues to monitor the sea turtle takes in the pelagic longline fishery and may need to take further action if sea turtle takes do not remain below the levels specified in the June 2004 BiOp.

#### 3.1.1.7 Amendment 1 to the Fishery Management Plan for Atlantic Tunas, Swordfish, and Sharks

As noted under Section 3.1.1.3, in 1999, a court enjoined the Agency from implementing many of the shark-specific regulations in the 1999 FMP. In 2000, the injunction was lifted when a settlement agreement was entered to resolve the 1997 and 1999 lawsuits. The settlement agreement required, among other things, an independent (*i.e.*, non-NMFS) review of the 1998 LCS stock assessment. The settlement agreement did not address any regulations affecting the pelagic shark, prohibited species, or recreational shark fisheries. Once the injunction was lifted, on January 1, 2001, the pelagic shark quotas adopted in the 1999 HMS FMP were implemented (66 FR 55). Additionally, on March 6, 2001, NMFS published an emergency rule implementing the settlement agreement (66 FR 13441). This emergency rule expired on September 4, 2001, and established the LCS and SCS commercial quotas at 1997 levels.

In late 2001, the Agency received the results of the peer review of the 1998 LCS stock assessment. These peer reviews found that the 1998 LCS stock assessment was not the best available science for LCS. Taking into consideration the settlement agreement, the results of the peer reviews of the 1998 LCS stock assessment, current catch rates, and the best available scientific information (not including the 1998 stock assessment projections), NMFS implemented another emergency rule for the 2002 fishing year that suspended certain measures under the 1999 regulations pending completion of new LCS and SCS stock assessments and a peer review of the new LCS stock assessment (66 FR 67118, December 28, 2001; extended 67 FR 37354, May 29, 2002). Specifically, NMFS maintained the 1997 LCS commercial quota (1,285 mt dw), maintained the 1997 SCS commercial quota (1,760 mt dw), suspended the commercial ridgeback LCS minimum size, suspended counting dead discards and state landings after a Federal closure against the quota, and replaced season-specific quota accounting methods with subsequent-season quota accounting methods. That emergency rule expired on December 30, 2002.

On May 8, 2002, NMFS announced the availability of a SCS stock assessment (67 FR 30879). The Mote Marine Laboratory and the University of Florida provided NMFS with another SCS assessment in August 2002. Both of these stock assessments indicate that overfishing is occurring on finetooth sharks while the three other species in the SCS complex (Atlantic sharpnose, bonnethead, and blacknose) are not overfished and overfishing is not occurring. On October 17, 2002, NMFS announced the availability of the 2002 LCS stock assessment and the workshop meeting report (67 FR 64098). The results of this stock assessment indicate that the LCS complex is still overfished and overfishing is occurring. Additionally, the 2002 LCS stock assessment found that sandbar sharks are no longer overfished but that overfishing is still occurring and that blacktip sharks are rebuilt and overfishing is not occurring.

Based on the results of both the 2002 SCS and LCS stock assessments, NMFS implemented an emergency rule to ensure that the commercial management measures in place for the 2003 fishing year were based on the best available science (67 FR 78990, December 27, 2002; extended 68 FR 31987, May 29, 2003). Specifically, the emergency rule implemented the LCS ridgeback/non-ridgeback split, set the LCS and SCS quotas based on the results of stock assessments, suspended the commercial ridgeback LCS minimum size, and allowed both the season-specific quota adjustments and the counting of all mortality measures to go into place.

In December 2003, NMFS implemented the regulations in Amendment 1 to the Fishery Management Plan for Atlantic Tunas, Swordfish, and Sharks (68 FR 74746). These regulations were based on the 2002 small and large coastal shark stock assessments. Some of the measures taken in Amendment 1 included revising the rebuilding timeframe for LCS; re-aggregating the LCS complex; establishing a method of changing the quota based on maximum sustainable yield (MSY); updating some shark EFH identifications; modifying the quotas, seasons, and regions; adjusting the recreational bag limit; establishing criteria to add or remove species to the prohibited shark list; establishing gear restrictions to reduce bycatch and bycatch mortality; establishing a time/area closure off of North Carolina for bottom longline fishermen; and establishing VMS requirements for bottom longline and gillnet fishermen.

#### 3.1.1.8 Other Post-1999 FMP Regulations for Atlantic Tunas, Swordfish, and Sharks

Since the 1999 FMP, there have been a number of other regulatory actions in addition to the rules mentioned above. Below is a short list of some of these actions.

- <u>Removal of the bluefin tuna purse seine category cap</u>: In the 1999 FMP, NMFS finalized an alternative that would have capped the quota for vessels in the purse seine category at 250 mt ww. On November 1, 1999, NMFS published a final rule that removed the purse seine category quota cap (64 FR 58793). In that rule, the purse seine category was given 18.6 percent of the total landings quota available to the United States.

- <u>Change to bluefin tuna incidental category catch limits</u>: In May 2003 (68 FR 32414), NMFS modified the target catch requirements for vessels participating in the Atlantic Tunas Longline category such that pelagic longline vessels would have to land 2,000 lb. of other fish in order to land one bluefin tuna on a trip, 6,000 lb. of other fish in order to land two bluefin tuna on a trip, and 30,000 lb. of other fish to land three bluefin tuna. The rule was designed to reduce the discards of bluefin tuna. This change in the target catch requirements applies to all fishing areas. This rule also maintained separate quotas for the seasonal fisheries, adjusted the Longline category North/South division line to 31°00’ N. latitude and adjust the Longline category subquotas to allocate 60 percent to the southern area and 40 percent to the northern area.
- <u>Bluefin tuna amendment</u>: On December 24 , 2003 (68 FR 74504), NMFS published a final rule that changed the opening date of the Purse seine category, established closure dates of the Harpoon and General categories, and set size tolerances of large medium BFT for the Purse seine and Harpoon categories.

- Recreational permits and reporting requirements: On December 18, 2002 (67 FR 77434), NMFS published a final rule requiring all vessel owners fishing recreationally (*i.e.*, no sale) for Atlantic HMS, including billfish, to obtain an Atlantic HMS recreational angling category permit. On January 7, 2003 (68 FR 711), a final rule establishing a mandatory reporting system for all non-tournament recreational landings of Atlantic marlins, sailfish, and swordfish was published. These requirements became effective in March 2003.
- International trade permit: On November 17, 2004, NMFS published a final rule that implements the recommendations of ICCAT and the Inter-American Tropical Tuna Commission (IATTC) for bluefin tuna, swordfish, and bigeye tuna (69 FR 67268). The rule requires all importers and exporters, regardless of ocean basin, of bluefin tuna, swordfish, and bigeye tuna to obtain an HMS International Trade Permit on an annual basis, report imports and exports on species-specific statistical documents and re-export certificates, and submit biweekly activity reports to NMFS. The rule is effective on July 1, 2005.
- Import restrictions: Due to compliance concerns, ICCAT has recommended numerous import restrictions on countries that have not shown that they are complying with ICCAT recommendations. Over the years, the countries and species that have import restrictions placed on them have changed. As of July 2, 2005, bigeye tuna from Bolivia or Georgia will not be allowed to be imported into the United States (May 17, 2005, 70 FR 28218). Additionally, ICCAT established "positive" and "negative" lists. These lists outline all the vessels that have permits and do not conduct IUU fishing (positive list) and those vessels that are not permitted and have conducted IUU fishing in the past (negative list). Fish that were caught on vessels that are not on the positive list or that are on the negative list cannot be imported into the United States (December 6, 2004, 69 FR 70396).
- Quota adjustments: Based on various ICCAT recommendations, NMFS has adjusted the quotas for North and South Atlantic swordfish (69 FR 68090, November 23, 2004) and Atlantic bluefin tuna.
- 
- National Plan of Action for the Conservation and Management Of Sharks: On February 15, 2001, NMFS released the final National Plan of Action (NPOA) for the Conservation and Management of Sharks (66 FR 10484). The NPOA was developed pursuant to the endorsement of the International Plan of Action (IPOA) by the United Nations' Food and Agriculture Organization Committee on Fisheries Ministerial Meeting in February 1999. The overall objective of the IPOA is to ensure conservation and management of sharks and their long-term sustainable use. The final NPOA, consistent with the Magnuson-Stevens Act, requires NMFS and the Regional Fishery Management Councils to undertake extensive data collection, analysis, and management measures in order to ensure the long-term sustainability of U.S. shark fisheries. The NPOA also encourages Interstate Marine Fisheries Commissions and State agencies to initiate or expand current data collection, analysis, and management measures and to implement regulations consistent with federal regulations, as needed. For additional information on the U.S. NPOA and its implementation, see http://www.nmfs.noaa.gov.
- Shark Finning Prohibition Act: On December 21, 2000, President Clinton signed the Shark Finning Prohibition Act into law (Public Law 106-557). This amended the

Magnuson-Stevens Fishery Conservation and Management Act to prohibit any person under U.S. jurisdiction from (i) engaging in the finning of sharks; (ii) possessing shark fins aboard a fishing vessel without the corresponding carcass; and (iii) landing shark fins without the corresponding carcass. NMFS published final regulations on February 11, 2002 (67 FR 6194). These regulations prohibit the finning of sharks, possession of sharks without the corresponding carcasses, and landings of shark carcasses without the corresponding carcasses in U.S. fisheries in the exclusive economic zone and on the high seas.

Other regulatory actions that have been taken including opening and closing of fisheries and adjustments to quota allocations. All of these actions are not listed here but can be found by searching the Federal Register webpage at http://www.gpoaccess.gov/fr/index.html or by reviewing the annual HMS SAFE reports (http://www.nmfs.noaa.gov/sfa/hms).

### 3.1.2 History of Atlantic Billfish Fishery Management

Atlantic billfish managed by NMFS are Atlantic blue marlin (*Makaira nigricans*), white marlin (*Tetrapturus albidus*), sailfish (*Istiophorus platypterus*), and longbill spearfish *(Tetrapturus pfluegeri)*. Atlantic billfish management strategies have been guided by international and domestic considerations and mechanisms since the 1970s.

#### 3.1.2.1 Preliminary Fishery Management Plan (PMP) for Atlantic Billfish and Sharks

Domestic management of Atlantic billfish resources has been developed, modified, and implemented in three primary stages and through a series of other rulemakings. In January 1978, NMFS published the Preliminary Fishery Management Plan (PMP) for Atlantic Billfish and Sharks (43 FR 3818), which was supported by an EIS (42 FR 57716). This PMP was a Secretarial effort. The management measures contained in the plan were designed to:

1. minimize conflict between domestic and foreign users of billfish and shark resources;
2. encourage development of an international management regime; and
3. maintain availability of billfishes and sharks to the expanding U.S. fisheries.

Primary management measures in the Atlantic Billfish and Shark PMP included:

- Mandatory data reporting requirements for foreign vessels;
- A prohibition on the foreign commercial retention of all billfishes caught within the Fishery Conservation Zone (FCZ) of the United States and stipulated release in a manner that will maximize the probability of survival;
- A hard cap on the catch of sharks by foreign vessels, which when achieved would prohibit further landings of sharks by foreign vessels;
- Permit requirements for foreign vessels to fish in the FCZ of the United States;
- Radio checks by foreign vessels upon entering and leaving the FCZ;

- Boarding and inspection privileges for U.S. observers; and
- Prohibition on intentional discarding of fishing gears by foreign fishing vessels within the FCZ that may pose environmental or navigational hazards.

#### 3.1.2.2 The Fishery Management Plan for the Atlantic Billfishes

Building upon the PMP for Atlantic Billfish and Sharks was the Fishery Management Plan for the Atlantic Billfishes (53 FR 21501). This plan was jointly developed by five Atlantic regional councils (Caribbean, Gulf, South Atlantic, Mid-Atlantic, New England) and implemented in October 1988 (53 FR 37765). The 1988 FMP defined the Atlantic billfish management unit to include sailfish from the western Atlantic Ocean, white marlin and blue marlin from the North Atlantic Ocean, and longbill spearfish from the entire Atlantic Ocean; described objectives for the Atlantic billfish fishery; and established management measures to achieve those objectives. The objectives identified in the Billfish FMP were to:

1. Maintain the highest availability of billfishes to the U.S. recreational fishery by implementing conservation measures that will reduce fishing mortality;
2. Optimize the social and economic benefits to the nation by reserving the billfish resource for its traditional use, which in the continental United States is almost entirely a recreational fishery; and
3. Increase understanding of the condition of billfish stocks and the billfish fishery.

The primary management measures adopted to achieve the stated objectives of the 1988 Billfish FMP included:

- Defining OY in qualitative terms;
- A prohibition on the sale of Atlantic billfish, with an exemption for small-scale handline (artisanal) fishery in Puerto Rico;
- Establishment of minimum sizes for Atlantic billfish;
- A prohibition on possession of Atlantic billfish by commercial longline and drift net vessels; and
- Establishment of data reporting requirements.

As previously mentioned, passage of the 1996 Magnuson-Stevens Act initiated fundamental changes in U.S. fishery management policy, shifting emphasis to precautionary management strategies. In September 1997, NMFS listed fishery resources considered to be overfished, which included Atlantic blue and white marlin. This action triggered a suite of management requirements, including development of a rebuilding plan for overfished stocks, and reduction in bycatch and bycatch mortality. Further, in 1998, western Atlantic sailfish was added to the list of overfished species. In the international arena, ICCAT made its first-ever binding recommendation for Atlantic blue and white marlin in 1997. ICCAT Recommendation 97-09 required landing reductions of at least 25 percent from 1996 levels by the end of 1999. Improvements in data and monitoring were also included in this recommendation.

#### 3.1.2.3 Interim Rules

On March 24, 1998, NMFS published an interim rule (63 FR 14030) under section 305(c) of the Magnuson-Stevens Act, that increased the minimum size limits for Atlantic blue marlin and Atlantic white marlin to 96 inches lower jaw-fork length (LJFL) and 66 inches LJFL, respectively, and required tournament operators to notify NMFS of tournaments involving any Atlantic billfish at least four weeks prior to commencement. NMFS utilized the increases in size limits to immediately reduce overfishing, and to implement the 1997 ICCAT recommendation, as required by the ATCA. NMFS published an extension and amendment of the interim rule on September 29, 1998 (63 FR 51859), that:

- Further increased the minimum size for Atlantic blue marlin to 99 inches LJFL;
- Restated the minimum size for Atlantic white marlin as 66 inches LJFL;
- Established a recreational bag limit of one Atlantic marlin (blue or white marlin) per vessel per trip;
- Granted the Assistant Administrator for Fisheries (AA) the authority to adjust the bag limit, with a three-day notice, including adjustment to a zero bag limit, if necessary to meet international and domestic management objectives; and
- Continued requirements to notify NMFS of tournaments involving any Atlantic billfish at least 4 weeks prior to commencement. NMFS amended the interim rule on November 13, 1998 (63 FR 63421) by removing the adjustable bag limit provision.

Internationally, ICCAT adopted its second binding recommendation regarding billfish in November 1998. ICCAT Recommendation 98-10 built upon the previously discussed ICCAT Recommendation 97-09 by limiting landings of Atlantic blue and white marlin in the year 2000 to no more than levels required to be achieved by the end of 1999.

#### 3.1.2.4 Amendment One to the Atlantic Billfish Fishery Management Plan

In response to Magnuson-Stevens Act requirements, and concurrent with efforts on the interim rule discussed above, NMFS prepared Amendment One to the Atlantic Billfish Fishery Management Plan and published final regulations on May 28, 1999 (64 FR 29090). Amendment One maintained the objectives of the original 1988 Billfish FMP and identified the following additional objectives. As described in Chapter 1, this document consolidates these objectives with the objectives of the 1999 Atlantic Tunas, Swordfish, and Sharks FMP.

1. Prevent and/or end overfishing of Atlantic billfish and adopt the precautionary approach to fishery management;
2. Rebuild overfished Atlantic billfish stocks, and monitor and control all components of fishing mortality, both directed and incidental, so as to ensure the long term sustainability of the stocks and promote Atlantic-wide stock recovery to the level where MSY can be supported on a continuing basis;
3. Establish a foundation for the adoption of comparable international conservation and management measures, through international entities such as ICCAT, to rebuild

overfished fisheries and to promote achievement of optimum yield for these species throughout their range, both within and beyond the EEZ;

4. Minimize, to the extent practicable, release mortality in the directed billfish fishery, and minimize, to the extend practicable, bycatch and discard mortality of billfish on gears used in other fisheries;
5. Better coordinate domestic conservation and management of the fisheries for Atlantic tunas, swordfish, sharks, and billfish, considering the multispecies nature of many highly migratory species (HMS) fisheries, overlapping regional and individual participation, international management concerns, and other relevant factors;
6. Provide the data necessary for assessing the fish stocks and managing the fisheries, including addressing inadequacies in collection and ongoing collection of social, economic, and bycatch data on Atlantic billfish fisheries;
7. Coordinate domestic regulations and ICCAT conservation measures for controlling Atlantic-wide fishing mortality;
8. Consistent with other objectives of the amendment, manage Atlantic billfish fisheries for the continuing OY, so as to provide the greatest overall benefit to the Nation, particularly with respect to recreational opportunities and taking into account the protection of marine ecosystems. Optimum yield is the maximum sustainable yield from the fishery, as reduced by any relevant social, economic, or ecological factors;
9. Minimize adverse social and economic effects on recreational and commercial activities to the extent practicable, consistent with ensuring achievement of the other objectives of this plan, and with all applicable laws;
10. Maximize protection of areas identified as essential fish habitat for Atlantic billfish, particularly for critical life stages; and
11. Promote the live release of Atlantic billfish through active outreach and educational programs.

Primary management measures included:

- Adjustment of minimum size regulations for Atlantic billfish;
- A prohibition on the retention of longbill spearfish;
- Maintenance of prohibitions on commercial possession and retention;
- Allowed removal of the hook from Atlantic billfish;
- A requirement for permits and logbook reporting for charterboats targeting billfish, if selected, as part of an HMS charter/headboat system;
- Implementation of billfish tournament notification requirements;
- Implementation of a June 1 to May 31 fishing year;
- Development and implementation of outreach programs; and
- An extension of the management unit for Atlantic marlins.

#### 3.1.2.5 ICCAT 2000

ICCAT adopted additional recommendations (00-13) regarding Atlantic billfish, including an international two-phased rebuilding plan for Atlantic blue and white marlin, in November 2000. Phase I of the plan required that countries (other than the United States) capturing marlins in commercial fisheries reduce white marlin landings from pelagic longline and purse seine fisheries by 67 percent and blue marlin landings by 50 percent from 1999 levels. ICCAT adopted the marlin rebuilding strategy based on the SCRS' most recent stock assessments that indicated that marlin stocks continued to be severely overfished. ICCAT Recommendation 00-13 also recommended that the United States restrict annual landings by U.S. recreational fishermen to 250 Atlantic blue and white marlin, combined, for 2001 and 2002 (Phase I). This recommendation was subsequently extended through 2006.

#### 3.1.2.6 White Marlin Endangered Species Act (ESA) Listing Review

In September 2001, NMFS received a petition filed pursuant to ESA to list white marlin as endangered or threatened throughout its range and to designate critical habitat. After conducting a comprehensive review of the status of the species, NMFS determined in September 2002 that, while Atlantic white marlin abundance had declined from historical levels, the stock was not at a level that warranted listing under the ESA. The ESA determination specified that another stock status review would occur in 2007. Also, in 2001, the HMS and Billfish Advisory Panels (Billfish AP), a group of state representatives, regional Fishery Management Council members, commercial fishing representatives, recreational fishing representatives, academics, and environmental interest group representatives, indicated that it was necessary to improve the monitoring of recreational swordfish and Atlantic billfish landings.

#### 3.1.2.7 ICCAT 2002

In 2002, Phase 1 of the ICCAT Atlantic marlin rebuilding plan was extended through the year 2005 by adoption of ICCAT Recommendation 02-13. ICCAT amended the rebuilding program by specifying that, through 2005, the annual amount of blue marlin that can be harvested and retained by pelagic longline and purse seine vessels must be no more than 50 percent of the 1996 or 1999 landing levels, whichever is greater. For white marlin, the annual amount allowed to be harvested and retained by pelagic longline and purse seine vessels must be no more than 33 percent of the 1996 or 1999 landing levels, whichever is greater. The United States had already prohibited commercial retention of billfish since the implementation of the 1988 Atlantic Billfish FMP, so it was already compliant with this recommendation. For ICCAT members other than the United States, the plan required the release of all live marlins taken as bycatch in commercial fisheries, but provided an allowance for the landing of fish unavoidably killed, provided that they were not sold. For its part of the rebuilding program, the United States agreed to continue limiting recreational landings of Atlantic blue and white marlin to 250 fish, annually, maintain its regulations prohibiting the retention of marlins by U.S. pelagic longline vessels, and continue monitoring billfish tournaments through scientific observer coverage of at least five percent initially, with the objective of 10 percent coverage by 2002. As recorded in ICCAT compliance tables, the United States remained within its 250 marlin limit in 2001 and 2003, but exceeded the 250 fish limit in 2002. At present, the United States complies with the ICCAT observer requirements by requiring that all HMS tournaments register with NMFS, selecting all billfish tournaments for reporting their results, and assigning observers to many billfish tournaments.

#### 3.1.2.8 Recreational Permitting and Reporting Rules

A key element in complying with Phase I of the ICCAT marlin rebuilding plan and improving the monitoring of recreational billfish and swordfish landings was establishing a comprehensive monitoring program for all recreational landings of marlin, sailfish and swordfish, particularly those landed outside of fishing tournaments, which are monitored through the Recreational Billfish Survey (RBS).

In early 2002, the HMS and Billfish APs again discussed monitoring U.S. recreational billfish landings, and focused upon both a landings tag program (similar to those operating for the recreational bluefin tuna fisheries in North Carolina and Maryland) and a call-in requirement for all billfish landings.

On December 18, 2002 (67 FR 77434), NMFS published a final rule requiring all vessel owners fishing for Atlantic HMS to obtain an Atlantic HMS recreational angling category permit. On January 7, 2003 (68 FR 711), a final rule establishing a mandatory reporting system for all non-tournament recreational landings of Atlantic marlins, sailfish, and swordfish was published. These requirements became effective in March 2003. These requirements, in combination with mandatory tournament reporting, are improving the ability of the United States to accurately monitor all recreational landings of Atlantic marlins, sailfish, and swordfish, however, non-compliance by recreational anglers remains a significant issue.

#### 3.1.2.9 Proposed Rule to Codify the 250 Marlin Landing Limit

On September 17, 2003, NMFS published a proposed rule (68 FR 54410) to codify an annual landings limit of 250 Atlantic blue and white marlin combined, and to implement a provision to carry forward over- and underharvest of the Atlantic blue and white marlin landing limit into subsequent fishing years, consistent with ICCAT recommendations. To remain in compliance with the landing limit and to maximize allowable landings, NMFS proposed to increase the legal recreational minimum size of Atlantic blue and white marlin for the remainder of a fishing year when 80 percent of the landing limit was projected to be achieved. If the landing limit was attained, NMFS proposed to allow only catch-and-release fishing for these species for the remainder of the fishing year. The proposed rule was not finalized due to a need to review the methodology of calculating recreational marlin landings. The proposed rule incorporated landings as reported by the Recreational Billfish Survey (RBS), and indicated landings levels of 129 fish for 2002. Application of a new methodology (scalar expansion) resulted in the United States reporting 279 marlin to ICCAT for compliance purposes for 2002, which exceeded the annual 250 fish landings limit by 29 fish. NMFS is continuing to review various methodologies to identify the most appropriate approach for estimating recreational marlin landings. The proposed rule for this current Draft HMS FMP formally withdrew this 2003 proposed rule. Similar measures to those in the 2003 proposed rule are analyzed in Chapter 4 of this document.

#### 3.1.2.10 ICCAT 2004

At the November 2004 ICCAT meeting, the United States chose not to apply the scalar expansion methodology for compliance purposes, but rather applied a methodology (RBS + Non-Tournament Reporting System + State Landing Tags) similar, but not identical to that used in the 2001 compliance report and the September 2003 Proposed Rule. Application of this methodology resulted in the United States reporting 131 marlin to ICCAT for compliance purposes in 2004. The United States is continuing to review its methodology to quantify recreationally landed marlins. Further, a new ICCAT Recommendation (as yet unnumbered) was adopted which extended Phase I of the Marlin Rebuilding Plan and delayed the planned 2005 assessment by SCRS of blue and white marlin to 2006 on the basis of inadequate data. This action resulted in an extension of the cap of 250 blue and white marlin, combined, for U.S. recreational landings through 2006.

### 3.1.3 Summary and Update of Management Measures Taken in 2005 and Early 2006

During calendar year 2005, NMFS' HMS Management Division completed numerous actions, including the release of the Draft HMS FMP, several inseason actions and proposed and final rules, and responses to several petition for rulemakings. Each of the regulatory actions is consistent with existing HMS rebuilding plans, and is supported by a regulatory analysis, as required, of the action's socio-economic and/or ecological effects. These analyses are supplements or updates to previous environmental impact statements and regulatory impact analyses, and are found in supporting documents including but not limited to environmental assessments (EA), environmental impact statements (EIS), and/or regulatory impact reviews (RIR). As reflected in these supporting documents, which are available from NMFS upon request or on the NMFS HMS Management Division's webpage, these actions are not expected to have adverse ecological impacts on target, non-target, or protected species, but are expected overall to have positive cumulative impacts. Table 3.1 provides a list of all Federal Register notices filed during 2005 relating to specific actions taken by NMFS' HMS Management Division.

In the beginning of 2006, NMFS' HMS Management Division completed additional actions including proposing and finalizing adjustment to the U.S. swordfish annual quota, proposing and finalizing the second and third 2006 fishing seasons for the Atlantic shark fishery, proposing the annual specifications for the 2006 BFT fishery, and proposing dehooking and complementary closures for the Atlantic shark bottom longline fishery. NMFS will provide a similar table of all 2006 actions related to Atlantic HMS in the 2007 SAFE Report.

Currently, there is one active lawsuit (The Ocean Conservancy v. Evans, Civ. No. 1:04-cv-1155 (D.D.C.)) relating to an HMS management action. In the summer of 2004, environmental groups challenged the July 2004 sea turtle bycatch mitigation rule that NMFS implemented for the Atlantic pelagic longline fishery and accompanying BiOp. The judge ruled in favor of NMFS in 2005; the plaintiffs have appealed the ruling.

### 3.1.4 2005 Accomplishments of the International Commission for the Conservation of Atlantic Tunas (ICCAT)

The 2005 Regular Meeting of the International Commission for the Conservation of Atlantic Tunas (ICCAT) was held November 14 – 20, 2005, in Seville, Spain. There was no new species stock assessments conducted in 2005. As such, much of the work at the 2005 Commission meeting dealt with issues such as trade and trade monitoring, compliance with existing ICCAT recommendations, bycatch, data collection, and the functioning of the Commission. For purposes of clarity, it should be understood that ICCAT recommendations are binding instruments for Contracting Parties while ICCAT resolutions are non-binding and express the will of the Commission. All ICCAT recommendations and resolutions are available on the ICCAT website at http://www.ICCAT.es.

#### 3.1.4.1 Atlantic Tunas

Despite U.S. concerns over increasing catches of juvenile yellowfin tuna, ICCAT adopted Recommendation 05-01, which repealed the longstanding 3.2 kg size limit on Atlantic yellowfin tuna, as originally established by Recommendation 72-01. The Commission also adopted Recommendation 05-02 which severely reduced the Taiwan's bigeye tuna quota in the Atlantic from 16,500 mt to 4,600 mt. This recommendation provided 3,300 mt to the directed Taiwanese bigeye tuna fleet and 1,300 mt as bycatch in the Taiwanese albacore fishery. Under this recommendation, Taiwan's directed bigeye fleet is also limited to 15 vessels and its albacore fleet is limited to 60 vessels in 2006. In addition, the measure requires Taiwan to improve monitoring and control of its fleet, to reduce overall fleet capacity in the Atlantic, and to take steps to control its business entities involved in supporting illegal, unregulated, and unreported (IUU) activities.

#### 3.1.4.2 Atlantic Sharks

ICCAT adopted Recommendation 05-05 which requires contracting parties to report on domestic implementation of *Recommendation 04-10 Concerning the Conservation of Sharks Caught in Association with Fisheries Managed by ICCAT*. For those contracting parties that had not implemented ICCAT Recommendation 04-10 at the time of the 2005 Commission meeting, Recommendation 05-05 reinforced the requirement to do so.

#### 3.1.4.3 Trade and Trade Monitoring

ICCAT adopted a number of recommendations regarding trade of HMS or tracking of trade during the 2005 Commission meeting. Recommendation 05-04 implements new requirements regarding farmed bluefin tuna including improved tracking of farmed fish for quota monitoring and trade purposes, sampling and data collection programs for assessment purposes, and other requirements to ensure the effectiveness of ICCAT conservation and management measures. To better combat IUU fishing activities, ICCAT adopted Recommendation 05-06 that establishes a program for transshipment by large-scale tuna longline fishing vessels, and procedures for transshipments that occur on the high seas and within areas of national jurisdiction. The measure establishes a record of carrier vessels authorized to receive ICCAT-managed species, and requires carrier vessels to use VMS and to have an ICCAT observer on board. It also establishes the ICCAT Regional Observer Program for placing observers on carrier vessels in the Atlantic – the first of its kind at ICCAT. The observer program will be funded by members and cooperating parties engaging in transshipment operations. The program will be operated by the ICCAT Secretariat, who is responsible for training and placement of observers.

#### 3.1.4.4 Data Compliance

ICCAT adopted Recommendation 05-09, a U.S. sponsored proposal establishing a process and procedure for reviewing compliance by ICCAT parties and cooperating parties with data submission requirements. Specifically, Recommendation 05-09 established a procedure for identifying data gaps and their causes and for developing appropriate actions to address those data problems. The measure tasks the SCRS with providing a report of data gaps and their impacts on assessments. It requires the responsible member or cooperating party to explain the reporting deficiency and provide a plan for corrective action. In addition, the measure provides that the Compliance Committee of the Commission should recommend appropriate action based on relevant information to address problematic data deficiencies.

#### 3.1.4.5 Circle Hooks

A U.S. proposal encouraging ICCAT parties to undertake research on the use of circle hooks in pelagic longline, recreational, and artisanal fisheries was adopted by the Commission as Resolution 05-08. The measure is non-binding and also includes a provision encouraging parties to share information on fishing methods and technological gear changes that improve the safe handling and release of incidentally caught species.

A number of other non-binding resolutions were adopted which can be found on the ICCAT website identified above.

### 3.1.5 Existing State Regulations

Table 3.2 outlines the existing State regulations as of May 30, 2006, with regard to HMS species. The HMS Management Division updates this table periodically throughout the year. While the HMS Management Division updates this table periodically throughout the year, persons interested in the current regulations for any state should contact that state directly.

**Table 3.2 State Rules and Regulations Pertaining to Atlantic HMS, as of May 30, 2006.**

Please note that state regulations are subject to change. Please contact the appropriate state personnel to ensure that the regulations listed below remain current. X = Regulations in Effect; n = Regulation Repealed; FL = Fork Length; CL = Carcass Length; TL = Total Length; LJFL = Lower Jaw Fork Length; CFL = Curved Fork Length; DW = Dressed Weight; and SCS = Small Coastal Sharks; LCS = Large Coastal Sharks.

## 3.2 Status of the Stocks

The thresholds used to determine the status of Atlantic HMS are fully described in Chapter 3 of the 1999 Tunas, Swordfish, and Shark FMP and Amendment 1 to the Billfish FMP, and are presented in Figure 3.1. These thresholds are based on the thresholds described in a paper describing the technical guidance for implementing National Standard 1 of the Magnuson-Stevens Act (Restrepo *et al*., 1998). These thresholds will not change as a result this Final Consolidated HMS FMP.

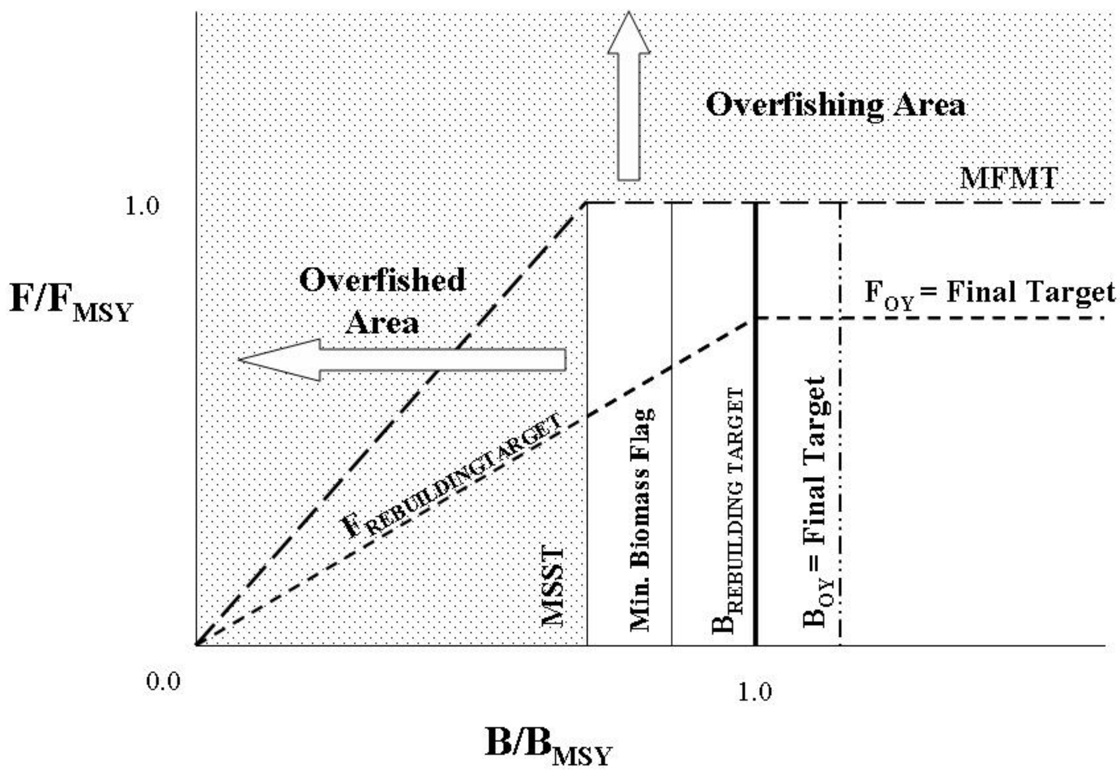

**Figure 3.1 Illustration of the status determination criteria and rebuilding terms.**

In summary, a species is considered overfished when the current biomass (B) is less than the minimum stock size threshold ($B < B_{MSST}$). The minimum stock size threshold (MSST) is determined based on the natural mortality of the stock and the biomass at maximum sustainable yield ($B_{MSY}$). Maximum sustainable yield (MSY) is the maximum long-term average yield that can be produced by a stock on a continuing basis. The biomass can be lower than $B_{MSY}$, and the stock not be declared overfished as long as the biomass is above $B_{MSST}$.

Overfishing may be occurring on a species if the current fishing mortality (F) is greater than the fishing mortality at MSY ($F_{MSY}$) ($F > F_{MSY}$). In the case of F, the maximum fishing mortality threshold is $F_{MSY}$. Thus, if F exceeds $F_{MSY}$, the stock is experiencing overfishing.

If a species is declared overfished or has overfishing occurring, action to rebuild the stock and/or prevent further overfishing is required by law. A species is considered rebuilt when B is greater than $B_{MSY}$ and F is less than $F_{MSY}$. A species is considered healthy when B is greater than or equal to the biomass at optimum yield ($B_{OY}$) and F is less than or equal to the fishing mortality at optimum yield ($F_{OY}$).

In summary, the thresholds to use to calculate the status of Atlantic HMS, as described in the 1999 FMP and Amendment, are:

- Maximum Fishing Mortality Threshold (MFMT) = $F_{limit}$ = $F_{MSY}$;
- Overfishing is occurring when $F_{year} > F_{MSY}$;
- Minimum Stock Size Threshold (MSST) = $B_{limit}$ = (1-M)$B_{MSY}$ when M < 0.5 = 0.5$B_{MSY}$ when M >= 0.5 (for billfish, the specific MSST values are: blue marlin = 0.9$B_{MSY}$; white marlin = 0.85$B_{MSY}$; west Atlantic sailfish = 0.75$B_{MSY}$);
- Overfished when $B_{year}/B_{MSY}$ < MSST;
- Biomass target during rebuilding = $B_{MSY}$;
- Fishing mortality during rebuilding < $F_{MSY}$;
- Fishing mortality for healthy stocks = 0.75$F_{MSY}$;
- Biomass for healthy stocks = $B_{OY}$ = ~1.25 to 1.30$B_{MSY}$;
- Minimum biomass flag = (1-M)$B_{OY}$; and
- Level of certainty of *at least* 50 percent but depends on species and circumstances.

This final Consolidated HMS FMP does not change these threshold levels. The current status of Atlantic HMS is provided in the table below. Numerous stock assessments are expected to occur in 2006 that could change this status. Those species expected to have new stock assessments in the near future are: LCS (the review workshop – last of three – June 5-9, 2006); marlin (May 15-19, 2006); BFT (June 12-18, 2006); swordfish (September 4-8, 2006); and SCS (first workshop of three early 2007). The results of the LCS stock assessment will not be considered complete until the review workshop document is finalized, likely in summer 2006.

**Table 3.3 Stock Assessment Summary Table.** Source: SCRS, 2004 and 2005, Cortes, 2002, and Cortes *et al.* 2002.

### 3.2.1 Atlantic Swordfish

#### 3.2.1.1 Life History and Species Biology

Swordfish are members of the family *Xiphiidae*, in the suborder *Scombroidei*. Atlantic swordfish (*Xiphias gladius*) are one of the largest and fastest predators in the Atlantic Ocean, reaching a maximum size of 530 kg (1165 lb). Like other highly migratory species, they have developed a number of specialized anatomical, physiological, and behavioral adaptations (Helfman *et al.*, 1997). Swordfish are distinguished by a long bill that grows forward from the upper jaw. This bill differs from that of marlins (family *Istiophoridae*) in that it is flattened rather than round in cross section, and smooth rather than rough. Swordfish capture prey by slashing this bill back and forth in schools of smaller fish or squid, stunning or injuring their prey in the process. They may also use the bill to spear prey, or as a defense during territorial encounters. Broken swordfish bills have been found embedded in vessel hulls and other objects (Helfman *et al.*, 1997).

Atlantic swordfish are usually found in surface waters but occasionally dive as deep as 650 meters. These large pelagic fishes feed throughout the water column on a wide variety of prey including groundfish, pelagics, deep-water fish, and invertebrate. Swordfish show extensive diel migrations and are typically caught on pelagic longlines at night when they feed in surface waters (SCRS, 2004). They are capable of migrating long distances to maximize prey availability and, as noted above, can prey upon various trophic levels during their daily vertical migrations (NMFS, 1999). As adults and juveniles, swordfish feed at the highest levels of the trophic food chain, implying that their prey species occur at low densities. The foraging behavior of swordfish reflects the broad distribution and scarcity of appropriate prey; they often aggregate in places where they are likely to encounter high densities of prey, including areas near current boundaries, convergence zones, and upwellings (Helfman *et al*., 1997).

Swordfish move thousands of kilometers annually and are distributed globally in tropical and subtropical marine waters. Their broad distribution, large spawning area, and prolific nature have contributed to the resilience of the species in spite of the heavy fishing pressure being exerted on it by many nations. During their annual migration, North Atlantic swordfish follow the major currents which circle the North Atlantic Ocean (including the Gulf Stream, Canary and North Equatorial Currents) and the currents of the Caribbean Sea and Gulf of Mexico. The primary habitat in the western north Atlantic is the Gulf Stream, which flows northeasterly along the U.S. coast, then turns eastward across the Grand Banks. North-south movement along the eastern seaboard of the United States and Canada is significant (NMFS, 2003). They are found in the colder waters during summer months and all year in the subtropical and tropical area (SCRS, 2003). Additional information on life history relating to habitat can be found in Section 3.3, Essential Fish Habitat, as well as the 1999 FMP for Atlantic Tunas, Swordfish, and Sharks.

Like most large pelagic species, swordfish have adapted body contours that enable them to swim at high speeds. Their streamlined bodies are round or slightly compressed in cross section (fusiform), and their stiff, deeply forked tails minimize drag. This streamlined physical form is enhanced by depressions or grooves on the body surface into which the fins can fit during swimming. The extremely small second dorsal and anal fins of the swordfish may function like the finlets of tuna, reducing turbulence and enhancing swimming performance. Their method of respiration, known as ram gill ventilation, requires continuous swimming with the mouth open to keep water flowing across the gill surfaces, thereby maintaining an oxygen supply. This respiratory process is believed to conserve energy compared to the more common mechanism whereby water is actively pumped across the gills (Helfman *et al*., 1997). In addition to the benefits of speed and efficiency, their search for prey is aided by coloring that provides camouflage in pelagic waters. This shading is darker along the dorsal side and lighter underneath, enhanced by silvery tones.

Swordfish exhibit other physiological characteristics that enable them to extend their hunting range. For example, swordfish can maintain elevated body temperatures, conserving the heat generated by active swimming muscles. Swordfish have developed a heat exchange system that allows them to swim into colder, deep water in pursuit of prey. Because warm muscles contract faster than cool ones, heat conservation is believed to enable these predatory fishes to channel more energy into swimming speed. The internal temperatures of these fishes remain fairly stable even as they move from surface waters to deep waters. Swordfish have also adapted specialized eye muscles for deep water hunting. Because their eye muscles do not have the ability to contract, they produce heat when stimulated by the nervous system, locally warming both the brain and eye tissues (Helfman *et al*., 1997). With this modification, swordfish are able to hunt in the frigid temperatures of deep-water ocean environments without experiencing a decrease in brain and visual function that might be expected under such harsh conditions.

Juvenile swordfish are characterized as having exceptionally fast growth during the first year (NMFS, 1999). Swordfish exhibit dimorphic growth, where females show faster growth rates and attain larger sizes than males. Young swordfish grow very rapidly, reaching about 130 cm lower jaw-fork length (LJFL) by age two. Swordfish are difficult to age, but 53 percent of females are considered mature by age 5, at a length of about 130 cm LJFL (SCRS, 2003; SCRS, 2004). Approximately 50 percent of males attain maturity by 112 cm LJFL (Arocha, 1997). All males are mature by 145 to 160 cm LJFL (37 to 50 kg ww), approximately age five, and all females are mature by 195 to 220 cm LJFL (93 to 136 kg ww), approximately age nine. In general, swordfish reach 140 cm LJFL (33 kg ww) by age three and are considered mature by age five. Individual females may spawn numerous times throughout the year (NMFS, 1999).

Swordfish stocks consist of several age classes, a condition that may serve as a buffer against adverse environmental conditions and confer some degree of stability on the stocks. Swordfish are also at a high trophic level, which may make the species less vulnerable to short-term fluctuations in environmental conditions (NMFS, 1999).

When ICCAT's Standing Committee on Research and Statistics (SCRS) scientists assess the status of Atlantic swordfish, the stock is split between the North Atlantic, South Atlantic, and Mediterranean Sea. The SCRS continues to examine existing information, including spawning data, tagging information, genetic studies, and abundance indices to better define stock structure. For the purposes of domestic management, the swordfish population is considered to consist of two discrete stocks divided at 5° N.

#### 3.2.1.2 Stock Status and Outlook

The most recent assessment of North and South Atlantic swordfish stocks was conducted in 2002. In that assessment, updated CPUE and catch data through 2001 were examined. Sex and age-specific (North Atlantic) and biomass standardized catch rates (North and South Atlantic) from the various fleets were updated. The updated North Atlantic CPUE data showed similar trends to previous years, and also showed signs of improvement in stock status since 1998. In particular, the recruitment index (1997 – 2001) and the catch-at-age used in the 2002 North Atlantic assessment showed signs of substantially improved recruitment (age one), which has manifested in several age classes and the biomass index of some fisheries, and have allowed for increases in spawning biomass and a more optimistic outlook. The strong recruitments of the late 1990s promoted improvement in spawning stock biomass and should result in further improvement, if these year classes are not heavily harvested. The CPUE patterns in the South Atlantic by fleet showed contradictory patterns. Lack of important CPUE information from some fleets fishing in the South Atlantic prevented the SCRS from reconciling these conflicts (SCRS, 2004).

*North Atlantic Swordfish (all weights are given in whole weight)*

An updated estimate of maximum sustainable yield from production model analyses is 14,340 mt (range 11,500 to 15,500 mt). Since 1997, North Atlantic swordfish catches have been estimated to have remained below 14,340 mt, but the most recent years are provisional and probably represent underestimates. Details of catches for recent years are presented below in section 3.2.1.3. The biomass at the beginning of 2002 was estimated to be 94 percent (range: 75

to 124 percent) of the biomass needed to produce MSY. This estimate is up from an estimate of 65 percent of MSY in the 1998 assessment. The 2001 fishing mortality rate was estimated to be 0.75 times the fishing mortality rate at MSY (range: 0.54 to 1.06). The replacement yield for the year 2003 and beyond was estimated to be about the MSY level. As the TAC for North Atlantic swordfish for 2002 was 10,400 mt, it was considered likely that biomass would increase further under those catch levels. The TAC set for 2003 – 2005 was 14,000 mt (ICCAT Recommendation 02 – 02). Given recent fishing mortality patterns, the spawning biomass likely will increase largely owing to the very large recruitments estimated for 1997 – 2000 (SCRS, 2005). Further, given that recent (2002 – 2003) reported catch has been below estimated replacement yield, the North Atlantic swordfish biomass may have already achieved the $B_{MSY}$ level. However, noting the uncertainties inherent in the assessment, the SCRS warned against large increases over the current TAC (SCRS, 2004). The next assessment is scheduled for 2006.

*South Atlantic Swordfish*

The SCRS noted that reported total catches have been reduced since 1995, as was recommended by the SCRS. SCRS had previously expressed serious concern about the trends in stock biomass of South Atlantic swordfish based on the pattern of rapid increases in catch before 1995 that could result in rapid stock depletion, and in declining CPUE trends of some bycatch fisheries. For the 2002 stock assessment, standardized CPUE series were available for three fleets, the targeted fishery of European Community (EC) - Spain, and the bycatch fisheries of Chinese Taipei and Japan. There was considerable conflict in trends among the three CPUE series and it is unclear which, if any, of the series tracks total biomass. It was noted that there was little overlap in fishing area among the three fleets, and that the three CPUE trends could track different components (or cohorts) of the population. To address this possibility, an age-structured production model was run as a sensitivity test. For the base case production model, the Committee selected the bycatch CPUE series combined using a simple unweighted mean and the targeted CPUE series. Due to some inconsistencies in the available CPUE trends reliable stock assessment results could not be obtained (SCRS, 2004). As stated above, the next assessment is scheduled for 2006.

Reported catches of Atlantic swordfish, including discards for the period 1950 – 2004 can be found in Figure 3.2. Estimated fishing mortality rate relative to the $F_{MSY}$ for the period 1959 – 2001 can be found in Figure 3.3. Annual yield for North Atlantic swordfish relative to the estimated MSY can be found in Figure 3.4. A summary of Atlantic swordfish stock status can be found in Table 3.4

### 3.2.1.3 Effect of Regulations

*ICCAT Catch limits (all weights in this section are given in whole weight)*

The total allowable catch in the North Atlantic in 2002 was 10,400 mt (10,200 mt retained and 200 mt discarded). The reported landings were about 9,000 mt and the estimated discards were about 535 mt. The total allowable catch in the North Atlantic in 2003 was 14,000 mt (13,900 mt retained and 100 mt discarded). The reported landings in 2003 were about 10,800 mt and the estimated discards were about 460 mt. The total allowable catch in the North Atlantic in 2004 was 14,000 mt. The reported landings in 2004 were 11,867 mt with discards totaling an estimated 417 mt. Reports for year 2004 are considered provisional and subject to change (SCRS, 2005).

The total allowable catch in the South Atlantic in 2002 was 14,620 mt. The reported landings for 2002 were about 13,660 mt and reported discards were 1 mt. The total allowable catch in the South Atlantic in 2003 was 15,631 mt. The reported landings for 2003 were about 10,900 mt and reported discards were estimated to be less than 1 mt. The total allowable catch in the South Atlantic in 2004 was 15,776. The reported landings in 2004 were 12,778 mt with discards totaling an estimated 1 mt. Reports for year 2004 are considered provisional and subject to change (SCRS, 2005).

*ICCAT Minimum size limits (all weights in this section are given in whole weight)*

There are two minimum size options that are applied to the entire Atlantic: 125 cm LJFL with a 15 percent tolerance for undersized fish, or 119 cm LJFL with zero tolerance and evaluation of the discards. In the absence of size data, these calculations could not be updated or examined for 2004. In 2000, the percentage of swordfish reported landed (throughout the Atlantic) less than 125 cm LJFL was about 21 percent (in number) overall for all nations fishing in the Atlantic. If this calculation is made using reported landings plus estimated discards, then the percentage less than 125 cm LJFL would be about 25 percent. The SCRS noted that this proportion of small fish did not increase very much even though recruitment in the North has been at a high level in recent years (SCRS, 2005). Literature Cited.

*Domestic Regulations*

The domestic commercial swordfish fishery is governed by a limited access permit system with three types of permits: directed swordfish, incidental swordfish, and swordfish handgear. Anglers must also possess either a HMS Angling category permit or a CHB permit to for fish for, retain, or possess a North Atlantic swordfish. Only commercial permit holders may sell swordfish. Details of the permitting programs, including the number of permit holders can be found in section 3.9. Data on commercial catches and landings of North Atlantic swordfish are captured through observer programs, logbook reports, and dealer reports. Additional information on commercial catches, landings, and discards can be found in Chapter 0 of this document. Approximately 154,000 square miles of the Atlantic, Gulf and Caribbean have been closed to pelagic longline fishing in an effort to reduce bycatch and discards of Atlantic HMS including juvenile swordfish. Effects of the area closures on bycatch and discards can be found in Chapter 4. Recreational landings of North Atlantic swordfish are captured through mandatory tournament reports (if a tournament is selected for reporting), mandatory self-reporting of non-tournament landings, and various surveys, including the Marine Recreational Fisheries Statistics Survey and the Large Pelagics Survey. .

The United States has implemented minimum legal size regulations for Atlantic swordfish that correspond to the ICCAT 119 cm minimum size limit. Domestic minimum sizes include: the 47” lower jaw fork length, 29” cleithrum to keel length, or 33 lbs. Vessels with commercial directed and handgear swordfish permits are not constrained by trip limits when the fishery is open. Directed swordfish permit holders are limited to 15 swordfish per vessel per trip when the directed swordfish fishery is closed. Incidental commercial permit holders are limited to two swordfish per trip, except for vessels deploying squid trawl gear, which may retain five. There is a recreational bag limit of one North Atlantic swordfish per person per trip, up to a maximum of three per vessel, regardless of the length of the trip.

#### 3.2.1.4 Recent and Ongoing Research

*(The following information was taken directly from the 2005 U.S. National Report to ICCAT)*

In 2005, data from observer samples were compared against self-reported information from the U.S. large pelagic mandatory logbook reporting system, and estimates of discard mortality of swordfish, billfish, sharks and other species from the U.S. fleet were developed from that analysis for the 2005 SCRS. Estimates of small swordfish bycatch for 2002 – 2004 were compared to the average levels estimated for the late 1990's and were found to be substantially lower. Reported and observed swordfish catches, and size and catch rate patterns through 2004 were examined in support of monitoring the recovery of north Atlantic swordfish. Standardized indices of abundance were updated for the Western North Atlantic using data from the U.S. pelagic longline fleet (SCRS/2005/085). Collaborative research between various ICCAT nations and Venezuelan scientists continues on estimating the age-structure of the catch of swordfish. Results of this research will be available for the next assessment of north Atlantic swordfish. Scientists from the United States collaborated with Brazilian scientists to improve catch rate standardization procedures by offering a course on the topic in Brazil in mid-2005. Central to this collaboration is development of fisheries research capacity in Brazil through graduate student training and of stronger scientific cooperation between Brazil and the United States.

Research on measures to mitigate the interactions between pelagic longline and bycatch of marine turtles continued under a cooperative research program involving the US Atlantic pelagic longline fishery. The Northeast Distant Fishery Experiment was conducted from 2001 through 2003 on the high seas of the Western Atlantic Ocean, in an area off New Foundland known as the Grand Banks. Results of this research which was focused on reducing mortality of marine turtles interacting with pelagic longlines was recently published (Watson, *et.al.* 2005. Fishing methods to reduce sea turtle mortality associated with pelagic longlines. (Can. J. Fish. Aquat. Sci.. 62(5): 965-981). Additional cooperative research in the Gulf of Mexico was carried out in 2004 and in additional regions in 2005.

### 3.2.2 Atlantic Bluefin Tuna

All text, figures and tables for this section are from the SCRS 2004 and 2005 Reports and the U.S. National Report to ICCAT, 2005. All weights are reported as whole weights unless indicated as otherwise.

### 3.2.2.1 Life History and Species Biology

Atlantic bluefin tuna are distributed from the Gulf of Mexico to Newfoundland in the West Atlantic, from roughly the Canary Islands to south of Iceland in the East Atlantic, and throughout the Mediterranean Sea. Historically, catches of bluefin were made from a broad geographic range in the Atlantic and Mediterranean.

Atlantic bluefin tuna can grow to over 300 cm and reach more than 650 kg. The oldest age considered reliable is 20 years, based on an estimated age at tagging of two years and about 18 years at liberty, although it is believed that bluefin tuna may live to older ages. Bluefin tuna are, thus, characterized by a late age at maturity (thus, a large number of juvenile classes) and a long life span. These factors contribute to make bluefin tuna well adapted to variations in recruitment success, but more vulnerable to fishing pressure than rapid growth species such as tropical tuna species. Bluefin tuna in the West Atlantic generally reach a larger maximum size compared to bluefin caught in the East Atlantic.

Bluefin tuna in the West Atlantic are assumed to first spawn at age eight compared to ages four to five in the east Atlantic. Distribution expands with age; large bluefin are adapted for migration to colder waters. Bluefin tuna are opportunistic feeders, with fish, squid, and crustaceans common in their diet. In the West Atlantic, bluefin tuna are thought to spawn from mid-April into June in the Gulf of Mexico and in the Florida Straits. Juveniles are thought to occur in the summer over the continental shelf, primarily from about 35°N to 41°N and offshore of that area in the winter. In the East Atlantic, bluefin tuna generally spawn from late May to July depending on the spawning area, primarily in the Mediterranean, with highest concentrations of larvae around the Balearic Islands, Tyrrhenian Sea, and central and eastern Mediterranean where the sea-surface temperature of the water is about 24°C. Sexually mature fishes have also been recently observed in May and June in the eastern Mediterranean (between Cyprus and Turkey). Bluefin tuna are known to be highly migratory and the nature and extent of their ability to conduct transoceanic migrations are the subject of significant research (see section on Research below).

### 3.2.2.2 Stock Status and Outlook

The last full stock assessments for western Atlantic bluefin tuna were conducted in 2002 by the SCRS with the next scheduled for 2006. Although the next stock assessment will not be conducted until mid-2006, the 2005 SCRS reported a significant number of new research reports and studies (see Research Section below). The assessment results are similar to those from previous assessments (see

Table 3.5). They indicate that the spawning stock biomass (SSB) declined steadily from 1970 (the first year in the assessment time series) through the late 1980s, before leveling off at about 20 percent of the level in 1975 (which has been a reference year used in previous assessments). A steady decline in SSB since 1997 is estimated and leaves SSB in 2001 at 13 percent of the 1975 level. The assessment also indicates that the fishing mortality rate during 2001 on the SSB is the highest level in the series.

A noteworthy pattern of change in the fisheries since 1998 has been the trend of increase followed by a trend of decrease in catches to below TAC level. The reported total catches of western Atlantic bluefin tuna increased from about 2600 mt in 1998 to about 3,200 mt in 2002 and has subsequently fallen below 2,000 mt in 2004. The 2002 catches were the highest since 1981; however the 2004 catches were the lowest since 1982, when ICCAT catch restrictions were first established.

The Japanese longline fishery catch in the West Atlantic in 2003 was a substantial decrease from its 2002 catch level, but increased in 2004 to a level somewhat below its average catch from 1993 – 2002. This variation resulted from the adjustments made by Japan for previous quota overages. The Canadian reported landings remained at relatively stable levels over the past decade. Recent declines in U.S. landings have been attributed to a general lack of availability of large fish in the fisheries off the northeastern U.S. coast for the past several years.

Estimates of recruitment of age one fish have been generally lower since 1976. However, recruitment of age one fish in 1995 and 1998 is estimated to be comparable in size to some of the year classes produced in the first half of the 1970s. While the large decline in SSB since the early 1970s is clear from the assessment, the potential for rebuilding is less clear. Key issues are the reasons for relatively poor recruitment since 1976, and the outlook for recruitment in the future. One school of thought is that recruitment has been poor because the SSB has been low. If so, recruitment should improve to historical levels if SSB is rebuilt. Another school of thought is that the ecosystem changed such that it is less favorable for recruitment and thus recruitment may not improve even if SSB increases. To address both schools of thought, the SCRS considered two recruitment scenarios as described below and summarized in Table 3.5. (East Atlantic Bluefin tuna summary data are also provided for comparison purposes). For both scenarios, the assessment indicates that the fishing mortality on the western Atlantic bluefin resource exceeds $F_{MSY}$ and the SSB is below $B_{MSY}$ (thus overfished according to ICCAT's objective of maintaining stocks at the MSY-biomass level and as indicated in NMFS, Report to Congress, Status of Fisheries, 2005).

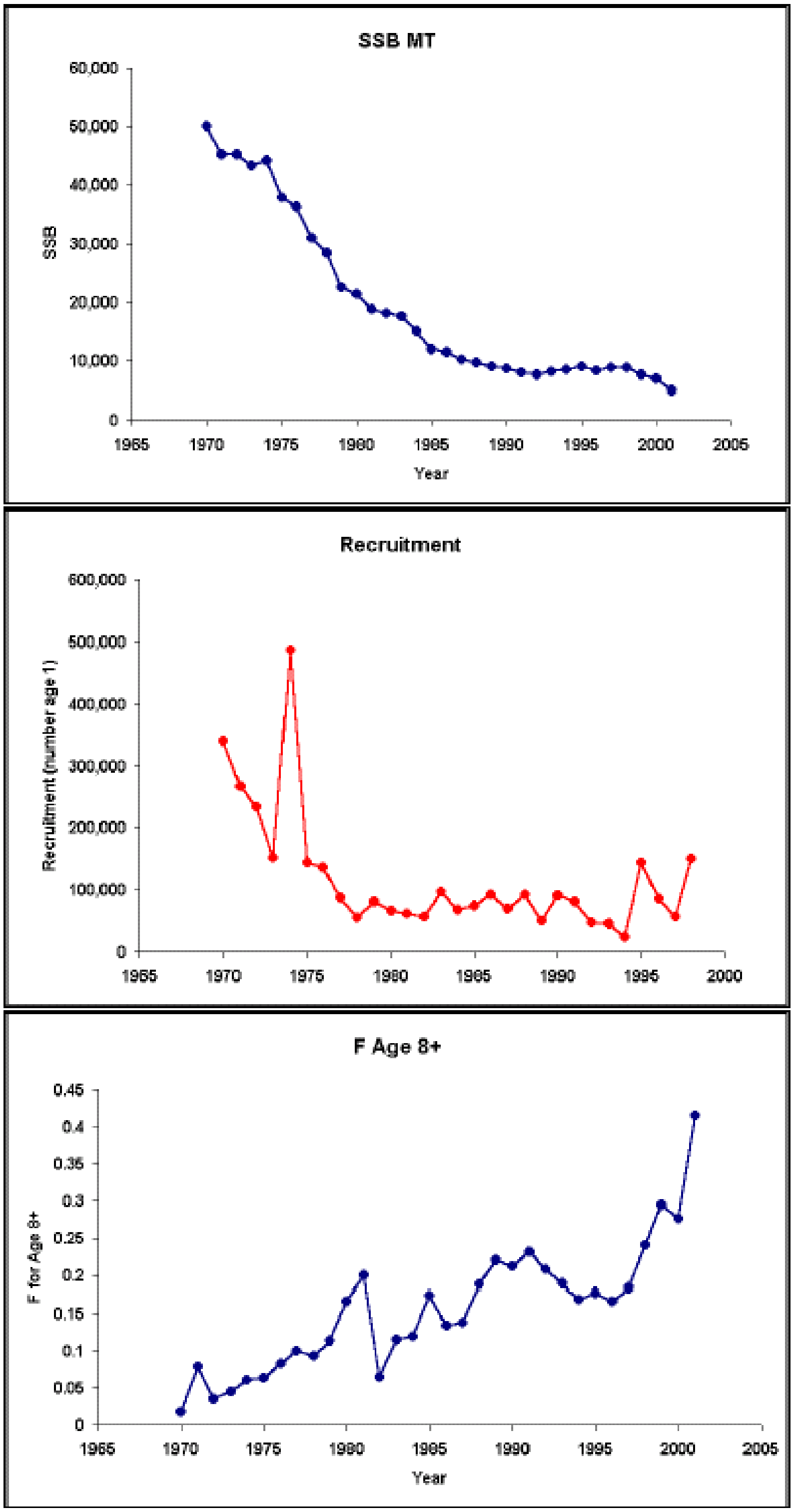

**Figure 3.5** **Western Atlantic bluefin tuna spawning biomass (t), recruitment (numbers) and fishing mortality rates for fish of age 8+, estimated by the Base Case VPA run.** Source: ICCAT, 2004.

In general, the outlook for bluefin tuna in the West Atlantic is similar to the outlook reported based on the 2000 western Atlantic bluefin tuna assessment session. The assessment and projection results for the present assessment are somewhat less optimistic than in 2000 but the confidence in the strength of the 1994 year class has increased. Therefore, the increases associated with different levels of future catch projected for the short-term are smaller but are estimated more confidently. It should be noted that the 1995 year class was estimated to be strong in 2000, but it is now estimated to be only of average strength.

As noted by the previous assessment session, western Atlantic bluefin tuna catches have not varied very much since 1983 (the range over this period is 2,106 to 3,011 mt), and the estimated spawning stock size (Spawning Stock Biomass (SSB) measured as the biomass of fish age 8+) has been relatively stable, notwithstanding the indication of a decline in the most recent years. Thus, over an extended period of time, catches around recent levels have maintained stock size at about the same level, in spite of several past assessments that predicted the stock would either decline or grow if the current catch was maintained. This observation highlights the challenge of predicting the outlook for this stock.

In order to provide advice relative to rebuilding the western Atlantic bluefin resource, the SCRS conducted projections for two scenarios about future recruitment. One scenario assumed that future average recruitment will approximate the average estimated recruitment (at age one) since 1976, unless spawning stock size declines to low levels (such as the current level estimated in the assessment, but generally lower than estimates during most of the assessment history). The second scenario allowed average recruitment to increase with spawning stock size up to a maximum level no greater than the average estimated recruitment for 1970 to 1974. These scenarios are referred to as the low recruitment and high recruitment scenarios, respectively. The low and high recruitment scenarios implied that the $B_{MSY}$ (expressed in SSB) is 42 percent and 183 percent of the biomass in 1975, respectively. With the current information, the SCRS could not determine which recruitment scenario is more likely, but both are plausible, and recommended that management strategies should be chosen to be reasonably robust to this uncertainty.

Table 3.7 below summarizes the results of projections of both scenarios at different catch levels. The projections for the low recruitment scenario estimated that a constant catch of 3,000 mt per year has an 83 percent probability of allowing rebuilding to the associated $SSB_{MSY}$ by 2018. A constant catch of 2,500 mt per year has a 35 percent probability of allowing rebuilding to the 1975 SSB by 2018.

The results of projections based on the high recruitment scenario estimated that a constant catch of 2,500 mt per year has a 60 percent probability of allowing rebuilding to the 1975 level of SSB, and there is a 20 percent chance of rebuilding SSB to $SSB_{MSY}$ by 2018. If the low recruitment scenario is valid, the TAC could be increased to at least 3,000 mt without violating ICCAT's rebuilding plan. If the high recruitment scenario is valid, the TAC should be decreased to less than 1,500 mt to comply with the plan.

The estimate of $SSB_{MSY}$ for the high recruitment scenario is critical to inferences regarding the probability of achieving rebuilding under different future levels of catch, and also less well determined by the data than $SSB_{MSY}$ for the low recruitment scenario. In particular, the estimates of $SSB_{MSY}$ based on the high recruitment scenario are substantially larger than the largest spawning stock size included in the assessment. This extrapolation considerably increases the uncertainty associated with these estimates of $SSB_{MSY}$. Previous meetings have used $SSB_{1975}$ as a rebuilding target in the context of interpreting projections. Arguably $SSB_{1975}$ is appropriate as a target level for interpreting the implications of projections based on the high recruitment scenario. Under such a target level for the high recruitment scenario, a TAC of 2,700 mt has an estimated probability of reaching the rebuilding level of about 50 percent.

The SCRS cautioned that these conclusions do not capture the full degree of uncertainty in the assessments and projections. An important factor contributing to uncertainty is mixing between fish of eastern and western origin. Furthermore, the projected increases in stock size are strongly dependent on estimates of recent recruitment, which are a particularly uncertain part of the assessment. A sensitivity test in which the estimates of the below average 1996 and the strong 1997 year classes were excluded from the analysis gave somewhat less optimistic results in terms of the estimated probabilities of recovery by 2018. However, these projections still predicted increases in spawning biomass for both recruitment scenarios, except for extreme increases in catch.

**Table 3.7 Probability of western Atlantic bluefin tuna achieving rebuilding target by 2018.** Source: ICCAT, 2004.

| | | | **High Recruitment Scenario** | |
|---|---|---|---|---|
| | | | | **$SSB_{MSY}$** |
| 500 | 95 % | 100 % | 98 % | 73 % |
| 1,000 | 89 % | 100 % | 96 % | 62 % |
| 1,500 | 77 % | 100 % | 87 % | 47 % |
| 2,000 | 60 % | 99 % | 75 % | 30 % |
| 2,300 | 45 % | 98 % | 66 % | 24 % |
| 2,500 | 35 % | 97 % | 60 % | 20 % |
| 2,700 | 26 % | 95 % | 52 % | 17 % |
| 3,000 | 14 % | 83 % | 38 % | 11 % |
| 5,000 | 0 % | 1 % | 2 % | 0 % |

#### 3.2.2.3 Effects of Regulations

The SCRS' management recommendation for the western Atlantic bluefin tuna management area is directed at the Rebuilding Program adopted by ICCAT in 1998. According to the Program, the MSY rebuilding target can be adjusted according to advice from SCRS. In 2002, ICCAT set the annual Total Allowable Catch (TAC), inclusive of dead discards, for the western Atlantic management area at 2,700 mt, effective beginning in 2003. The Program states that the TAC for the west would only be adjusted from the 2,500 mt level adopted for 2003 – 2004 if SCRS advises that (a) a catch of 2,700 mt or more has a 50 percent or greater probability of rebuilding or (b) a catch of 2,300 mt or less is necessary to have a 50 percent or greater probability of rebuilding.

The Program is designed with the intent to rebuild with 50 percent probability by 2018 to the spawning biomass level associated with MSY. In light of the uncertainty in the assessment, the choice between recruitment scenarios and rebuilding targets, and assumptions about mixing, the weight of scientific opinion within the SCRS favored no change from the current TAC of 2,500 mt per year. Projections based on the low recruitment scenario indicate that the TAC could be increased without violating the Rebuilding Program, assuming that relatively large recruitment estimates for some recent year classes are realistic. The high levels of recruitment estimated for some recent year classes are consistent with a higher biomass level as a rebuilding target. In previous assessment sessions, the spawning biomass level in 1975 was considered a useful rebuilding target. The 1975 biomass is more than twice the MSY spawning biomass level associated with the low recruitment scenario. The projections indicate a 35 – 60 percent probability of rebuilding to the 1975 spawning biomass level for a catch of 2,500 mt per year, depending on the recruitment scenario assumed. It seems likely that a recruitment scenario corresponding to a $SSB_{MSY}$ equal to the level in 1975 would indicate a probability of rebuilding by 2018 for a catch of 2,500 mt per year within the range of 35 – 60 percent.

The MSY spawning biomass associated with the high recruitment scenario, which is nearly twice the 1975 level, is unlikely to be reached by 2018 if the recent level of catch (and TAC) is maintained. However, the SCRS does not recommend the sharp reduction in TAC that would be necessary to comply with the rebuilding Program based on the high recruitment scenario because of:

- Uncertainty about the most appropriate recruitment scenario;
- Recognition that for the high recruitment scenario, the spawning biomass associated with MSY is not well determined (because estimation leads to extrapolation beyond biomass levels included within the current assessment); and
- The generally positive outlook for the resource according to the current assessment regardless of the recruitment scenario assumed.

As emphasized in previous assessments, mixing across management unit boundaries of fish of western and eastern origin could be important for management of the resource in both areas. In particular, the condition of the eastern Atlantic stock and fishery could adversely affect recovery in the West Atlantic, which was also noted in the SCRS's 1998, 2000, and 2001 reports. Therefore, the SCRS stressed the importance of continuing efforts to manage the fisheries in both the east and West Atlantic according to ICCAT's objectives.

The first regulatory measure for a scientific monitoring level was adopted for western Atlantic bluefin catches in 1981. Since then, monitoring levels have been changed in various years. Until 1987, both estimated catches and landings were below or equal to the level of the catch limits. However, from 1988 to 1997, estimated landings were very close to the level of the limits and, for some years, exceeded the limit by a maximum of 100 mt. Estimated catches (including discards) were higher than the limits every year during this period (by about 200 to 300 mt) with the exceptions of 1992 and 1997. The estimated catches exceeded the 2,500 mt limit in 2000 by 165 mt, by 218 mt in 2001, and by 715 mt in 2002. It should be pointed out that for compliance purposes, some countries (including the United States) are using fishing years that do not correspond to calendar years. Also, according to the ICCAT regulatory measure, the amount of catch that exceeded quota or was left over from the quota can be carried over to succeeding years. Hence, the catch limit set for each year could have been adjusted accordingly. The SCRS notes that the excess of the catch limits in most recent years is due to some new fisheries that operated without a quota.

For the West Atlantic, a size limit of 6.4 kg with 15 percent allowance, in number of fish, has been in effect since 1975. In addition, a prohibition on the taking and landing bluefin tuna less than 30 kg (or 115 cm) with an eight percent tolerance, by weight on a national basis, became effective in 1992. The SCRS notes that, since 1992, the proportion of undersized fish for all catches combined has been below the allowance level (*e.g.*, one percent and three percent <115cm in 2000 and 2001, respectively). Updated estimates will be available at the upcoming 2006 SCRS stock assessment.

The U.S. bluefin fishery continues to be regulated by quotas, seasons, gear restrictions, limits on catches per trip, and size limits. To varying degrees, these regulations are designed to restrict total U.S. landings and to conform to ICCAT recommendations. U.S. 2004 provisional estimated landings and discards from the northwest Atlantic (including the Gulf of Mexico), as reported by the United States to ICCAT in its annual National Report (NMFS 2005), were 899 mt and 71 mt, respectively. Those estimated landings and discards represent a decrease of 509 mt from the 2003 estimates. (Out of a total western Atlantic management area TAC of 2,700 mt, total reported catches were 2,191 mt in 2003 and about 2,000 mt in 2004). The 2004 United States landings by gear were: 32 mt by purse seine, 41 mt by harpoon, 1 mt by handline, 180 mt by longline (including discards) of which 103 mt were from the Gulf of Mexico, and 716 mt by rod and reel.

In response to 1992 regulations limiting the allowable catch of small fish by U.S. fishermen, in conformity with ICCAT agreements, enhanced monitoring of the rod and reel fishery was implemented in 1993 for the purpose of providing near real-time advice on catch levels by this fishery. This monitoring activity has continued and has included estimation of catches by finer scale size categories than reported above. The preliminary estimates for the 2004 rod and reel fishery off the northeastern United States (including the North Carolina winter fishery) for landings in several size categories were 264 fish < 66 cm, 10,193 fish 66-114 cm, 3,414 fish 115-144 cm, and 634 fish 145-177 cm (an estimated 1.5, 198, 142, and 49 mt, respectively), (NMFS 2005).

#### 3.2.2.4 Recent and Ongoing Research

As part of its commitment to the Bluefin Program, research supported by the United States has concentrated on ichthyoplankton sampling, reproductive biology, and methods to evaluate hypotheses about movement patterns, spawning area fidelity, stock structure investigations and population modeling analyses.

Ichthyoplankton surveys in the Gulf of Mexico during the bluefin spawning season were continued in 2004 and 2005. Data resulting from these surveys, which began in 1977, are used to develop a fishery-independent abundance index of spawning West Atlantic bluefin tuna. This index has continued to provide one measure of bluefin abundance that is used in SCRS assessments of the status of the resource. During the 2004 U.S. ichthyoplankton survey, a plankton net of a type used in the Spanish surveys was fished in addition to the nets normally used to determine the impact of using a wider net mouth and larger mesh on the size and catch rates of bluefin in the Gulf of Mexico. The results of this work will be reported as they become available. U.S. scientists also collaborated in development of the larval working group agenda for the Climate Impacts on Oceanic Top Predators (CLIOTOP) program managed by GLOBEC (Global Ocean Ecosystem Dynamics) initiated by SCOR and the IOC of UNESCO in 1991.

Since 1998, researchers from Texas A & M University and the University of Maryland with assistance of researchers from Canada, Europe, and Japan have studied the feasibility of using otolith chemical composition (microconstituents and isotopes) to distinguish bluefin stocks. Recent research has investigated the value of using additional microconstituent elements (transitional metals) to enhance classification success. By themselves the transitional metals provided little discriminatory power, but when combined with the other trace elements (for 13 elements in all), the classification success for several year-classes has been moderate ranging from 60 – 90 percent, and classification functions show strong year-to-year variability. In SCRS/2005/083 the utility of an alternative chemical marker in otoliths, carbon and oxygen stable isotopes, to discriminate bluefin tuna from natal regions were reported upon. The discriminatory power of stable isotopes ($\delta_{13}C$, $\delta_{18}O$) in otoliths of yearlings (age-1) was high, with 91 percent of individuals classified correctly to eastern and western nurseries. These stable isotopes and in particular $\delta_{18}O$ can be used to reliably predict nursery origin of Atlantic bluefin tuna. An initial application compared otolith core material (corresponding to the first year of life) of large school, medium, and giant category bluefin tuna to reference samples of yearling signatures to determine their origin. A large fraction (~43 – 64 percent) of the Atlantic bluefin tuna collected in the western Atlantic fishery (comprised primarily of large school and medium category fish) originated from nurseries in the east. Alternatively, medium and giant category bluefin tuna from the Mediterranean were largely (~82 – 86 percent) of eastern origin. Thus, initial evidence suggests that the western fishery received high input from the Mediterranean population. (See generally SCRS/2003/105, and Rooker et al 2001a, 2001b and 2003).

Scientists from the University of Maryland, Virginia Institute of Marine Science, and Texas A&M University have continued to sample specimens for genetic and otolith chemistry studies of stock structure. Roughly 10 – 20 young of the year were collected in 2004. In addition, limited sampling of ages 1 and older continues. Efforts are also continuing to obtain samples from juveniles and mature bluefin from the Mediterranean Sea and adjacent waters.

In response to the ICCAT Commission's request for options for alternative approaches for managing mixed populations of Atlantic bluefin tuna, SCRS/2005/108 further examined some implications of incorporating electronic tagging information on transfer rates into virtual population analyses. SCRS/2005/084 examined yield and spawner per recruit consequences of different assumed levels of mixing between eastern and western bluefin stocks to provide guidance to the Commission as requested at the 3rd Meeting of Working Group to Develop Coordinated and Integrated Bluefin Tuna Management Strategies. Researchers at the Imperial College, London, continue work with the University of Miami, the University of New Hampshire and the National Marine Fisheries Service to develop methods to estimate bluefin movement and fishing mortality rate patterns (SCRS/2005/048). Operating models are being developed which will use conventional and electronic tagging data and fishing effort by management area. These models will be used to examine possible harvest control rules and the evaluation of possible management procedures.

U.S. scientists from Stanford and Duke University along with the Monterey Bay Aquarium and NMFS have placed over 700 electronic tags in bluefin tuna in the region along the U.S. coast of North Carolina. The data from implantable archival tags has been critical for establishing the basic biology of Atlantic bluefin and the patterns of movements to feeding and breeding grounds. Results from a large number of these tags were interpreted in a paper in the journal Nature in 2005 (Block *et al.* 2005). Tagging off the Carolinas, in the Gulf of Maine, and elsewhere continued in 2004 and 2005 and more than 90 tags were placed in fish off the Carolinas in 2005. The tags are due to report 7 – 9 months from the deployment dates and will be further reported upon as results become available.

U.S. scientists from the University of New Hampshire have placed over 200 pop-up satellite archival tags on New England bluefin tuna. Ongoing efforts include examining short and long-term dispersals of bluefin in the Gulf of Maine, the identification of spawning grounds, the spatial correlation between bluefin locations and oceanographic features and continuing to determine Atlantic-wide migratory paths. Results from much of this tagging effort were recently published in the journal Marine Biology (Wilson, *et.al.* 2005).

A new research initiative in 2005 involving scientists from the University of New Hampshire, the Virginia Institute of Marine Science, and Virginia SeaGrant will place electronic tags on juvenile bluefin from off the U.S. coast of Virginia. As results become available, they will be reported upon.

A recent publication by Fromentin and Powers (2005), titled "Atlantic bluefin tuna: population dynamics, ecology, fisheries and management" provides an extensive summary of old and new information on the biology and ecology of Atlantic bluefin tuna and associated fishery management implications. The abstract reads as follows:

> "Both old and new information on the biology and ecology of Atlantic bluefin tuna have confronted scientists with research challenges: research needs to be connected to current stock-assessment and management issues. We review recent studies on habitat, migrations and population structure, stressing the importance of electronic tagging results in the modification of our perception of bluefin tuna population dynamics and behavior. Additionally, we question, from both scientific and management perspectives, the usefulness of the classical stock concept and suggest other approaches, such as Clark's contingent and metapopulation theories. Current biological information confirms that a substantial amount of uncertainty still exists in the understanding of reproduction and growth. In particular, we focus on intriguing issues such as the difference in age-at-maturity between West Atlantic and Mediterranean bluefin tuna. Our description of Atlantic bluefin tuna fisheries places today's fishing patterns within the two millennium history of exploitation of this species: we discuss trap fisheries that existed between the 17th and the early 20th centuries; Atlantic fisheries during the 1950s and 1960s; and the consequences of the recent development of the sushi–sashimi market. Finally, we evaluate stock status and management issues since the early 1970s. While important

uncertainties remain, when the fisheries history is confronted with evidence from biological and stock-assessment studies, results indicate that Atlantic bluefin tuna has been undergoing heavy overfishing for a decade. We conclude that the current exploitation of bluefin tuna has many biological and economic traits that have led several fish stocks to extreme depletion in the past."

In 1982, ICCAT established a line separating the eastern and western Atlantic management units based on discontinuities in the distribution of catches at that time in the Atlantic and supported by limited biological knowledge. The United States is allocated quota from the western Atlantic management unit where the U.S. fisheries primarily occur. However, the overall distribution of the catch in the 1990s is much more continuous across the North Atlantic than was seen in previous decades. Tagging evidence indicates that movement of bluefin across the current east/west management boundary in the Atlantic does occur, that movements can be extensive (including trans-atlantic) and complex, that there are areas of concentration of electronically tagged fish (released in the west) in the central North Atlantic just east of the management boundary, and that fisheries for bluefin tuna have developed in this area in the last decade. At least some of these fish have moved from west of the current boundary.

Complementary studies, which might show east to west movement, are less advanced. The composition and natal origin of these fish in the central North Atlantic area are not known. The SCRS emphasizes that "it is clear that the current boundary does not depict our present understanding of the biological distribution and biological stock structure of Atlantic bluefin tuna." The SCRS also notes that "the current boundary is a *management* boundary and its effectiveness for management is a different issue."

There has been an accumulation of evidence on bluefin tuna mixing in the last few years through the collection of tagging data and its examination through the modeling of mixing scenarios for evaluating their effect on management. However, the origin of fish older than one year still remains unknown. Mixing results were reviewed in 2001 by the Workshop on Bluefin Tuna Mixing. This research led to a long-term plan for modeling finer scale spatial mixing and to short-term strategies for assessment to assist the advice for management. The data and research were reviewed again in 2002.

ICCAT, at its 2002 Meeting in Bilbao, called for a *Working Group to Develop Integrated and Coordinated Atlantic Bluefin Tuna Management Strategies,* which met in 2003 and again in 2004. In response to the recommendations from these meetings, the SCRS is developing a revised proposal for initiating a coordinated Bluefin Tuna Research Program to address priority research and data needs for providing scientific advice to ICCAT related to revised management procedures for bluefin tuna. Uncertainty exists regarding the importance and impacts of mixing on western stocks. The most important uncertainty regarding management advice by the SCRS for the eastern stock is the uncertainty in the catch data that are being taken.

More than 20 scientific documents related to bluefin tuna biology were presented to the 2005 SCRS. Many of the contributions dealt with the important issue of stock structure and mixing, and new information is available for both stocks. In particular, studies of otolith microchemistry and genetics have resulted in advances in our understanding of this component of the biology of bluefin tuna. These results continue to advance our knowledge about the overlapping distribution of fish originating from the east and the west. Therefore, the SCRS continues to question present hypotheses on stock identification. While these results are promising, more complete sampling and development of appropriate analytical approaches are required. The SCRS also received contributions relating to age and growth, sampling, parasitology and condition of bluefin tuna.

### 3.2.3 Atlantic BAYS Tuna

All text, figures and tables for this Section are from the SCRS 2004 and 2005 Reports and the U.S. National Report to ICCAT, 2005. All weights are reported as whole weights unless indicated as otherwise.

#### 3.2.3.1 Atlantic Bigeye Tuna

*Life History and Species Biology*

The geographical distribution of bigeye tuna is very wide and covers almost the entire Atlantic Ocean between 50°N and 45°S. This species is able to dive deeper than other tuna species and exhibits extensive vertical movements. Similar to the results obtained in other oceans, pop-up tagging and sonic tracking studies conducted on adult fish in the Atlantic has revealed that they exhibit clear diurnal patterns being much deeper in the daytime than at night. Spawning takes place in tropical waters when the environment is favorable. From the nursery areas in tropical waters, juvenile fish tend to diffuse into temperate waters as they grow larger. Catch information from the surface gears indicate that the Gulf of Guinea is a major nursery ground for this species.

Dietary habits of bigeye tuna are varied such that prey organisms like fish, mollusks, and crustaceans are found in stomach contents. A growth study based on otolith and tagging data resulted in the adoption by the SCRS of a new growth curve (Report of the SCRS, 2004). The curve shows bigeye tuna exhibit relatively fast growth: about 105 cm in fork length at age three, 140 cm at age five, and 163 cm at age seven. Bigeye tuna become mature at about age three and a half. Young fish form schools mostly mixed with other tunas such as yellowfin and skipjack. These schools are often associated with drifting objects, whale sharks, and sea mounts. This association appears to weaken as bigeye tuna grow larger. An estimate of natural mortality (M) for juvenile fish was provided based on the results of a tagging program. According to this study, mortality for juvenile fish only is at a similar level of M as that currently used for the entire Atlantic stock as well as the level of M used for all other oceans. Various evidence including a genetic study, the time-area distribution of fish, and movements of tagged fish suggest an Atlantic-wide single stock for this species, which is currently accepted by the SCRS. However, the possibility of other scenarios, such as north and south stocks, should not be disregarded.

*Stock Status and Outlook*

ICCAT's SCRS conducted a new stock assessment for bigeye tuna in July 2004 using various types of models. However, there were considerable sources of uncertainty arising from the lack of information regarding (a) reliable indices of abundance for small bigeye from surface fisheries, (b) the species composition of Ghanaian fisheries that target tropical tunas, and (c) details on the historical catch and fishing activities of Illegal, Unregulated, Unreported (IUU) fleets (*e.g*., size, location and total catch).

Three indices of relative abundance were available to assess the status of the stock (Figure 3.6). All were from longline fisheries conducted by Japan, Chinese Taipei, and United States. While the Japanese indices have the longest duration since 1961 and represent roughly 20 – 40 percent of the total catch, the other two indices are shorter and generally account for a smaller fraction of the catch than the Japanese fishery. These three indices primarily relate to medium and large-size fish.

Various types of production models were applied to the available data and the SCRS notes that the current year's model fits to the data were better than in past assessments, although they required similar assumptions regarding stock productivity. The point estimates of MSY obtained from different production models ranged from 93,000 mt to 113,000 mt. The lower limit of this range is higher than the one estimated in the 2002 assessment, probably due to the revised indices and the addition of a new index. An estimate obtained from another age-aggregated model was 114,000 mt. The inclusion of estimation uncertainty would broaden this range considerably.

These analyses estimate that the total catch was larger than the upper limit of MSY estimates for most years between 1993 and 1999, causing the stock to decline considerably, and leveling off thereafter as total catches decreased. These results also indicate that the current biomass is slightly below or above (85 – 107 percent) the biomass at MSY (Figure 3.7), and that current fishing mortality is also in the range of 73 percent to 101 percent of the level that would allow production of MSY (Table 3.8). However, indications from the most targeted and wide-ranging fishery are of a more pessimistic status than implied by these model results. Several types of age-structured analyses were conducted using the above-mentioned longline indices from the central fishing grounds and catch-at-age data converted from the available catch-at-size data. In general, the trajectories of biomass and fishing mortality rates are in accordance with the production model analyses. Model fits appeared improved over those of past assessments, apparently as a result of using a new growth curve for the calculation of catch at age.

The most noteworthy trend in fisheries observed is the general declining trend in catches for all gears after a high peak (121,000 mt) in 1999. After that, the total annual catch has steadily declined to a current low of 72,000 mt for 2004. The decline of longline catch is mostly attributable to the decrease of Japanese and estimated IUU catches while the other country/entity's catches are generally maintained. Other gears (purse seine and baitboat) also indicated a similar but more variable decline. The decline of the Japanese catch is related to the reduced fishing effort as well as the declined CPUE in the major fishing grounds in tropical waters.

Among the fisheries catching bigeye, two changes are noted. One is an increase in catch from the northern Islands (Azores and Madeira) area due to baitboat fisheries after four years of low catch for 2000 – 2003. Another change is also observed for the fishing area of Japanese longline fishery. Since around 2001, some of the fleet had operated in central north Atlantic between 25°N – 35°N and 40°W – 75°W. In addition to the above changes in fisheries, several countries increased their individual catch levels in 2004, although the overall catch total did not significantly increase. Such increases are reported for Philippines (1,850 mt), Venezuela (1,060 mt) and Korea (630 mt). The current reported catch of Chinese Taipei for 2003 is considered under-estimated. Chinese Taipei will re-estimate the bigeye catch for 2003 in near future. The new estimate is expected to be higher than the current reported catch.

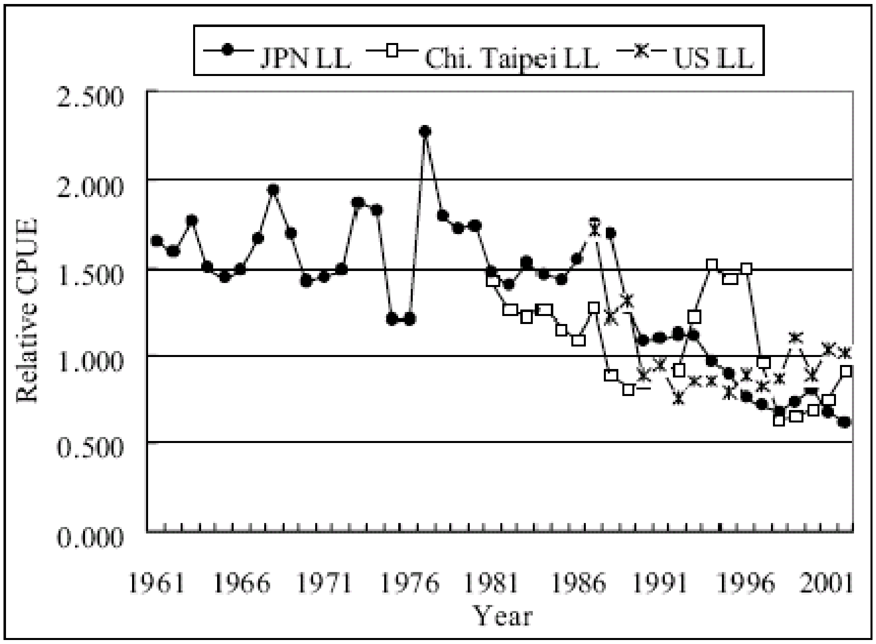

**Figure 3.6 Abundance indices in numbers of BET. All ages are aggregated.** Source: ICCAT, 2004.

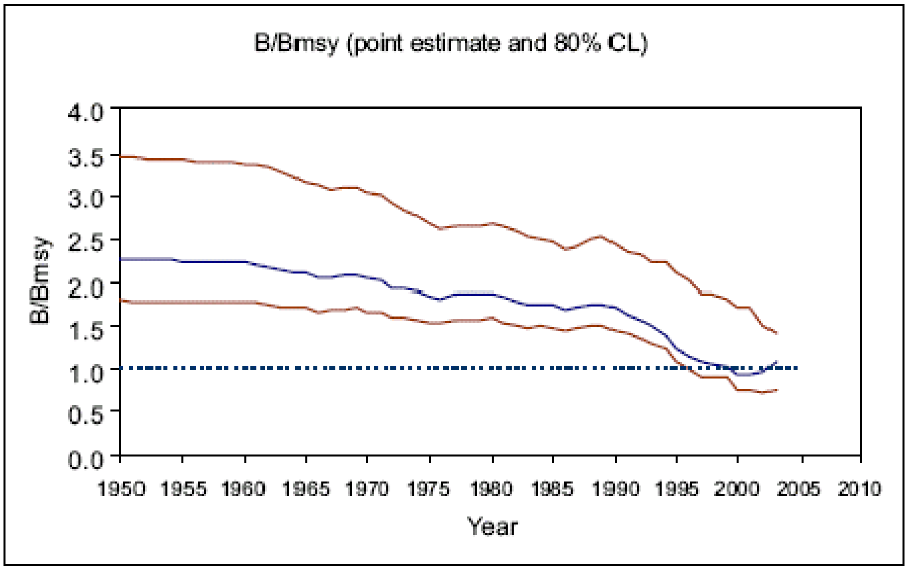

**Figure 3.7** **Trajectory of the BET biomass modeled in production model analysis (middle line) bounded by upper and lower lines denoting 80 percent confidence intervals.** Source: ICCAT, 2004.

**Table 3.8** **Summary Table for the Status of Atlantic Bigeye Tuna.** Source: ICCAT, 2005.

| | |
|---|---|
| **Age/size at Maturity** | Age 3/~100 cm curved fork length |
| **Spawning Sites** | Tropical waters |
| **Current Relative Biomass Level**<br><br>*Minimum Stock Size Threshold* | $B_{03}/B_{MSY}$ = 0.85 - 1.07<br><br>$0.6B_{MSY}$ (age 2+) |
| **Current Relative Fishing Mortality Rate**<br><br>*Maximum Fishing Mortality Threshold* | $F_{02}/F_{MSY}$ = 0.73-1.01<br><br>$F_{year}/F_{MSY}$ = 1.00 |
| **Maximum Sustainable Yield** | 93,000 - 114,000 mt |
| **Current (2004) Yield** | 72,000 mt |
| **Current (2003) Replacement Yield** | 89,000 - 103,000 mt |
| **Outlook** | Overfished; overfishing is occurring |

This assessment indicated that the stock has declined due to the large catches made since the mid-1990s to around or below the level that produces the MSY, and that fishing mortality exceeded $F_{MSY}$ for several years during that time period. Projections indicate that catches of more than 100,000 mt will result in continued stock decline. ICCAT should be aware that if major countries were to take the entire catch limit set under the ICCAT Recommendations and other countries were to maintain recent catch levels, then the total catch could exceed 100,000 mt. The SCRS highly recommended that catch levels of around 90,000 mt or lower be maintained at least for the near future for ICCAT to rebuild the stock.

*Effects of Regulations*

The bigeye minimum size regulation of 3.2 kg (Recommendation 79-01) was adopted in 1980 to reinforce the same regulation for yellowfin, and was in effect until 2004. The Committee did not evaluate this regulation at this time. However, the recommendation regarding the minimum size regulation was dropped as it was not feasible to sort the undersized bigeye and yellowfin tuna from purse seine and bait-boat catch mixed with regulation sized small skipjack without large quantities of dead discards of small bigeye and yellowfin tuna. Conversely strict enforcement of the regulation would have likely meant the closure of one of the largest tuna fisheries in the Atlantic. While the measure was in effect, it is believed that a large quantity (around 50 percent in total number of fish) of juvenile bigeye tuna smaller than 3.2 kg was caught in 2004 as well, because there are no substantial changes in the fisheries (the equatorial surface fleets) that account for most of the juvenile catch.

ICCAT asked the SCRS to examine the impact on stocks of the current minimum size regulation (bigeye tuna Recommendation 04-01). At the same time, ICCAT also asked the SCRS to recommend the necessary modifications that would improve its effectiveness as well as to review possible modifications to be applied to the closure. Although the new regulation has not been implemented yet, the SCRS met to provide a response to the Commission.

Previous yield-per-recruit and spawner-per-recruit analyses highlighted the potential importance of reducing fishing mortality on small fish. However, the percentage of fish caught less than this minimum size (3.2 kg) is very high (46 – 62 percent of the total fish caught) since 1989. The SCRS, therefore, recommends the full implementation of the moratorium on Fish Aggregation Device (FAD) fishing by all surface fisheries in the Gulf of Guinea. The moratorium on FAD fishing by surface gears in the Gulf of Guinea were observed by all fishing sectors, including Ghanaian surface fleet during 2004/2005 season. However, available purse seine catch and effort data indicated significant fishing on FADs in the moratorium area.

Limiting the annual catch to the average catch in two years of 1991 and 1992 entered into force for the major fishing countries whose 1999 catch reported to the 2000 SCRS was larger than 2,100 mt (Recommendation 01-01). The 2003 and 2004 total reported catch for the major countries and fishing entities to which the catch limit applies (EC-Spain, EC-France, EC-Portugal, Japan, Ghana, China and Chinese Taipei) were 67,000 mt and 59,500 mt, respectively. These were much lower than the total catch limit (84,200 mt) for these counties/entities. As a whole, the total catch in 2003 and 2004 for all countries is about 12,000 mt and 24,000 mt lower than the average total catch of 1991 and 1992 (96,000 mt).

Total reported U.S. bigeye tuna catches and landings (preliminary) for 2004 decreased by 69 mt from 483 mt in 2003 to 414 mt. Note that like yellowfin tuna, the estimates of rod and reel catch are considered provisional and may be revised based on results of a future review of recreational harvest estimates.

The SCRS noted its appreciation for the effort made by ICCAT in establishing the Statistical Document Program for bigeye tuna and expressed hope that the data to be submitted to the Secretariat will be useful to improve estimates of unreported catches. The SCRS also stated its appreciation regarding the initiatives to reduce the IUU activities taken by several fishing authorities. These efforts are helpful in identifying and reducing the unreported catches in the Atlantic and will make the catch limit regulation more effective, and thus will contribute to reduce uncertainties in the bigeye stock assessment. As far as the IUU catches of bigeye tuna are concerned, they are almost disappearing according to the available estimates. Nevertheless, the SCRS expressed concern that unreported catches may have been underestimated.

*Recent and Ongoing Research*

In addition to monitoring catch and effort statistics for tropical tunas that include bigeye tuna, United States scientists participated in the 2005 ICCAT Workshop on Methods to Reduce Mortality of Juvenile Tropical Tunas, held in Madrid from 4 – 8 July, 2005. Document SCRS/2005/063 used the ICCAT Task 2 catch and effort data to estimate expected changes in the catches of tropical tunas attributable to replacing the current moratorium with a time-area closure (Recommendation 04-01). The results indicate that catches of tropical tunas are expected to increase substantially if the time-area closure replaces the current moratorium. Considering that the current ICCAT hypothesis is that purse-seine fleet efficiency gains three percent per year, the net change could in fact be a large overall increase to levels above the pre-moratoria fishing mortality rate levels. SCRS/2005/079 explored the expectations for catches of undersized bigeye tuna considering the agreement reached in Recommendation 04-01. In all cases examined, total catches can be expected to increase from 5.5 to 6.7 percent as a result of Recommendation 04-01, and catches of bigeye tuna can be expected to increase from 16 to 22.1 percent. In all cases, catch of juvenile bigeye tuna increases.

U.S. scientists from the University of Miami's Rosenstiel School of Marine and Atmospheric Science continue to collaborate with EC scientists on the EU-funded assessment and management modeling project titled Framework for the Evaluation of Management Strategies (FEMS) project, on management strategy evaluations related to tropical tuna fisheries.

#### 3.2.3.2 Atlantic Yellowfin Tuna

*Life History and Species Biology*

Yellowfin tuna is a cosmopolitan species distributed mainly in the tropical and subtropical oceanic waters of the three oceans, where they form large schools. The sizes exploited range from 30 cm to 170 cm fork length (FL). Smaller fish (juveniles) form mixed schools with skipjack and juvenile bigeye tuna, and are mainly limited to surface waters, while larger fish are found in surface and sub-surface waters. The majority of the long-term recoveries of tagged fish have been tagged in the western Atlantic and recovered in the eastern Atlantic, where several recaptures are recorded each year.

Sexual maturity occurs at about 100 cm FL. Reproductive output among females has been shown to be highly variable, although the extent of this is unknown. The main spawning ground is the equatorial zone of the Gulf of Guinea, with spawning occurring from January to April. Juveniles are generally found in coastal waters off Africa. In addition, spawning occurs in the Gulf of Mexico, in the southeastern Caribbean Sea, and off Cape Verde, although the relative importance of these spawning grounds is unknown.

Although such separate spawning areas might imply separate stocks or substantial heterogeneity in the distribution of yellowfin tuna, a single stock for the entire Atlantic is assumed as a working hypothesis (Atlantic Yellowfin Working Group, Tenerife, 1993). This hypothesis indicates yellowfin are distributed continuously throughout the entire tropical Atlantic Ocean by taking into account tagging data showing transatlantic migration (from west to east), a 40-year time series of longline catch data, and other information such as time-area size frequency distributions and locations of fishing grounds).

Growth patterns are variable with size, being relatively slow initially, and increasing by the time the fish leave the nursery grounds. Males are predominant in the catches of larger sized fish. Natural mortality is assumed to be higher for juveniles than for adults. Tagging studies for Pacific yellowfin supports this assumption.

*Stock Status and Outlook*

A full assessment was conducted by the SCRS/ICCAT for yellowfin tuna in 2003 applying various age-structured and production models to the available catch data through 2001.

The variability in overall catch-at-age is primarily due to variability in catches of ages zero and one (note that the catches in numbers of age zero and especially age one were particularly high during the period 1998 – 2001). Both equilibrium and non-equilibrium production models were examined in 2003 and the results are summarized in Table 3.9. The estimate of MSY based upon the equilibrium models ranged from 151,300 to 161,300 mt; the estimates of $F_{2001}/F_{MSY}$ ranged from 0.87 to 1.29. The point estimates of MSY, based upon the non-equilibrium models, ranged from 147,200 – 148,300 mt. The point estimates for $F_{2001}/F_{MSY}$ ranged from 1.02 to 1.46. The main differences in the results were related to the assumptions of each model. The SCRS was unable to estimate the level of uncertainty associated with these point estimates. An age-structured virtual population analysis (VPA) was made using eight indices of abundance. The results from this model were more comparable to production model results than in previous assessments, owing in part to a greater consistency between several of the indices used. The VPA results compare well to the trends in fishing mortality and biomass estimated from production models. The VPA estimates that the spawning biomass (Table 3.7) and the levels of fishing mortality (Table 3.8) in recent years have been very close to MSY levels. The estimate of MSY derived from these analyses was 148,200 mt.

In summary, the age-structured and production model analyses implied that although the 2001 catches of 159,000 mt were slightly higher than MSY levels, effective effort may have been either slightly below or above (up to 46 percent) the MSY level, depending on the assumptions. Consistent with these model results, yield-per-recruit analyses also indicated that 2001 fishing mortality rates could have been either above or about the level which could produce MSY. Yield-per-recruit analyses further indicated that an increase in effort is likely to decrease the yield-per-recruit, while reductions in fishing mortality on fish less than 3.2 kg could result in substantial gains in yield-per-recruit and modest gains in spawning biomass-per-recruit.

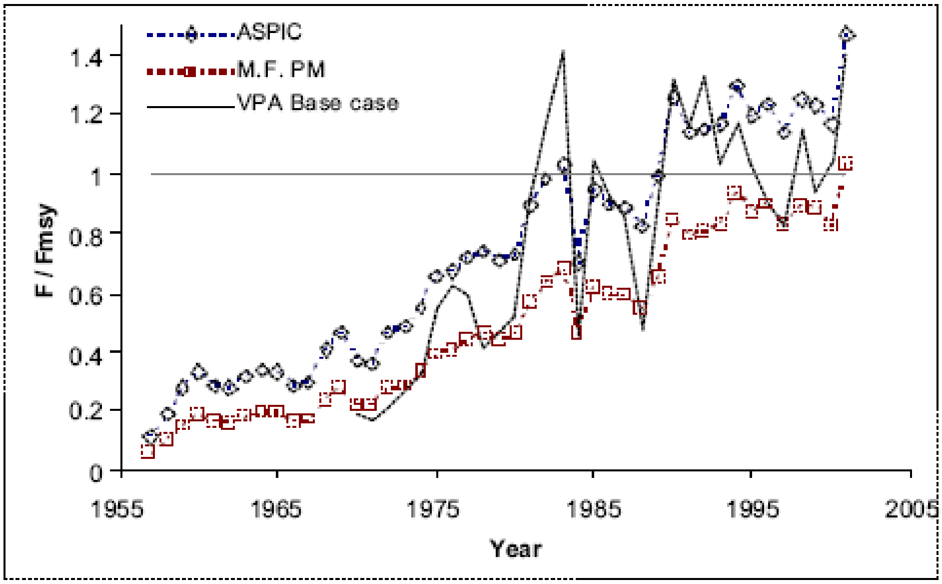

**Figure 3.9 Comparison of relative fishing mortality trends calculated using VPA and non-equilibrium production models.** Source: ICCAT, 2004.

In contrast to the increasing catches of yellowfin tuna in other oceans worldwide, there has been a steady decline in overall Atlantic catches since 2001. Atlantic surface fishery catches have shown a declining trend from 2001 to 2004, whereas longline catches have increased. In the eastern Atlantic, purse seine catches declined from 89,569 mt in 2001 to 58,632 mt in 2004, a 35 percent reduction. Baitboat catches declined by 23 percent, from 19,886 mt to 15,277 mt. This decrease is almost entirely due to reduced catches by Ghana baitboats, which resulted from a combination of reduced days fishing, a lower number of operational vessels, and the observance of the moratorium on fishing using floating objects. Catches by other baitboat fleets were generally increasing. In the western Atlantic, with the majority of the landings reported by the United States, Mexico, Venezuela, Brazil and St. Vincent and Grenadines, purse seine catches declined from 13,072 mt to 3,217 mt, a 75 percent reduction. In addition, baitboat catches also declined by eight percent from 7,027 mt to 6,735 mt. However, for the same time period, longline catches were increasing. In the eastern Atlantic, longline catches increased from 5,311 mt to 10,851 mt, a 104 percent increase. In the western Atlantic, longline catches increased from 12,740 mt to 15,008 mt, an 18 percent increase.

At the same time, the nominal effort in the purse seine fishery was declining. As an indicator, the number of purse seiners from the European and associated fleet operating in the Atlantic declined from 46 vessels in 2001 to 34 vessels in 2004. On the other hand, the European and associated baitboat fleet increased from 16 to 22 vessels during the same period. Of the relevant scientific documents presented to the 2005 SCRS, most were descriptive of the catches by country fleets. Three papers discussed observer programs in Ghana, Uruguay, and Spain, and three papers analyzed catches in the context of the moratorium. No new standardized catch rate information has been presented since the last assessment. However, examination of nominal catch rate trends from purse seine data suggest that catch-per-unit effort was stable or possibly declining since 2001 in the East Atlantic, and was clearly declining in the West Atlantic.

Since effort efficiency was estimated to have continued to increase, adjustments for such efficiency change would be expected to result in a steeper decline. Also, the average weights in European purse seine catches have been declining since 1994, which is at least in part due to changes in selectivity associated with fishing on floating objects.

Recent signals in the fishery data could result in a substantially different evaluation of stock status than that which is summarized above. It is important that the next assessment take these and other indicators (such as age of vessels and any loss of regional yellowfin fisheries) into account.

*Effects of Regulations*

Estimated catches of yellowfin tuna have averaged 141,000 mt over the past three years. This average falls near the lower estimate of the range of MSY from the age-structured and production model analyses conducted during the 2003 assessment. The SCRS considers that the yield of 159,000 mt in 2001 is likely somewhat above the replacement yield and those levels of fishing effort and fishing mortality may have been near MSY. Total catches since 2001 have been declining, but without a new assessment the SCRS in 2005 reaffirms its support for ICCAT's 1993 recommendation "that there be no increase in the level of effective fishing effort exerted on Atlantic yellowfin tuna, over the level observed in 1992." (During the 2003 assessment, the SCRS' estimates of effective fishing effort for recent years fell near the estimate for 1992).

In 1973, ICCAT adopted a regulation that imposed a minimum size of 3.2 kg for yellowfin tuna, with a 15 percent tolerance in the number of undersized fish per landing. This regulation has not been adhered to internationally, as the proportion of landings of yellowfin tuna less than 3.2 kg has been far in excess of 15 percent per year for the purse seine and baitboat fisheries. Based on the catch species composition and catch-at-size data available during the 2003 assessment, yearly catches in number ranged between 54 percent and 72 percent undersized yellowfin tuna by purse seiners and from 63 percent to 82 percent undersized fish for baitboats over the period 1997 – 2001. Landings of undersized fish occur primarily in the equatorial fisheries. Unfortunately, it is difficult to realize substantial reductions in catches of undersized fish in these fisheries because small yellowfin tuna are mostly associated with skipjack tuna, especially when fishing occurs on floating objects; thus it is difficult to avoid catching small yellowfin when catching skipjack, the latter being an important component of eastern Atlantic (equatorial) purse seine fleet catches.

Unfortunately, the use of minimum size limits as a means of reducing the mortality of juvenile tuna remains extremely problematic in this fishery for several reasons which are described in detail in "Report of the 2005 ICCAT Workshop on Methods to Reduce Mortality of Juvenile Tropical Tunas (Madrid, July 4 – 8, 2005)." In accordance with the Committee's current recommendation, any minimum size limit (or lack thereof) should be consistent for all species in a multi-species fishery. It follows that, since the minimum size limit for bigeye tuna has been eliminated, the minimum size limit for yellowfin tuna should likewise be eliminated. Notwithstanding this, the protection of juvenile tunas may be important and alternative approaches to accomplish this should be studied.

In 1993, ICCAT recommended "that there be no increase in the level of effective fishing effort exerted on Atlantic yellowfin tuna, over the level observed in 1992." As measured by fishing mortality estimates from the 2003 assessment, effective effort in 2001 appeared to be approaching or exceeding the 1992 levels. Since the relatively high catch levels of 2001 (159,000 t), catches have declined each year to a current level of 116,000 mt, a reduction of 27 percent. (Estimates of total yellowfin landings in 2002 and 2003, which were not available at the time of the assessment, are 139,000 mt and 124,000 mt, respectively). A potential explanation for this decline is the reduction in purse seine effort, but until a full assessment is conducted it is not possible to confirm this, since declines in nominal catch rates could suggest decreases in abundance or availability. Although the catches have been declining since 2001, as has the nominal effort of the purse seiners, the trend in effective effort is not clear.

Yellowfin tuna is listed as approaching an overfished condition by the United States. Several management measures have been implemented in the United States, consistent with ICCAT advice to limit fishing effort and to prevent overfishing. In 1999, NMFS implemented limited access in the pelagic longline fishery for Atlantic tunas, as well as a recreational retention limit for yellowfin tuna. The United States has also maintained its minimum size limit for YFT of 27" which was greater than that recommended by ICCAT before the organization repealed the recommendation.

Yellowfin tuna is the principal species of tropical tuna landed by U.S. fisheries in the western North Atlantic. Total estimated landings decreased to 6,500 mt in 2004, from the 2003 landings estimate of 7,702 mt. The 2004 estimate is considered provisional and may change owing to incorporation of late reports of commercial catches as they become available and to possible revisions in estimates of rod and reel catches made by recreational anglers. A high proportion of the estimated landings were due to rod and reel catches of recreational anglers in the NW Atlantic (3,434 mt). Estimates of U.S. recreational harvests for tuna and tuna-like species continue to be reviewed and this may result in the need to report additional revisions to the available estimates in the future.

*Recent and Ongoing Research*

In addition to the United States research findings for tropical tunas discussed above under bigeye tuna, one document was presented to the SCRS in 2005 that gave an overview of fishery trends and stock status for yellowfin tuna worldwide. It was noted that the natural mortality vector used by ICCAT in the Atlantic, while the same as that used by the IOTC for the Indian Ocean, is lower than is used by other scientific bodies for other oceans, particularly for the youngest ages. It was further noted that more recent information and methodologies may be available to potentially improve the estimates of natural mortality. Another document considered the estimation of natural mortality from multi-species tagging data. Due to limitations in the data (such as unbalanced design and different size distributions of released fish) and potential fishing differences between fleets, conclusions were limited to ratios of total mortality between fishing periods rather than any direct statement about natural mortality. Considering the importance of natural mortality estimates in the assessment of the stock, the improvement of natural mortality estimates remains a high research priority. It was noted that future stock assessments should include an evaluation of the sensitivity of results to the uncertainty in natural mortality estimates. Differences were also noted for other biological parameters used by the various scientific bodies, such as growth and maturity vectors, the extent to which these differences reflect estimation methodology, data quality, or real differences between stocks warrants investigation.

#### 3.2.3.3 Atlantic Albacore Tuna

*Life History and Species Biology*

Albacore is a temperate tuna widely distributed throughout the Atlantic Ocean and Mediterranean Sea. For assessment purposes, the existence of three stocks is assumed based on available biological information: northern and southern Atlantic stocks (separated at 5ºN), and a Mediterranean stock. Albacore spawning areas in the Atlantic are found in subtropical western areas of both hemispheres and throughout the Mediterranean Sea. Spawning takes place during austral and boreal spring-summer. Sexual maturity is considered to occur at about 90 cm FL (age five) in the Atlantic, and at smaller size (62 cm, age two) in the Mediterranean. Until this age, they are mainly found in surface waters, where they are targeted by surface gears. Some adult albacore are also caught using surface gears but, as a result of their deeper distribution, they are mainly caught using longlines. Young albacore tuna are also caught by longlines in temperate waters.

*Stock Status and Outlook*

The last assessment of the northern stock by ICCAT/SCRS was conducted in 2000, using data from 1975 to 1999, and that of the southern stock in 2003; no assessment of the Mediterranean stock has ever been carried out. To coordinate the timing of the assessments of northern and southern albacore tuna, the stock assessment for northern albacore was postponed at the 2004 ICCAT meeting from 2006 to 2007 (note the management measures for northern albacore expire at the end of 2006). The SCRS noted the considerable uncertainty that continues to remain in the catch-at-size data for the northern and southern stocks, and the profound impact this has had on attempts to complete a satisfactory assessment of northern albacore tuna.

<u>North Atlantic</u>

In 2003, the SCRS concluded that it was inappropriate to proceed with a VPA assessment based on the catch-at-age until the catch-at-size to catch-at-age transformation is reviewed and validated. In 2005, a document was presented on the analyses of catch-at-size and identifying the source of bias in the catch-at-age of the North Atlantic albacore stock. The SCRS recommends holding a data preparatory working group meeting to allow for a thorough revision of the North Atlantic stock prior to the next assessment in 2007. Consequently, the current state of the northern albacore stock is based primarily on the last assessment conducted in 2000 together with observations of CPUE and catch data provided to the SCRS in 2003. The results, obtained in 2000, showed consistency with those from previous assessments (Table 3.10).

The SCRS noted that CPUE trends have varied since the last assessment in 2000, and in particular differed between those representatives of the surface fleets (Spain Troll age two and Spain Troll age three) and those of the longline fleets of Japan, Chinese Taipei, and the United States. The Spanish age two troll series, while displaying an upward trend since the last assessment, nonetheless declined over the last ten years. For the Spanish age three troll series, the trend in the years since the last assessment is down; however, the trend for the remainder of the last decade is generally unchanged. For the longline fleets, the trend in CPUE indices is either upwards (Chinese Taipei and United States) or unchanged (Japan) in the period since the last assessment. However, variability associated with all of these catch rate estimates prevented definitive conclusions about recent trends of albacore catch rates.

Equilibrium yield analyses, carried out in 2000 and made on the basis of an estimated relationship between stock size and recruitment, indicate that spawning stock biomass was about 30 percent below that associated with MSY. However, the SCRS noted considerable uncertainties in these estimates of current biomass relative to the biomass associated with MSY ($B_{MSY}$), owing to the difficulty of estimating how recruitment might decline below historical levels of stock biomass. Thus, the SCRS concluded that the northern stock is probably below $B_{MSY}$, but the possibility that it is above it should not be dismissed (Figure 3.10). However, equilibrium yield-per-recruit analyses made by the SCRS in 2000 indicate that the northern stock is not being growth overfished ($F < Fmax$).

In terms of yield per recruit, the assessment carried out in 2000 indicates that the fishing intensity is at, or below, the fully exploited level. Concerning MSY-related quantities, the SCRS recalls that they are highly dependent on the specific choice of stock-recruitment relationship. The SCRS believed that using a particular form of stock-recruitment relationship that allows recruitment to increase with spawning stock size provided a reasonable view of reality. This hypothesis together with the results of the assessment conducted in 2000 indicate that the spawning stock biomass ($B_{1999}$) for the northern stock (29,000 mt) was about 30 percent below the biomass associated with MSY (42,300 mt) and that current F (2000) was about 10 percent above $F_{MSY}$. However, an alternative model allowing for more stable recruitment values in the range of observed SSB values would provide a lower estimate of SSB at MSY, below the current value.

South Atlantic

In 2003, an age-structured production model, using the same specifications as in 2000, was used to provide a base case assessment for southern Atlantic albacore. Results were similar to those obtained in 2000, but the confidence intervals were substantially narrower in 2003 than in 2000 (Table 3.11). In part, this may be a consequence of additional data now available, but the underlying causes need to be investigated further. The estimated MSY and replacement yield from the 2003 base case (30,915 mt and 29,256 mt, respectively) were similar to those estimated in 2000 (30,274 mt and 29,165 mt). In both 2000 and 2003, the fishing mortality rate was estimated to be about 60 percent of $F_{MSY}$. Spawning stock biomass has declined substantially relative to the late 1980s, but the decline appears to have leveled off in recent years and the estimate for 2002 remains well above the spawning stock biomass corresponding to MSY.

Catches of albacore in the South Atlantic in 2001 and 2002 were above replacement yield, and were below estimates of MSY in 2003. Nevertheless, both the 2000 and 2003 albacore assessments estimated that the stock is above $B_{MSY}$. There is now greater confidence in these estimates of MSY and therefore there is justification to base a TAC recommendation on MSY instead of replacement yield estimates from the model as in 2000. This results from the SCRS' view that current stock status is somewhat above $B_{MSY}$ and catch of this level, on average, would be expected to reduce the stock further towards $B_{MSY}$. Recent estimates of high recruitment could allow for some temporary increase in adult stock abundance under a 31,000 mt catch, but this result is uncertain.

Mediterranean

Given the lack of an assessment, the implications of the rapid increase in landings are unknown.

### *Effects of Regulations*

North Atlantic

In 2000, the SCRS recommended that in order to maintain a stable Spawning Stock Biomass in the near future the catch should not exceed 34,500 mt (the 1999 catch level) in the period 2001 – 2002. The SCRS further noted that should ICCAT wish the spawning stock biomass to begin increasing towards the level estimated to support MSY, and then catches in 2001 and 2002 should not exceed 31,000 mt. In 2004, the SCRS reiterated its previous advice and extended it until the next assessment in 2007. There is no ICCAT rebuilding plan for this species.

Since 2001, ICCAT established a TAC of 34,500 mt for this stock. In 2003, ICCAT extended this TAC through 2006. The SCRS noted that reported catches for 2001, 2002, 2003, and 2004 have been below the TAC. A 1998 recommendation that limits fishing capacity to the average of 1993 – 1995 also remains in force. The SCRS is unable to assess whether or not these recommendations have had a direct effect on the stock.

U.S. harvest of albacore tuna, based on 1997 through 2004 data, is landed primarily by rod and reel and pelagic longline fisheries in the Northwest Atlantic. Approximately 98 percent of total U.S. landings are harvested in the Northwest Atlantic. U.S. landings from the Caribbean increased in 1995 to make up over 14 percent of the total U.S. harvest of Albacore, but have since remained below four percent of the total.

Historically, albacore has not been a main focus of the U.S. commercial tuna fisheries operating in the North Atlantic. The commercial pelagic longline fishery harvests northern albacore tuna as incidental catch in the swordfish and other tuna pelagic fisheries. Reported commercial catches were relatively low prior to 1986; however, these catches increased substantially and have remained at higher levels throughout the 1990s. Commercial longline landings from the Northwest Atlantic over the past five years have ranged from a high of 172 mt in 2001 to a low of approximately 96 mt in 2003. In contrast, recreational estimates show a growing targeted albacore fishery off the United States Atlantic coast with landings increasing from approximately 122 mt in 2001 to over 500 mt in 2004. Calendar year landings vary between years by up to 30 percent for the longline fleet and by as high as a factor of four for the rod and reel fishery.

Since the ICCAT recommendation of a 607 mt TAC was implemented, total U.S. landings have been 453 mt (74 percent), 488 mt (80 percent), and 446 mt (73 percent) in 2001, 2002, and 2003 respectively. Calendar year landings for 2004 were 646 mt. These landings have been well below the annual TAC of 607 mt until 2004. The United States has annually taken less than two percent of the recorded total annual international landings (Table 3.6). In 2004, U.S. calendar year landings remained below the adjusted annual quotas. ICCAT recommendation provides for an adjusted TAC by adding the remaining balance from the previous year as carryover. The U.S. caught only 84 percent of the adjusted quota in 2004 and has a domestic adjusted quota in 2005 of 729 metric tons.

South Atlantic

Recent catches of albacore tuna in the South Atlantic are in the vicinity of the current and recent estimates of MSY (30,915 mt). Both the 2000 and the 2003 albacore assessments estimated that the stock is above $B_{MSY}$ (2003 estimates $B_{current}/B_{MSY} = 1.66$, $F_{current}/F_{MSY} = 0.62$). The SCRS recommends that in order to maintain SSB in the near future the catch should not exceed 31,000 mt until the next assessment in 2007.

Since 1999, ICCAT established the TAC for this stock (in 2001 – 2003, the TAC had been set at 29,200 mt). In 2003, ICCAT extended this TAC through 2004. The SCRS noted that reported catches have not exceeded the TAC in 2004. Also, the total catch by Chinese Taipei, South Africa, Brazil, and Namibia (26,620 mt) did not exceed the 27,500 mt catch limit of parties actively fishing for southern albacore, as stipulated by resolution 02-06. It should be noted that sufficient capacity exists within the fisheries to exceed the TAC as was done in 2000, 2001, and 2002. U.S. landings of South Atlantic Albacore over the past five years have been minimal (two or less mt / year). Japan adhered to its bycatch limit of four percent of the total catch of bigeye tuna in the Atlantic Ocean. However, the SCRS is unable to assess whether or not these catch limits have had a direct effect on the stock.

Mediterranean

There are no ICCAT management recommendations for the Mediterranean stock. However, the SCRS recommended to ICCAT that reliable data be provided on catch, effort and size for Mediterranean albacore tuna. The SCRS also recommended that an effort be made to recover historical data. Improvements to these basic inputs are essential before a stock assessment of Mediterranean albacore tuna can be attempted.

*Recent and Ongoing Research*

U.S. scientists prepared document SCRS/2005/081 which described population models for North Pacific albacore (*Thunnus alalunga*) that have been developed and reviewed within the North Pacific Albacore Workshop (NPALBW) forum since 2000. Currently, the NPALBW relies on a Virtual Population Analysis (VPA) model for the purposes of formulating an international-based consensus regarding the "status" of this fish stock. Recently, an equally important research directive from the NPALBW has been to develop alternative, more detailed statistical-based models, in efforts to evaluate more fully the relationship between this species' population dynamics and associated fishery operations (*i.e.*, areas of uncertainty in an overall stock assessment). Participants on the NPALBW developed one candidate model based on the Age-structured Assessment Program (ASAP), which generally represents a maximum likelihood-based numerical approach for conducting relatively straightforward, forward-simulation catch-at-age analyses. In addition, the document presents a brief discussion concerning development of other alternative stock assessment models, particularly length-based/age-structured platforms (*e.g.*, MULTIFAN-CL and Stock Synthesis 2).

#### 3.2.3.4 Atlantic Skipjack Tuna

*Life History and Species Biology*

Skipjack tuna is a gregarious species forming schools in the tropical and subtropical waters of the three oceans. Skipjack spawn opportunistically throughout the year in vast areas of the Atlantic Ocean. The size at first maturity is about 45 cm for males and about 42 cm for females in the East Atlantic, while in the West Atlantic sexual maturity is reached at around 51 cm for females and 52 cm for males. Skipjack growth is seasonal, with substantial differences according to the latitude. There remains considerable uncertainty about the variability of the growth parameters between areas. It is, therefore, a priority to gain more knowledge on the growth schemes of this species.

Skipjack is a species that is often associated with floating objects, both natural objects or fish aggregating devices (FADs) that have been used extensively since the early 1990s by purse seiners and baitboats (during the 1991 to 2003 period, about 55 percent of skipjack were caught with FADs). The concept of viscosity (low interchange between areas) could be appropriate for the skipjack stocks. A stock qualified as "viscous" can have the following characteristics:

- It may be possible to observe a decline in abundance for a local segment of the stock;
- Overfishing of that component may have little, if any, repercussion on the abundance of the stock in other areas; and,
- Only a minor proportion of fish may make large-scale migrations.

The increasing use of FADs could have changed the behavior of the schools and the migrations of this species. It is noted that, in effect, the free schools of mixed species were much more common prior to the introduction of FADs than now. These possible behavioral changes ("ecological trap" concept) may lead to changes in the biological parameters of this species as a result of the changes in the availability of food, predation, and fishing mortality. Skipjack caught with FADs are usually found associated with other species. The typical catch with floating objects is comprised of about 63 percent skipjack, 20 percent small yellowfin, and 17 percent juvenile bigeye and other small tunas. A comparison of size distributions of skipjack between periods prior to and after the introduction of FADs show that, in the eastern Atlantic, there has been an increase in the proportion of small fish in the catches, as well as a decline in the total catch in recent years in some areas.

The SCRS reviewed the current stock structure hypothesis that consists of two separate management units, one in the east Atlantic and another in the West Atlantic, separated at 30°W. The boundary of 30°W was established when the fisheries were coastal, whereas in recent years the East Atlantic fisheries have extended towards the west, surpassing this longitude, and showing the presence of juvenile skipjack tuna along the Equator, west of 30°W, following the drift of the FADs. This implies the potential existence of a certain degree of mixing. Nevertheless, taking into account the large distances between the east and west areas of the ocean, various environmental constraints, the existence of a spawning area in the east Atlantic as well as in the northern zone of the Brazilian fishery, and the lack of additional evidence (*e.g.,* transatlantic migrations in the tagging data), the hypothesis of separate east and west Atlantic stock is maintained as the most plausible alternative. On the other hand, in taking into account the biological characteristics of the species and the different fishing areas, smaller management units could be considered.

*Stock Status and Outlook*

The last ICCAT/SCRS assessment on Atlantic skipjack tuna was carried out in 1999 (Table 3.12). The state of the Atlantic skipjack stock(s), as well as the stocks of this species in other oceans, show a series of characteristics that make it extremely difficult to conduct an assessment using current models. Among these characteristics, the most noteworthy are:

- The continuous recruitment throughout the year, but heterogeneous in time and area, making it impossible to identify and monitor the individual cohorts;
- Apparent variable growth between areas, which makes it difficult to interpret the size distributions and their conversion to ages; and,
- Exploitation by many and diverse fishing fleets (baitboat and purse seine), having distinct and changing catchabilities, which makes it difficult to estimate the effective effort exerted on the stock in the East Atlantic.

For these reasons, no standardized assessments have been able to be carried out on the Atlantic skipjack stocks. Notwithstanding, some estimates were made by means of different indices of the fishery and some exploratory runs were conducted using a new development of the generalized production model.

<u>Western stock</u>

Standardized abundance indices up to 1998 were available from the Brazilian baitboat fishery and the Venezuelan purse seine fishery, and in both cases the indices seem to show a stable stock status. Uncertainties in the underlying assumptions for the analyses prevent the extracting of definitive conclusions regarding the state of the stock. However, the results suggest that there may be over-exploitation within the FAD fisheries, although it was not clear to what extent this applies to the entire stock. The SCRS could not determine if the effect of the FADs on the resource is only at the local level or if it had a broader impact, affecting the biology and behavior of the species. Under this supposition, maintaining high concentrations of FADs would reduce the productivity of the overall stock. However, since 1997, and due to the implementation of a voluntary Protection Plan for Atlantic tunas, agreed upon by the Spanish and French boat owners in the usual areas of fishing with objects, which later resulted in an ICCAT regulation on the surface fleets that practice this type of fishing, there has been a reduction in the skipjack tuna catches associated with FADs. Maintaining this closure would continue to have a positive effect on the resource. The development of nominal abundance indices of Brazilian baitboat fisheries and Venezuelan purse seiners, obtained up to 2004, seemed to show a stable stock status.

Eastern stock

Standardized catch rates are not available. However, an analysis was made, for the 1969 – 2002 period, of the different indices of the purse seine fishery that could provide valuable information on the state of the stock. For the majority of the indices, the trends were divergent, depending on the area, which may indicate the viscosity of the skipjack stock, with limited mixing rates between areas. Because of the difficulties in assigning ages to the skipjack catches, the estimates of the values of natural mortality by age and obtaining indices of abundance (especially for the eastern stock), no catch-by-age matrices were developed and, consequently, no analytical assessment methods were applied.

There is no quantified information available on the effective fishing effort exerted on skipjack tuna in the East Atlantic. It is supposed, however, that the increase in fishing power linked to the introduction to improved technologies on board the vessels as well as to the development of fishing under floating objects have resulted in an increase in the efficiency of the various fleets. An estimate of the increase in the coefficient of total mortality (Z) between the early 1980s and the end of the 1990s was carried out with a model using tagging data (Workshop on the mortality of juveniles in July 2005). For the range of sizes considered (about 40 – 60 cm FL), the increase in Z on the order of a factor 3 would reflect this increase in efficiency. This interpretation is supported by a comparison of skipjack size distributions in the East Atlantic between the periods prior to, and following, the use of FADs as an increase is observed in the proportion of small fish in the catches.

A document on the Spanish observer program on board purse seiners, presented during the 2005 SCRS, shows that for the 2001-2005 period the average rate of discards of skipjack tunas under FADs in the East Atlantic is estimated at 42 kg per ton of skipjack landed. In the West Atlantic, fishing effort of the Brazilian baitboats (which comprises the major skipjack fishery) decreased by half between 1985 and 1996, but seems to be stabilized since, after a slight increase.

| **Outlook** | *Unknown* |

### *Effects of Regulations*

There is currently no specific ICCAT regulation in effect for skipjack tuna. However, the French and Spanish boat owners voluntarily applied a moratorium on fishing under FADs for the period of November 1997 through January 1998, and November 1998 through January 1999. The moratorium, which was implemented in order to protect juvenile bigeye tuna, has had an influence on the skipjack catches made with FADs. Since 1999, a similar moratorium was applied, recommended by ICCAT, and is still in force. The average purse seine skipjack catches during the months from November to January by the fleets that applied the moratoria were reduced by 64 percent compared to the average catches between the 1993 – 1996 period (before the moratoria) and those corresponding to the 1998 – 2002 period. For the entire period in which the moratoria have been in effect (1998 – 2002), the average annual skipjack catches by the purse seine fleets that applied the moratoria decreased by 41 percent, which is equivalent to 42,000 mt per year. However, this decrease is likely a combined result of the decrease in effort and the moratorium impact; this is supported by the observation that the mean annual catch by boats has decreased only 18 percent between the two periods.

Total catches in 2004 in the Atlantic Ocean amounted to almost 161,000 mt which represents an increase of approximately 12.9 percent compared to the average of the last five years. Since the early 1990s, numerous changes in the fishery (such as the use the FADs and the expansion of the fishing area to the west) have increased skipjack catchability as well as the proportion of the skipjack stock which is exploited. At present, the major fisheries are the purse seine fisheries, particularly those of EC-Spain, EC-France, NEI, Ghana and Netherlands Antilles, followed by the baitboat fisheries of Ghana, EC-Spain and EC-France. The catches made in 2004 in the East Atlantic reached 134,000 mt, representing a 15.8 percent increase as compared to the average of 1999 – 2003. In the West Atlantic, the major fishery is the Brazilian baitboat fishery, followed by the Venezuelan purse seine fleet. The 2004 caches in the West Atlantic amounted to 26,900 mt, which is a level close to the average of the historical period in recent years.

Skipjack tuna are caught by U.S. vessels in the western North Atlantic. Total reported skipjack landings (preliminary) increased from 78 mt in 2003 to 102 mt in 2004. Almost 70 percent of U.S. landings are from recreational rod and reel catches and landings from the NW Atlantic and Caribbean areas, based on LPS statistical surveys of the U.S. recreational harvesting sector. Estimates of recreational harvests of skipjack continue to be reviewed and could be revised again in the future.

*Recent and Ongoing Research*

U.S. small tuna research is directed mainly on king and Spanish mackerel stocks, as the amount landed of other small tunas such by U.S. fishermen is generally low. The focus of research on skipjack research by the international scientific community is on basic stock structure and abundance and the influence of FADs on increase in efficiency of the various fleets. During the ICCAT Workshop on Methods to Reduce Mortality of Juvenile Tropical Tunas in July 2005 (Document SCI-032), a re-analysis on the tagging data in the Senegalese area showed however that the parameters of the skipjack growth curve obtained in this region were in fact closer to the growth estimates made in the Gulf of Guinea or in other oceans than those done previously in Senegal. In 2004 and 2005, U.S. scientists collaborated with Caribbean nations under the banner of the Caribbean Regional Fisheries Mechanism in initiating stock assessment analyses for small tuna (and other) stocks of mutual concern.

### 3.2.4 Atlantic Billfish

#### 3.2.4.1 Blue Marlin

*Life History/Species Biology*

Blue marlin (*Makaira nigricans*) range from Canada to Argentina in the western Atlantic, and from the Azores to South Africa in the eastern Atlantic. Blue marlin are large apex predators with an average weight of 100 – 175 kg (220 – 385 lb). Female blue marlin grow faster and reach a larger maximum size than males. Young blue marlin are one of the fastest growing teleosts, reaching 30 – 45 kg (66 – 99 lb) after the first year. The maximum growth rate of these fish is 1.66 cm/day (0.65 inches/day) which occurs at 39 cm LJFL (15.3 inches) (NMFS, 1999). Life expectancy for blue marlin is between 20 – 30 years based on age and growth analyses of dorsal spines.

Estimates of natural mortality rates for juvenile and adult billfish would be expected to be relatively low, generally in the range of 0.15 to 0.30, based on body size, behavior and physiology (NMFS, 1999). Sagitta otolith weight is suggested to be proportional to age, indicating that both sexes are equally long-lived, based on the maximum otolith weight observed for each sex. Predicting age from length or weight is imprecise due to many age classes in the fishery, and otoliths may provide a more accurate measure of age.

Blue marlin have an extensive geographical range, migratory patterns that include trans-Atlantic as well as trans-equatorial movements, and are generally considered to be a rare and solitary species relative to the schooling Scombrids (tunas). Graves et al. (2002) captured eight blue marlin with recreational fishing gear and then implanted fish with satellite pop-up tags. These fish moved 74 – 248 km (40–134 nautical miles (nm)) over five days, with a mean displacement of 166 km (90 nm). Fish spent the vast majority of their time in waters with temperatures between 22 and 26°C (71–78°F) and at depths less than 10 m. Prince et al. (2005) tagged one blue marlin with a PSAT tag off the coast of Punta Cana, Dominican Republic and found that this fish moved 406.2 km (219.3 nm) during a 40-d deployment (10.15 km/day (5.48 nm/day)). The maximum time at liberty recorded of a tagged individual was 4,024 days (about 11 years) for a blue marlin that was estimated to weigh 29.5 kg (65 lb) at the time of release. Junior et al. (2004) found the depth of capture for blue marlin with pelagic longline gear ranged from 50 – 190 m (164 – 623 feet), with most individuals captured at 90 m (295 feet).

The Cooperative Tagging Center (CTC) program has tagged 24,108 and recaptured over 220 blue marlin and found that these fish moved an average of 903 km (488 nm) (Ortiz et al., 2003). Some individuals have exhibited extended movement patterns, and strong seasonal patterns of movement of individuals between the United States and Venezuela are evident. A blue marlin released off Delaware and recovered off the island of Mauritius in the Indian Ocean represents the only documented inter-ocean movement of a highly migratory species in the history of the CTC. The minimum straight-line distance traveled for a blue marlin was 14,893 km (8,041 nm) and the maximum number of days at large was 4,024 d.

Adults are found primarily in the tropics within the 24°C (75°F) isotherm, and make seasonal movements related to changes in sea surface temperatures. In the northern Gulf of Mexico they are associated with the Loop Current, and are found in blue waters of low productivity rather than in more productive green waters. Off of Puerto Rico, the largest numbers of blue marlin are caught during August, September, and October. Equal numbers of both sexes occur off northwest Puerto Rico in July and August, with larger males found there in May and smaller males in September. Very large individuals, probably females, are found off the southern coast of Jamaica in the summer and off the northern coast in winter, where males are caught in December and January.

There has not been an Atlantic wide survey of spawning activity for blue marlin, however, these fish generally reproduce between the ages of two and four, at 220 – 230 cm (86 – 90 inches) in length, and weigh approximately 120 kg (264 lb). Female blue marlin begin to mature at approximately 47 – 60 kg (104 – 134 lb), while males mature at smaller weights, generally from 35 – 44 kg (77 – 97 lb). There are likely two separate spawning events that occur at different times in the North and South Atlantic. South Atlantic spawning takes place between February and March (NMFS, 1999). Peak spawning activity in the North Atlantic Ocean occurs between July and October, with females capable of spawning up to four times per reproductive season (de Sylva and Breder, 1997). Prince et al. (2005) conducted 23 neuston tows in the vicinity of Punta Cana, Dominican Republic between 23 April and 17 May and successfully identified four larval blue marlin; the size of the larvae indicated that spawning activity was taking place in the same general area where these samples were conducted. Serafy et al. (2003) identified 90 blue marlin larvae in the vicinity of Exuma Sound, Bahamas in the month of July, indicating that spawning activity had taken place 18 days prior to sampling.

During the spawning season, blue marlin release between one and eleven million small (1 – 2 mm), transparent pelagic planktonic eggs. The number of eggs has been correlated to interspecific sizes among billfish and the size of individuals within the same species. Ovaries from a 147 kg (324 lb) female blue marlin from the northwest Atlantic Ocean were estimated to contain 10.9 million eggs, while ovaries of a 125 kg (275 lb) female were estimated to contain seven million eggs. Males are capable of spawning at any time.

Blue marlin are generalist predators feeding primarily on epipelagic fish and cephalopods in coastal and oceanic waters, however, mesopelagic fish and crustaceans associated with rocky, sandy, and reef bottoms are also important components of the diet. Feeding in mesopelagic areas probably takes place at night (Rosas-Alayola et al., 2002). Diet studies of blue marlin off the northeastern coast of Brazil indicate that oceanic pomfret (*Brama brama*) and squid (*Ornithoteuthis antillarum*) were the main prey items and present in at least 50 percent of stomachs. Other important prey species vary by location and include dolphin fishes, bullet tuna (*Auxis. spp*) around the Bahamas, Puerto Rico, and Jamaica, and dolphin fishes and scombrids in the Gulf of Mexico. Stomach contents have also included deep-sea fishes such as chiasmodontids.

Constant ingestion of small quantities of food is necessary. Blue marlin have relatively small stomachs, reducing the proportion of the body allocated for visceral mass, and allocating more volume to musculature for swimming speed and endurance (Junior *et al*., 2004). In the Pacific Ocean, changes in the diet observed are related more with abundance and distribution of prey than preferences in food items, with *Auxis* spp. (bullet and frigate tunas) well represented in all locations. Predators of blue marlin are relatively unknown. Sharks will attack hooked blue marlin, but it is not known if they attack free-swimming, healthy individuals.

*Stock Status and Outlook*

Since 1995, blue marlin have been managed under a single stock hypothesis because of tagging data and mitochondrial DNA evidence that are consistent with one Atlantic-wide stock. The last stock assessment for blue marlin was in 2000 using similar methods to the previous assessment (1996), however, data was revised in response to concerns raised since the 1996 assessment. The assessment reflects a retrospective pattern wherein improvement in estimated biomass ratios result in estimated lower productivity. The 2000 assessment was slightly more optimistic than the 1996 assessment. Atlantic blue marlin are at approximately 40 percent of $B_{MSY}$ and overfishing has taken place for the last 10 – 15 years. $B_{MSY}$ is estimated at 2,000 mt (4,409,245 lb) and current fishing mortality is approximately four times higher than $F_{MSY}$ (Table 3.13) (SCRS, 2005). There is uncertainty in the assessment because the historical data is not well quantified. The 2000 assessment estimated that overfishing was still occurring and that productivity (MSY and a stock's capacity to replenish) was lower than previously estimated. Therefore, it is expected that landings in excess of estimated replacement yield would result in further stock decline (SCRS, 2005).

No additional assessment information became available in 2005 to modify recommendations currently in force. The current assessment indicates that the stock is unlikely to recover if the landings contemplated by the 1996 ICCAT recommendation continue into the future. While there is additional uncertainty in stock status and replacement yield, estimates are not reflected in bootstrap results, these uncertainties can only be addressed through substantial investment in research into habitat requirements of blue marlin and further verification of historical data. The SCRS recommended that the ICCAT take steps to reduce the catch of blue marlin as much as possible, including: reductions in fleet-wide effort, a better estimation of dead discards, establishment of time area closures, and scientific observer sampling for verification of logbook data. The SCRS noted that future evaluation of management measures relative to the recovery of the blue marlin stock are unlikely to be productive unless new quantitative information on the biology and catch statistics of blue marlin, and additional years of data are available (SCRS, 2004 and 2005).

A summary of Atlantic blue marlin stock assessment data can be found in Table 3.13. Estimated catches of Atlantic blue marlin by region for the period 1956 – 2001 can be found in Figure 3.11. A composite CPUE series for blue marlin for the period 1955 – 2000 can be found in Figure 3.12. The estimated median relative fishing mortality trajectory for Atlantic blue marlin can be found in Figure 3.13. A stock assessment for blue marlin is scheduled for 2006.

**Table 3.13 Summary of Atlantic Blue Marlin Stock Assessment data. Weights are in metric tons, whole weight.** Source: SCRS, 2005.

| ATLANTIC BLUE MARLIN SUMMARY[1] | |
|---|---|
| | **Total Atlantic** |
| Maximum Sustainable Yield (MSY) | ~ 2,000 t (~ 1,000 ~ 2,400 t)[2] |
| 2002 Yield | 2,626 t |
| 2003 Yield | 2,713 t |
| 2004 Yield[4] | 2,076 t |
| 1999 Replacement Yield | ~ 1,200 t (~ 840 - 1,600 t)[2] |
| Relative Biomass ($B_{2000}/B_{MSY}$) | ~ 0.4 (~ 0.25 - 0.6)[2] |
| Relative Fishing Mortality ($F_{1999}/F_{MSY}$) | 4.0 (~ 2.5 - 6.0)[2] |
| Management Measures in Effect | - Reduced pelagic longline and purse seine landings to 50% of 1996 or 1999 levels, whichever is greater [Recs. 00-13[3], 01-10[3] and 02-13]. |

[1] Assessment results are uncertain. Uncertainty in these estimates is not fully quantified by bootstrapping.
[2] Approximate 80% CI from bootstrap for ASPIC model.
[3] These measures did not take effect until mid-2001.
[4] Reported Task I value, which is likely to be a substantial underestimate of the total catch.

*Effect of Regulations*

ICCAT Management Recommendations

ICCAT Recommendation 97-09 required Contracting Parties to reduce, starting in 1998, blue marlin and white marlin landings by at least 25 percent for each species from 1996 landings, by the end of 1999. Recommendations 00-13, 01-10, 02-13, and 04-09 imposed or extended additional catch restrictions for blue marlin. These included limiting the annual amount of blue marlin that can be harvested by pelagic longline and purse seine vessels and retained for landing to no more than 50 percent of the 1996 or 1999 landing levels, whichever is greater, as well as requiring that all blue marlin and white marlin brought to pelagic longline and purse seine vessels alive be released in a manner that maximizes their survival. The live release provision does not apply to marlins that are dead when brought along the side of the vessel or that are not sold or entered into commerce (SCRS, 2004). Globally, catches of blue marlin appear to have been reduced as a result of ICCAT recommendations, which tied reductions in blue marlin landings to 1996 or 1999 levels, whichever was greater. Total Atlantic-wide catches of blue marlin, as reported to ICCAT, decreased by approximately 46 percent from 3,836 mt in 1999 to 2,076 mt in 2004. Total Atlantic-wide longline landings of blue marlin, as reported to ICCAT, decreased by approximately 41 percent from 2,276 mt in 1999 to 1,343 in 2004.

In addition, these recommendations limited recreational landings in the United States to 250 blue and white marlin combined, on an annual basis. Also in 2000, ICCAT recommended that a blue marlin minimum size be established for recreational fisheries (251 cm (98.8 inches) LJFL). Most recently, ICCAT recommendation 04-09, extended phase one of the ICCAT mortality reduction plan, as established and modified by recommendations 00-13, 01-10, 02-13, through 2006 and postponed the next scheduled assessment of Atlantic blue marlin until 2006. The SCRS noted that it does not expect to have enough new information to provide an assessment of these recent regulations until 2006.

Domestic Regulations

The U.S. Atlantic billfish fishery, including blue marlin, white marlin, sailfish, and spearfish, has been reserved as a recreational fishery through domestic regulation since 1988. Possession of Atlantic billfish is prohibited by U.S. pelagic longline vessels and no sales of Atlantic billfish are allowed. Data on bycatch of Atlantic billfish in the domestic Atlantic pelagic longline fishery can be found in Section 3.4.1 and Appendix C. The recreational fishery is an open access fishery. Anglers must possess either a HMS Angling category permit or a CHB category permit to possess a billfish. General category tuna permit holders may possess Atlantic billfish only when participating in a registered HMS tournament. Details of the permitting program, including the number of permit holders can be found in Section 3.9. Data on domestic recreational catches of Atlantic billfish are obtained from a combination of sources, including: the Recreational Billfish Survey; the HMS swordfish and billfish non-tournament reporting line; MRFSS, and LPS. U.S. recreational billfish landings can be seen in section 4.2.3 of this document. The U.S. implemented a minimum legal size of 251 cm (99 inches), 167 cm (66 inches), 160 cm (63 inches) for blue marlin, white marlin, and sailfish respectively, in 1999.

Possession of Atlantic longbill spearfish have been prohibited since 1988. Rod and reel is the only type of gear authorized in the domestic billfish fishery.

*Recent and Ongoing Research*

The NMFS SEFSC played a substantial role in the ICCAT Enhanced Research Program for Billfish in 2004, with SEFSC scientists acting as the coordinator for the western Atlantic Ocean. Major accomplishments in the western Atlantic in 2004 were documented in SCRS/04/028. Highlights include 11 at-sea sampling trips with observers on Venezuelan industrial longline vessels in September 2004. Of the trips accomplished to date, 4 observer trips were on Korean type vessels fishing under the Venezuelan flag. Most of these vessels are based out of Cumana targeting tuna, swordfish, or both at the same time. Biological sampling of swordfish, Istiophorids, and yellowfin tuna for reproductive and age determination studies, as well as genetics research were continued during the 2004 sampling season. Shore-based sampling of billfish landings for size frequency data, as well as tournament sampling was obtained from Venezuela, Grenada, U.S. Virgin Islands, Bermuda, Barbados, and Turks and Caicos Islands. Program participants in Venezuela, Grenada, and Barbados continued to assist in obtaining information on tag-recaptured billfish, as well as numerous sharks, in the western Atlantic Ocean during 2004; a total of 44 tag recovered billfish and sharks were submitted to the Program Coordinator in 2004. Age, growth, and reproductive samples from several very large billfish were also obtained during 2004.

A study conducted by the Virginia Institute of Marine Science (VIMS) to evaluate post release survival and habitat use from the recreational fishery for Atlantic white marlin using pop-up satellite archival tags (PSATs) was finalized in 2004 and published in the peer review literature. A separate study conducted by VIMS on U.S. longline vessels to evaluate post release survival of marlin, as well as evaluating hook performance and related mortality was also finalized in 2004. These data have been submitted to a peer reviewed journal and are currently under review. The SEFSC has conducted several studies in the Northwest Atlantic and the Pacific coast of Central America to evaluate habitat use and reproductive biology of billfish using PSAT technology. About 200 PSATs have been deployed in this effort over the last 4 years with deployments ranging from a month to 5.5 months. Several peer reviewed papers summarizing these results are in press at this time, while other papers are currently in preparation. In addition, SEFSC is also currently conducting pelagic longline research to evaluate gear behavior, and the effects of gear modification on catch rate and survival of target and non-target species. Three cruises have been completed to date. This work in ongoing and should be finished sometime in 2006. Cooperative billfish research between US and Brazilian scientists was initiated in 2005.

The Fishery Management Group of the University of Miami is carrying out research on Atlantic billfish on three areas, population parameter estimation, population modeling and development of socio-economic indicators. Others at the University of Miami's Rosenstiel School and elsewhere are conducting research on early life history, reproductive biology and ecology of billfishes, as well as age and growth estimation.

Updates of standardized CPUE for blue and white marlin from the United States pelagic longline fishery in the NW Atlantic and Gulf of Mexico and the U.S. recreational tournament fishery in the NW Atlantic and Gulf of Mexico were developed and presented to ICCAT in 2005 (Document SCRS/2005/30 and SCRS/2005/31). Numerous additional papers were presented regarding standardization of CPUEs. Please see http//:www.iccat.es for additional information.

Multiple papers on habitat use were submitted to the ICCAT SCRS in 2005. These included papers on: vertical habitat use of white marlin in numerous locations of the western North Atlantic using PSAT tags (SCRS/2005/034); the depth distributions of 52 blue marlin in relation to exposure to longline gear using PSAT tags (SCRS/2005/035); and, a quantitative framework and numerical method for characterizing vertical habitat use by large pelagic animals using pop-up satellite tag data (SCRS/2005/). Additional information on spawning area research and other topics can be found at http//:www.iccat.es.

#### 3.2.4.2 White Marlin

*Life History/Species Biology*

White marlin (*Tetrapturus albidus*) are found exclusively in tropical and temperate waters of the Atlantic Ocean and adjacent seas, unlike sailfish and blue marlin, which are also found in the Pacific Ocean. White marlin are found at the higher latitudes of their range only in the warmer months. Junior et al. (2004) captured white marlin with pelagic longline gear off northeastern Brazil in depths ranging from 50 – 230 m (164 – 754 feet), with no obvious depth layer preference. White marlin generally prefer water temperatures above 22°C (71° F) with salinities between 35 – 37 ppt (NMFS, 1999). They may occur in small, same-age schools, however, are generally solitary compared to the Scombrids (tunas). Catches in some areas may include a rare species (*Tetrapturus georgei*) which is superficially similar to white marlin. The so-called "hatchet marlin" may also represent (*T. georgei)*, and has been caught occasionally in the Gulf of Mexico and South Atlantic (NMFS, 1999).

White marlin are generally 20 – 30 kg (44 – 66 lb) at harvest. These fish grow quickly, with females attaining a larger maximum size than males, and have a life span of 18 years (SCRS 2004). Adult white marlin grow to over 280 cm (110 inches) TL and 82 kg (184 lb). White marlin exhibit sexually dimorphic growth patterns; females grow larger than males, but the dimorphic growth differences are not as extreme as noted for blue marlin. This species undergoes extensive movements, although not as extreme as those of the bluefin tuna and albacore. Trans-equatorial movements have not been documented for the species. There have been 31,483 white marlin tagged and released by the CTC program, with 577 reported recaptures (1.83 percent of all releases) (Ortiz et al., 2003). The majority of releases took place in the months of July through September, in the western Atlantic off the east coast of the United States. Releases of tagged white marlin also occurred off Venezuela, in the Gulf of Mexico, and in the central west Atlantic. The longest distance traveled is 6,517 km (4,049 miles) and the maximum days at large is 5,488 days (approx. 15 years). A substantial number of individuals moved between the Mid-Atlantic coast of the United States and the northeast coast of South America. Overall, 1.1 percent of documented white marlin recaptures have made trans-Atlantic movements. The longest movement was for a white marlin tagged during July 1995 off the east coast near Cape May, NJ and recaptured off Sierra Leone, West Africa, in November, 1996. The fish traveled a distance of at least 6,517 km (3,519 nm) over 476 days (NMFS, 1999). Prince et al. (2005) tagged six white marlin off the coast of Punta Cana, Dominican Republic and found their displacement to be between 58.7 and 495.8 km (31.7 – 267.7 nm), ranging from 2.1 – 13.3 km/day (mean = 6.3 km/day).

White marlin spawn in the spring (March through June) in the northwestern Atlantic Ocean and females are generally 20 kg (44 lb) in mass and 130 cm (51.2 inches) in length at sexual maturity. White marlin spawn in tropical and sub-tropical waters with relatively high surface temperatures and salinities (20 – 29°C (68 – 84°F) and over 35 ppt) and move to higher latitudes during the summer. There has not been an Atlantic-wide study of the spawning behavior of white marlin. Spawning seems to take place in more offshore areas than for sailfish, although larvae are not found as far offshore as blue marlin. Females may spawn up to four times per spawning season (de Sylva and Breder, 1997). It is believed there are at least three spawning areas in the western north Atlantic: northeast of Little Bahama Bank off the Abaco Islands; northwest of Grand Bahama Island; and southwest of Bermuda. Prince et al. (2005) found eight white marlin larvae in neuston tows in April/May off the coast of Punta Cana, Dominican Republic indicating that there had been recent spawning activity in this general area. Larvae have also been collected from November to April, but these may have been sailfish larvae (*Istiophorus platypterus*), as the two can not readily be distinguished (NMFS, 1999). Spawning concentrations occur off the Bahamas, Cuba, and the Greater Antilles, probably beyond the U.S. EEZ, although the locations are unconfirmed. Concentrations of white marlin in the northern Gulf of Mexico and from Cape Hatteras, NC to Cape Cod, MA are probably related to feeding rather than spawning (NMFS, 1999).

White marlin are primarily piscivorous. Oceanic pomfret and squid were the most important food items in a study that sampled stomachs collected off the coast of Brazil in the southwestern Atlantic Ocean (Junior et al., 2004). The number of food items per stomach ranged from 1 – 12 individuals. The largest prey observed in white marlin stomachs were snake mackerel (*Gempylus serpens*), that were 40 – 73 cm (15.7 – 28.7 inches) in length (Junior et al., 2004). Squid, dolphin, hardtail jack, flying fish, bonitos, mackerels, barracuda, and puffer fish are the most important prey items in the Gulf of Mexico.

Data from a large sport fishery for white marlin that occurs during the summer between Cape Hatteras, NC and Cape Cod, MA indicates that white marlin inhabit offshore (148 km (80 nm)) submarine canyons, extending from Norfolk Canyon in the Mid-Atlantic to Block Canyon off eastern Long Island. Concentrations of white marlin are associated with rip currents and weed lines (fronts), and with bottom features such as steep drop-offs, submarine canyons, and shoals. Sport fishing for white marlin also occurs in the Straits of Florida, southeast Florida, the Bahamas, and off the north coasts of Puerto Rico and the Virgin Islands. Summer concentrations in the Gulf of Mexico are found off the Mississippi River Delta and at DeSoto Canyon, with a peak off the delta in July, and in the vicinity of DeSoto Canyon in August. In the Gulf of Mexico, adults appear to be associated with blue waters of low productivity, being found with less frequency in more productive green waters. While this is also true of the blue marlin, there appears to be a contrast between the factors controlling blue and white marlin abundance, as higher numbers of blue marlin are generally caught when catches of white marlin are low, and vice versa. It is believed that white marlin prefer slightly cooler temperatures than blue marlin.

*Stock Status and Outlook*

White marlin have been managed under a single stock hypothesis by ICCAT since 2000. The most recent stock assessments for white marlin (1996, 2000, and 2002) all indicated that biomass of white marlin has been below $B_{MSY}$ for more than two decades and the stock is overfished. In 2004, the SCRS indicated that in spite of significant improvements in the relative abundance estimates made available during the last three assessments, they are still not informative enough to provide an accurate estimate of stock status (SCRS, 2004). The 2002 assessment indicated that the relative fishing mortality is 8.28 times that permissible at $F_{MSY}$ (Table 3.14). Given that the stock is severely depressed, the SCRS concluded that ICCAT should take steps to reduce the catch of white marlin as much as possible, first by increasing observer coverage to improve estimates of catch and dead discards of white marlin. Furthermore, SCRS recommended that Contracting Parties conduct research into habitat requirements and post-release survival of white marlin and take steps to verify historical fishery data.

The SCRS suggested that ICCAT take steps to make sure that the intended reductions in catch are complied with, and monitored, so that proper evaluation can be carried out in the future. The SCRS recommended improving observer programs so that better estimates of catch and dead discards of white marlin are obtained. The SCRS further recommended that, in the absence of observing a change in population status resulting from the most recent management measures, the potential for increasing stock size of white marlin may require future catches to be reduced beyond the level apparently intended by its most recent recommendations. However, the SCRS also stated that more definitive advice should be available after several years of data become available. The SCRS also noted that future evaluation of management measures relative to the recovery of the white marlin stock is unlikely to be productive unless new quantitative information on the biology and catch statistics of white marlin, and additional years of data, are available (SCRS, 2004). As such, ICCAT postponed the next white marlin assessment until 2006. A summary of Atlantic white marlin stock assessment data can be found in Table 3.14.

New standardized catch rate information was presented in 2005, updating catch rates from U.S. recreational fisheries in the northwest Atlantic and Gulf of Mexico and the Venezuelan longline and artesinal fisheries. In spite of the progress made, the SCRS can not interpret the historic CPUE trends for white marlin (SCRS, 2005). In 2002, an ESA listing review was completed by NMFS. NMFS determined that listing Atlantic white marlin under the Endangered Species Act was not warranted at that time. NMFS has committed to conducting another ESA listing review in 2007.

**Table 3.14** **Summary of Atlantic White Marlin Stock Assessment data. Weights are in metric tons, whole weight.** Source: SCRS, 2005.

| ATLANTIC WHITE MARLIN SUMMARY[1] | | | | |
|---|---|---|---|---|
| | *Likely value* | *Continuity case[2] estimate (80% conf. limit)* | *Retrospective adjusted estimate[3]* | *Range of sensitivity[4] estimates* |
| Maximum Sustainable Yield | Below 2000 Yield | 964 t (849-1070) | | 323-1,320 t |
| 2002 Yield | 822 t | -- | | -- |
| 2003 Yield | 615 t | -- | | -- |
| 2004 Yield[5] | 532 t | | | |
| 2001 Replacement Yield | Below 2000 Yield | 222 t (101-416) | 371 t | 102-602 t |
| Relative Biomass ($B_{2001}/B_{MSY}$) | <1 (Over-fished) | 0.12 (0.06-0.25) | 0.22 | 0.12-1.76 |
| Relative Fishing Mortality ($F_{2000}/F_{MSY}$) | >1 (Over-fishing) | 8.28 (4.5-15.8) | 5.05 | 0.80-10.30 |
| Management Measures in Effect: | - In 2001 and 2002, PS and LL fisheries limit landings to 33% of max (1996, 1999) level. [Rec. 00-13], [Rec. 01-10] and [Rec. 02-13]. | | | |

1 Assessment results are highly uncertain.
2 The data used are not sufficiently informative to choose a "best case". For consistency, the continuity case presented here is based on data and assumptions that closely resemble the analyses made in 2000. Confidence limits from bootstrapping are conditional on this model-data set and thus may underestimate the real uncertainty.
3 These results are for the continuity case except that they were adjusted for retrospective biases.
4 The sensitivity analyses made were not chosen in a systematic way; the range is presented only for qualitative guidance.
5 Reported Task I value for 2004, which is likely an underestimate of total catch.

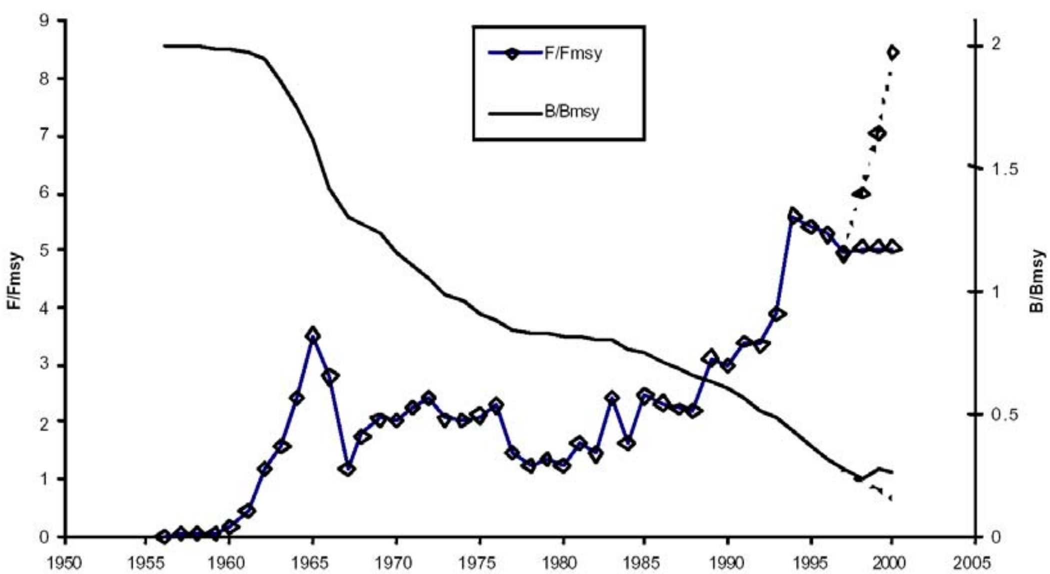

**Figure 3.16** **Estimated biomass ratio $B_{2000}$/ $B_{MSY}$ (solid line, no symbols) and fishing mortality ratio F2000/FMSY (solid line with symbols) from the production model fitted to the continuity case for white marlin. Ratios of last three years have been adjusted for retrospective pattern. Broken lines show unadjusted ratios. Note that scales are different for each ratio.** Source: SCRS, 2004.

*Effect of Regulations*

ICCAT Management Recommendations

Recommendation 97-09 required ICCAT Contracting Parties to reduce, starting in 1998, blue marlin and white marlin landings by at least 25 percent for each species from 1996 landings, such reduction to be accomplished by the end of 1999. ICCAT Recommendations 00-13, 01-10, and 02-13 imposed or extended additional catch restrictions for white marlin. These included reductions to no more than 33 percent of the 1996 or 1999 landing levels, whichever is greater, in the annual amount of white marlin that can be harvested and retained for landing by pelagic longline and purse seine vessels. Further, all blue marlin and white marlin brought to pelagic longline and purse seine vessels alive are required to be released in a manner that maximizes their survival (SCRS, 2004). Post-release survival studies concluded that white marlin can generally survive the trauma of being captured on pelagic longline gear (SCRS, 2005) and suggest that current management practices requiring the release of live white marlin (Rec. 00-13) will reduce fishing mortality on the stock. The live release provision does not apply to marlins that are dead when brought along the side of the vessel or that are not sold or entered into commerce. While the stock status evaluations are uncertain, projections indicated that the apparent intent of the ICCAT Billfish recommendations has, in the short term, some potential for stabilizing the stock biomass near current levels. Since 2000 is the last year of data used for the last stock assessment, it is too early to evaluate the effect of these recommendations on the stock. A stock assessment for white marlin is scheduled for 2006.

Globally, catches of white marlin appear to have been reduced as a result of ICCAT recommendations to less than 1,000 mt since 2000. Preliminary catches for 2004 were 532 mt, a slight decrease from 2003. Reported catches in 2004 by Brazil are lower than in previous years as a result of the implementation of the ICCAT recommendation to release live marlins, increased observer coverage, and a reduction in longline fishing effort (SCRS, 2005). Total Atlantic-wide catches of white marlin, as reported to ICCAT, decreased by approximately 48 percent from 1,028 mt in 1999 to 532 mt in 2004. Total Atlantic-wide longline landings of white marlin, as reported to ICCAT, decreased by approximately 46 percent from 924 mt in 1999 to 501 mt in 2004. Purse seine fisheries have incidental catches of white marlin, especially those that set on FADs. A temporary ban on FADs implemented by the EU resulted in a 300 – 400 mt (661,386 – 881,849 lb) decrease in incidental purse seine catches of all marlins (Gaertner et al., 2002). In the United States, white marlin are managed exclusively for recreational fisheries. This fishery is subject to an ICCAT imposed, 250-fish limit, annually for both blue and white marlin combined. In 2005, 31 recreationally landed white marlin were reported to ICCAT by the United States. In 2001, time area closures were established in the United States to reduce interactions between longline fisheries and white marlin and other billfish.

Domestic Regulations

Please see the discussion of domestic regulations contained in section 3.2.4.1, above.

*Recent and Ongoing Research*

Please see the discussion of recent and ongoing research contained in section 3.2.4.1, above.

### 3.2.4.3 Sailfish

*Life History/Species Biology*

Sailfish have a pan-tropical distribution and prefer water temperatures between 21 and 28°C (69 – 82°F). Although sailfish are the least oceanic of the Atlantic billfish and have higher concentrations in coastal waters (more than any other Istiophorid), they are also found in offshore waters. They range from 40°N to 40°S in the western Atlantic and 50°N to 32°S in the eastern Atlantic. No trans-Atlantic movements have been recorded, suggesting a lack of mixing between east and west. Although sailfish are generally considered to be rare and solitary species relative to the schooling Scombrids, sailfish are known to occur along tropical coastal waters in small groups consisting of at least a dozen individuals. Junior et al. (2004) captured sailfish in the southwestern Atlantic Ocean with pelagic longline gear at depths between 50 – 210 m (164 – 688 feet), with most individuals captured at 50 m. Sailfish are the most common representative of the Atlantic Istiophorids in U.S. waters (SCRS, 2005). Female sailfish grow faster, and attain a larger maximum size, than males while both sexes have a life expectancy of 15 years (NMFS, 1999).

In the winter, sailfish are found in schools around the Florida Keys and eastern Florida, in the Caribbean, and in offshore waters throughout the Gulf of Mexico. In the summer, they appear to migrate northward along the U.S. coast as far north as the coast of Maine, although there is a population off the east coast of Florida year-round. During the summer, some of these fish move north along the inside edge of the Gulf Stream. In the winter, they regroup off the east coast of Florida. Sailfish appear to spend most of their time above the thermocline, which occurs at depths of 10 – 20 m (32.8 – 65.6 feet) and 200 – 250 m (656 – 820 feet), depending on location. The 28°C (82°F) isotherm appears to be the optimal temperature for this species. Sailfish are mainly oceanic but migrate into shallow coastal waters. Larvae are associated with the warm waters of the Gulf Stream (NMFS, 1999).

A total of 65,868 sailfish have been tagged and released through the efforts of the CTC program, with reported recapture of 1,204 sailfish (1.83 percent of all releases). Most releases occurred off southeast Florida, from north Florida to the Carolinas, the Gulf of Mexico, Venezuela, Mexico, the northern Bahamas and the U.S. Virgin Islands. One tagged and recaptured specimen traveled from Juno, FL to the Mid-Atlantic, a distance of 2,972 km (1,745 miles). The longest movement tracked by tagging was 3,861 km (2,084 miles) and the longest time at large was 6,658 days (18.2 years) (Ortiz et al., 2003). During the winter, sailfish are restricted to the warmer parts of their range and move farther from the tropics during the summer. The summer distribution of sailfish does not extend as far north as for marlins, especially white marlin. Tag-and-recapture efforts have recovered specimens only as far north as Cape Hatteras, NC. Few trans-Atlantic or trans-equatorial movements have been documented using tag-recapture methods (NMFS, 1999).

Most sailfish examined that have been caught off Florida are under three years of age. Mortality is estimated to be high in this area, as most of the population consists of only two year classes. The longest period a recaptured-tagged animal was found to be at-large was 16.1 years. Unfortunately, the size at release is not available for this fish. Growth rate in older individuals is very slow (0.59 kg/yr (1.3 lb/year). Sailfish are probably the slowest growing of the Atlantic istiophorids. Sexual dimorphic growth is found in sailfish, but it is not as extreme as with blue marlin (NMFS, 1999).

Female sailfish spawn at age three and are generally 13 – 18 kg and 157 cm (28.6 – 39.6 lb and 61.8 inches), whereas males generally mature earlier at 10 kg and 140 cm (22 lb and 55.1 inches). Spawning takes place between April and October (de Sylva and Breder, 1997). Spawning has been reported to occur in shallow waters 9 – 12 m (30 – 40 ft) around Florida, from the Florida Keys to the region off Palm Beach on the east coast. Spawning is also assumed to occur, based on presence of larvae, offshore beyond the 100 m (328 feet) isobath from Cuba to the Carolinas, from April to September. However, these spawning activities have not been observed. Sailfish can spawn multiple times in one year, with spawning activity-moving northward in the western Atlantic as the summer progresses. Larvae are found in Gulf Stream waters in the western Atlantic, and in offshore waters throughout the Gulf of Mexico from March to October (NMFS, 1999). Serafy et al. (2003) found three larval sailfish in Exuma Sound, Bahamas, in the month of July indicating that there had been recent spawning activity in this vicinity. In the Pacific Ocean, sailfish spawn in waters between 27 – 30°C (Hernandez-H and Ramirez-H, 1998).

Sailfish are generally piscivorous, but also consume squid. Larvae eat copepods early in life then switch to fish at 6.0 mm (0.2 inches) in length (NMFS, 1999). The diet of adult sailfish caught around Florida consists mainly of pelagic fishes such as little tunny (*Euthynnus alletteratus*), halfbeaks (*Hemiramphus* spp.), cutlassfish (*Trichiurus lepturus*), rudderfish (*Strongylura notatus*), jacks (*Caranx* spp.), pinfish (*Lagodon rhomboides*), and squids (*Argonauta argo* and *Ommastrephes bartrami)*. Sailfish are opportunistic feeders and there is evidence that they may feed on demersal species such as sea robin (*Triglidae*), cephalopods and gastropods found in deep water.

Sailfish collected in the western Gulf of Mexico contained a large proportion of shrimp in their stomachs in addition to little tunny, bullet tuna (*Auxis* spp.), squid, and Atlantic moonfish (*Vomer setapinnis*). Junior et al. (2004) determined that squid were actually the second most important food item in the southwestern Atlantic off the coast of Brazil. Number of food items per stomach ranged from 1-14, and 6 percent of the stomachs were empty upon collection (Junior *et al*., 2004). Adult sailfish are probably not preyed upon often, but predators include killer whales (*Orcinus orca*), bottlenose dolphin (*Tursiops turncatus*), and sharks.

Participants from many nations target sailfish in both the western and eastern Atlantic Ocean.  Sailfish are found predominantly in the upper reaches of the water column and are caught in directed sport fisheries (recreational) and as bycatch in the offshore longline fisheries for swordfish and tunas and as a directed catch in coastal fisheries.  In coastal waters, artisanal fisheries use many types of shallow water gear to target sailfish (NMFS, 2003).

*Stock Status and Outlook*

Sailfish and longbill spearfish landings have historically been reported together in annual ICCAT landing statistics.  An assessment was conducted in 2001 for the western Atlantic sailfish stock based on sailfish/spearfish composite catches and sailfish "only" catches.  The assessment tried to address shortcomings of previous assessments by improving abundance indices and separating the catch of sailfish from that of spearfish in the offshore longline fleets.  The 2001 assessment looked at catches reported between 1956 and 2000 and all the quantitative assessment models used produced unsatisfactory fits, therefore the SCRS recommended applying population models that better accounted for these dynamics in order to provide improved assessment advice.  For the western Atlantic stock, annual sailfish catches have averaged about 700 mt (1,543,235 lb) over the past two decades and the abundance indices have remained relatively stable.  The 2000 yield was 506 mt (1,115,539 lb) (Table 3.15).  The reported catches of sailfish/spearfish (Task I) for 2004 were 1,017 and 1,088 mt for the west and east Atlantic, respectively.  Recent analyses did not provide any information on the MSY or other stock benchmarks for the 'sailfish only' stock.  In the eastern Atlantic, abundance indices based on coastal/inshore fisheries for sailfish have decreased in recent years, while those attained from the Japanese longline fishery indicate constant estimates of abundance since the mid-1970s (SCRS, 2004).

Based on the 2001 assessment, it is unknown if the western or eastern sailfish stocks are undergoing overfishing or if the stocks are currently overfished.  Therefore, SCRS recommended that Contracting Parties consider methods to reduce fishing mortality rates, overall, and that western Atlantic catches should not be increased above current levels.  Furthermore, the SCRS expressed concern about the incomplete reporting of catches, particularly in recent years.

A summary of Atlantic sailfish stock assessment data is given in Table 3.15.  The evolution of estimated sailfish/spearfish catches in the Atlantic during the period 1956 – 2002 for both east and west stocks is given in Figure 3.19.  Available CPUE for western Atlantic sailfish/spearfish for the period 1967 – 2000 is shown in Figure 3.20.  Estimated sailfish only catches from 1956 – 2000 are shown in Figure 3.21.

*Effect of Regulations*

ICCAT Management Recommendations

No ICCAT management regulations are currently in effect for Atlantic sailfish. Sailfish are managed as distinct eastern and western Atlantic stocks. This separation into two management units is based on life history information. General management recommendations made by the SCRS to ICCAT have remained consistent in recent years. These management recommendations indicated that ICCAT should consider methods for reducing fishing mortality rates. The current western Atlantic assessment led the SCRS to recommend that the West Atlantic sailfish "only" catches should not exceed current levels. For the East Atlantic, the SCRS recommended that sailfish "only" catches should not exceed current levels and that ICCAT should consider practical and alternative methods to reduce fishing mortality and assure data collection systems. SCRS expressed concern about the incomplete reporting of catches, particularly for the most recent years, the lack of sufficient reports by species, and evaluations of the new methods used to split the sailfish and spearfish catch and to index abundance. The SCRS recommended all countries landing sailfish/spearfish or having dead discards, report these data to the ICCAT Secretariat and that the SCRS should consider the possibility of a spearfish "only" assessment in the future (SCRS, 2004).

Domestic Regulations

Please see the discussion of domestic regulations contained in section 3.2.4.1, above.

*Recent and Ongoing Research*

Please see the discussion of recent and ongoing research contained in section 3.2.4.1, above.

#### 3.2.4.4 Longbill Spearfish

The longbill spearfish (*Tetrapturus pfluegeri*) are the most rare of the Atlantic istiophorids, and were identified as a distinct species in 1963. There is relatively little information available on spearfish life history. A related istiophorid, the Mediterranean spearfish (*Tetrapturus belone*), is the most common representative of this family in the Mediterranean Sea. Longbill spearfish are known to occur in epipelagic waters above the thermocline, off the east-coast of Florida, the Bahamas, the Gulf of Mexico, and from Georges Bank to Puerto Rico. Junior et al. (2004) captured spearfish off the coast of Brazil at depths ranging from 50 – 190 m (164 – 623 feet). The geographic range for this species is from 40°N to 35°S.

Spearfish spawn from November to May and females are generally 17 – 19 kg (37.4 – 41.8 lb) and 160 – 170 cm (63 – 66 inches) at first maturity. These fish are unique among istiophorids in that they are winter spawners. Larval spearfish have been identified from the vicinity of the Mid-Atlantic ridge from December to February, indicating that this species spawns in offshore waters (de Sylva and Breder, 1997).

Common prey items include fish and squid. Specifically, Junior et al. (2004) observed 37 stomachs and found that oceanic pomfret and squid comprised 63 percent of the items identified in stomachs. Most prey items were between 1 – 10 cm (0.39 – 3.9 inches) in length, with a mean length of 6.7 cm (2.63 inches). The maximum number of prey items found in any individual stomach was 33.

Similar to sailfish, spearfish are caught incidentally or as bycatch in offshore longline fisheries by many nations. There are also artisinal fisheries that take place in the Caribbean Sea and in the Gulf of Guinea. Directed recreational fisheries for spearfish are limited due to the fact that the fish are generally located further offshore than other istiophorids. The reported catches of sailfish/spearfish (Task I) for 2003 are 1,310 and 416 mt (2,888,055 and 917,123 lb) for the west and east Atlantic, respectively. The 2001 – 2003 reported catch of unclassified billfish was 12 percent of the reported catch for all billfish and, for some fisheries, this proportion is much greater. This is a problem for species like spearfish for which there is already a paucity of data (SCRS, 2004).

*Stock Status and Outlook*

Initial stock assessments conducted on spearfish aggregated these landings with sailfish. As mentioned in the Sailfish section, the 2001 assessment included a ‘sailfish only’ in addition to an aggregate sailfish/spearfish assessment. West Atlantic catch levels for sailfish/spearfish combined seem sustainable because, over the past two decades, CPUE and catch levels have remained constant, however, MSY is unknown. As a result, it is unknown whether or not spearfish are experiencing overfishing or are overfished. Spearfish catch levels are shown in Figure 3.24. The SCRS recommends implementing measures to reduce or keep fishing mortality levels constant and evaluating new methods to split sailfish and spearfish indices of abundance (SCRS, 2004).

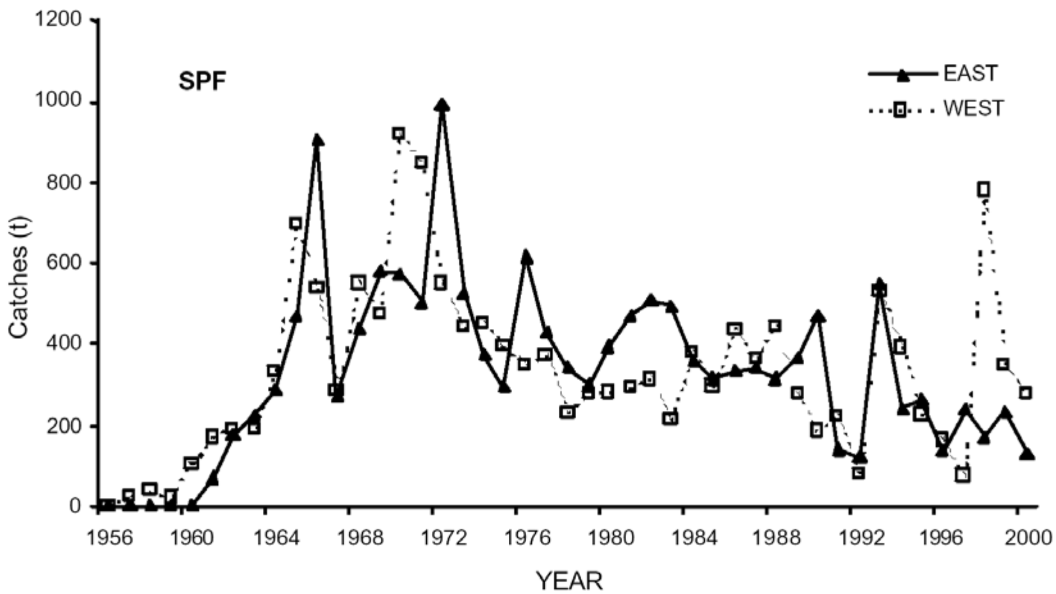

**Figure 3.24 Estimated spearfish "only" catches in the Atlantic based on the new procedure for splitting combined sailfish and spearfish catches from 1956-2000. Weights are in metric tons, whole weight.** Source: SCRS, 2005.

*Effect of Regulations*

ICCAT Management Recommendations

No ICCAT management regulations are currently in effect for Atlantic longbill spearfish. Management recommendations are similar to those listed for sailfish, including: consider methods for Contracting Parties to reduce mortality rates, encourage Contracting Parties to provide complete reporting of spearfish catches, evaluate new methods to split the sailfish and spearfish catch/index abundance, and assess sailfish independently of spearfish.

Domestic Regulations

Please see the discussion of domestic regulations contained in section 3.2.4.1, above.

*Recent and Ongoing Research*

Please see the discussion of recent and ongoing research contained in section 3.2.4.1, above.

### 3.2.5 Atlantic Sharks

#### 3.2.5.1 Life History/Species Biology

Sharks belong to the class Chondrichthyes (cartilaginous fishes) that also includes rays, skates, and deepwater chimaeras (ratfishes). From an evolutionary perspective, sharks are an old group of fishes characterized by skeletons lacking true bones. The earliest known sharks have been identified from fossils from the Devonian period, over 400 million years ago. These primitive sharks were small creatures, about 60 to 100 cm long, that were preyed upon by larger armored fishes that dominated the seas. The life span of all shark species in the wild is not known, but it is believed that many species may live 30 to 40 years or longer.

Relative to other marine fish, sharks have a very low reproductive potential. Several important commercial species, including large coastal carcharhinids, such as sandbar (*Carcharhinus plumbeus)* (Casey and Hoey, 1985; Sminkey and Musick, 1995; Heist *et al*., 1995), lemon (*Negaprion brevirostris)* (Brown and Gruber, 1988), and bull sharks (Branstetter and Stiles, 1987), do not reach maturity until 12 to 18 years of age. Various factors determine this low reproductive rate: slow growth, late sexual maturity, one to two-year reproductive cycles, a small number of young per brood, and specific requirements for nursery areas. These biological factors leave many species of sharks vulnerable to overfishing.

There is extreme diversity among the approximately 350 species of sharks, ranging from tiny pygmy sharks of only 20 cm (7.8 in) in length to the giant whale sharks, over 12 meters (39 feet) in length. There are fast-moving, streamlined species such as mako (*Isurus* spp.*)* and thresher sharks (*Alopias* spp.), and sharks with flattened, ray-like bodies, such as angel sharks (*Squatina dumerili)*. The most commonly known sharks are large apex predators including the white (*Carcharadon carcharias*), mako, tiger (*Galeocerdo cuvier*), bull (*Carcharhinus leucas)*, and great hammerhead (*Sphyrna mokarran*). Some shark species reproduce by laying eggs, others nourish their embryos through a placenta. Despite their diversity in size, feeding habits, behavior and reproduction, many of these adaptations have contributed greatly to the evolutionary success of sharks.

The most significant reproductive adaptations of sharks are internal fertilization and the production of fully developed young or "pups." These pups are large at birth, effectively reducing the number of potential predators and enhancing their chances of survival. During mating, the male shark inseminates the female with copulatory organs, known as claspers that develop on the pelvic fins. In most species, the embryos spend their entire developmental period protected within their mother's body, although some species lay eggs. The number of young produced by most shark species in each litter is small, usually ranging from two to 25, although large females of some species can produce litters of 100 or more pups. The production of fully-developed pups requires great amounts of nutrients to nourish the developing embryo.

Traditionally, these adaptations have been grouped into three modes of reproduction: oviparity (eggs hatch outside body), ovoviviparity (eggs hatch inside body), and viviparity (live birth).

Adults usually congregate in specific areas to mate and females travel to specific nursery areas to pup. These nurseries are discrete geographic areas, usually in waters shallower than those inhabited by the adults. Frequently, the nursery areas are in highly productive coastal or estuarine waters where abundant small fishes and crustaceans provide food for the growing pups. These areas also may have fewer large predators, thus enhancing the chances of survival of the young sharks. In temperate zones, the young leave the nursery with the onset of winter; in tropical areas, young sharks may stay in the nursery area for a few years.

Shark habitat can be described in four broad categories: (1) coastal, (2) pelagic, (3) coastal-pelagic, and (4) deep-dwelling. Coastal species inhabit estuaries, the nearshore and waters of the continental shelves, *e.g.*, blacktip (*Carcharhinus limbatus*), finetooth, bull, lemon, and sharpnose sharks (*Rhizoprionondon terraenovae*). Pelagic species, on the other hand, range widely in the upper zones of the oceans, often traveling over entire ocean basins. Examples include shortfin mako (*Isurus oxyrinchus*), blue (*Prionace glauca*), and oceanic whitetip (*Carcharhinus longimanus*) sharks. Coastal-pelagic species are intermediate in that they occur both inshore and beyond the continental shelves, but have not demonstrated mid-ocean or transoceanic movements. Sandbar sharks are examples of a coastal-pelagic species. Deep-dwelling species, *e.g.*, most cat sharks (*Apristurus* spp.) and gulper sharks (*Centrophorus* spp.) inhabit the dark, cold waters of the continental slopes and deeper waters of the ocean basins.

Seventy-three species of sharks are known to inhabit the waters along the U.S. Atlantic coast, including the Gulf of Mexico and the waters around Puerto Rico and the U.S. Virgin Islands. Thirty-nine species are managed by HMS; spiny dogfish also occur along the U.S. coast, however management for this species is under the authority of the Atlantic States Marine Fisheries Commission as well as the New England and Mid-Atlantic Fishery Management Councils. Deep-water sharks were removed from the management unit in 2003. Based on the ecology and fishery dynamics, the sharks have been divided into four species groups for management: (1) large coastal sharks, (2) small coastal sharks, (3) pelagic sharks, and (4) prohibited species (Table 3.16).

**Table 3.16 Common names of shark species included within the four species management units under the purview of the HMS management division.**

| | Shark Species Included |
|---|---|
| Large Coastal Sharks (11) | Sandbar, silky, tiger, blacktip, bull, spinner, lemon, nurse, smooth hammerhead, scalloped hammerhead, and great hammerhead sharks |
| Small Coastal Sharks (4) | Atlantic sharpnose, blacknose, finetooth, and bonnethead sharks |
| Pelagic Sharks (5) | Shortfin mako, thresher, oceanic whitetip, porbeagle, and blue sharks |
| Prohibited Species (19) | Whale, basking, sandtiger, bigeye sandtiger, white, dusky, night, bignose, Galapagos, Caribbean reef, narrowtooth, longfin mako, bigeye thresher, sevengill, sixgill, bigeye sixgill, Caribbean sharpnose, smalltail, and Atlantic angel sharks |

### 3.2.5.2 Stock Status and Outlook

NMFS is responsible for conducting stock assessments for the Large and Small Coastal Shark complexes (LCS and SCS) (Cortes, 2002; Cortes *et al*., 2002). ICCAT and the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) have recently conducted assessments of three pelagic shark species. Stock assessments were conducted for the LCS and SCS in 2002. NMFS is conducting stock assessments for LCS and SCS in 2006 and 2007, respectively. NMFS also recently released a stock assessment for dusky sharks (May 25, 2006, 71 FR 30123). Species-specific assessments for blacktip and sandbar sharks within the LCS complex and finetooth sharks, Atlantic sharpnose sharks, blacknose sharks (*Carcharhinus acronotus*), and bonnethead sharks (*Sphyrna tiburo*) within the SCS complex, were also conducted in 2002. The conclusions of these assessments are summarized in Table 3.18 and Table 3.17 and are fully described in Amendment 1 to the 1999 Atlantic Tunas, Swordfish, and Sharks FMP. Summaries of recent stock assessments and reports on several species of pelagic sharks (blue sharks, shortfin mako sharks, and porbeagle sharks (*Lamna nasus*) by Committee on the Status of Endangered Wildlife in Canada (COSEWIC) and ICCAT are also included in this section. More detailed information on life history and distribution of sharks can be found in Appendix B (EFH).

### 3.2.5.3 Large Coastal Sharks

The last LCS stock assessment was held in June 2002, however, results from a new stock assessment should be released in 2006. Discussions of the 2002 stock assessment focused on the availability of four additional years worth of catch estimates, biological data, catch rate series, and the types of models that should be used. The modeling itself was performed after the Shark Evaluation Workshop and incorporated new catch and effort estimates for the years 1998 – 2001 as well as over 20 catch-per-unit-effort (CPUE) series for the LCS complex, sandbar, and blacktip sharks (

Table 3.17).

A variety of stock assessment models were used to investigate the population dynamics of LCS including: (1) a non-equilibrium Schaefer biomass dynamic model using the sampling/importance re-sampling (SIR) algorithm (Bayesian SPM) and several weighting schemes; (2) a non-equilibrium Schaefer state-space surplus production model (SSSPM) using a Markov Chain Monte Carlo (MCMC) method for numerical integration; (3) a lagged recruitment, survival, and growth (SSLRSG) state-space model; (4) the maximum likelihood estimation model (MLE); and (5) a fully age-structured, state-space population dynamic model (ASPM). General descriptions of these models can be found in the stock assessment. The use of multiple approaches in evaluating stock status can reduce uncertainty in the best available data and can balance individual model strengths and weaknesses.

Due to concerns that catch series may underestimate mortality from the commercial fishery, four separate catch scenarios were considered to evaluate catch histories: updated, baseline, and the alternative scenarios. The updated catch scenario was comprised of catches used in the 1998 SEW, including data through 1997, and additional catches for 1998 – 2001. The baseline catch scenario included similar information and discards from the menhaden fishery, and Mexican catches, bottom longline discards back to 1981, and commercial and recreational catches back to 1981. The alternative scenario reconstructed historical catches back in time (calendar years 1960 – 2001) and applied to the LCS complex only. The age-structured models for sandbar and blacktip shark included both updated and baseline scenarios in which specific catch series were linked to specific catchability and selectivity parameters. The alternative scenarios were used for sandbar and blacktip shark catch history evaluation.

Catch rates were also analyzed for other species included in the LCS complex such as tiger, hammerhead, dusky, and silky shark. Generally, commercial data indicate increasing catch rates for tiger shark (Brown and Cramer, 2002; Cortes *et al.*, 2002) as well as decreasing trends for dusky shark, sand tiger shark, and hammerhead shark (Brown, 2002; Cortes *et al.*, 2002; Brown and Cramer, 2002). Recreational catch data for hammerhead and bull shark point towards declining trends for both species (Cortes *et al.*, 2002).

Considering the outputs of all model analyses combined, the assessment results were considerably more pessimistic for the LCS aggregate as compared to those for individual species within the complex (*i.e.*, sandbar and blacktip sharks). While results illustrate improvements in the LCS complex since 1998, all of the models and catch scenarios described above, with the exception of the Bayesian SPM scenario which used only fishery-independent CPUE series, indicate that overfishing may be occurring and that the LCS complex may be overfished. Tables 3.4 and 3.5 provide biomass and fishing mortality estimates used to make these determinations. As such, the stock assessment finds that at least a 50-percent reduction in 2000 catch levels for the complex could be required for the biomass to reach maximum sustainable yield (MSY) in 10, 20 or 30 years. Furthermore, a 20-percent reduction in 2000 catch levels for the complex would result in less than a 50-percent probability of achieving MSY even after 30 years of implementation under those catch levels. Overall, the stock assessment found that the LCS complex as a whole is overfished and overfishing is occurring (Cortes *et al.*, 2002).

The assessment acknowledges that the results between the complex and sandbar and blacktip sharks may be considered conflicting, given that sandbar and blacktip sharks comprise the majority of LCS commercial harvests. Specifically, sandbar and blacktip sharks make up approximately 44 percent of the total commercial catch (Burgess and Morgan, 2003) and over 70 percent of the landings (Cortes and Neer, 2002). The remainder of the catch is comprised mostly of tiger, scalloped hammerhead, silky, and sand tiger, with catch composition varying by region (Burgess and Morgan, 2003). These species are less marketable and are often released, so they are reflected in the overall catch but not the landings. Nonetheless, the complex represents a variety of species beyond sandbar and blacktip shark, some of which are in apparent decline.

In December 2002, the peer review process of the 2002 LCS stock assessment was completed as required by a court settlement agreement. The peer reviews were conducted by three separate non-NMFS reviewers who were asked to respond to five questions regarding the appropriateness of specific modeling approaches and the selection there of, consideration of available data and the quality of data sets, application of available data in selected models, reliability of projections, and the effects of various catch scenarios on stock trajectories. Peer review findings were generally positive in that reviewers agreed that a state-of-the-art assessment was performed and that the best available science was employed. Reviewers noted assessment strengths including (1) compilation of several indices of abundance, (2) consideration of multiple stock assessment models, including Bayesian analyses, (3) discussion of myriad alternative harvest policies, and (4) analytical changes to address concerns raised by previous reviewers. Further investigation of catch series indices, assessment of individual species within the LCS complex, investigation of age and age-sex-area assessment models, consideration of alternative harvest policies in contrast to the current constant-catch policy, and NMFS support for observer programs to obtain fishery independent estimates of abundance were among the recommendations offered for improvements to future stock assessment for LCS.

The 2005/2006 stock assessment for LCS follows the Southeast Data, Assessment, and Review (SEDAR) process. This process is a cooperative program designed to improve the quality and reliability of the stock assessments. The SEDAR process emphasizes constituent and stakeholder participation in the assessment development, transparency in the assessment process, and a rigorous and independent scientific review of the completed stock assessment. The Data Workshop for the stock assessment, which documented, analyzed, reviewed, and compiled the data for conducting the assessment, was held from October 31 to November 4, 2005, in Panama City, FL (September 15, 2005, 70 FR 54537; correction October 5, 2005, 70 FR 58190). The Assessment Workshop, which developed and refined the population analyses and parameter estimates, was held from February 6 to February 10, 2006, in Miami, FL (December 22, 2005, 70 FR 76031). At the time of writing this Final HMS FMP, the last workshop, the Review Workshop, had not yet occurred. At the Review Workshop, independent scientists should review the assessment and data. This Workshop should be held on June 5 to June 9, 2006, in Panama City, FL (March 9, 2006, 71 FR 12185). The final results should be released after the review workshop. All reports are posted on SEDAR webpage when complete (http://www.sefsc.noaa.gov/sedar/).

Recently, the SEFSC released the first dusky shark stock assessment (May 25, 2006, 71 FR 30123). Results from all of the models used were similar with all models indicating that the stock is heavily exploited. The stock assessment summarizes relevant biological data, discusses the fisheries affecting the species, and details the data and methods used to assess the stock. At the time of writing this Final HMS FMP, NMFS is reviewing the stock assessment and considering implications for management.

#### 3.2.5.4 Small Coastal Sharks

A stock assessment for small coastal sharks (SCS) was also conducted in 2002. This was the first assessment since 1992 and as such the assessment included new information regarding SCS age and growth, reproduction, and population dynamics. Additional information relative to commercial and recreational catches as well as extended bycatch estimates for the shrimp trawl fishery were also considered.

Trends in catch were analyzed for the SCS complex as well as the four species comprising this aggregate grouping (Table 3.18). Overall, SCS commercial landings exceeded recreational harvest in all years since 1996, with the exception of 2000. Of the four species of SCS analyzed, bonnetheads contributed to over 50 percent of all SCS commercial landings in 1995, but Atlantic sharpnose and finetooth sharks each accounted for over 30 percent of the commercial landings in years 1996 – 1999 and 1998 – 2000 respectively. Atlantic sharpnose dominated recreational catch in all years between 1995 and 2000.

Also, in 2002, researchers at the Mote Marine Laboratory and the University of Florida, conducted a stock assessment for SCS using similar data but different models. The results were similar to the NMFS assessment in that current biomass levels for Atlantic sharpnose, bonnethead, and blacknose were at least 69 percent of the biomass in 1972 while the current biomass level for finetooth sharks was only nine percent the level in 1972 (Simpfendorfer and Burgess, 2002). Both stock assessments note that the data used for finetooth sharks is not as high a quality as the data used for Atlantic sharpnose due to shorter catch-per-unit-effort (CPUE) and catch series, lack of bycatch estimates, and no catches reported in some years.

NMFS intends to conduct a new stock assessment for SCS starting in 2007. The new stock assessment would follow the SEDAR process.

*Finetooth Sharks*

Additional information on finetooth sharks and the results specific to this species from the 2002 SCS stock assessment are provided in this section because finetooth sharks were the only exception to the results of the assessment, in that fishing mortality in the final five years of data considered was above the mortality level associated with producing MSY. As such, finetooth sharks are not overfished, however, overfishing is occurring (Table 3.17 and Table 3.20). Sections 2.2.2 and 4.2.2 provide more detail on the alternatives that were considered to prevent overfishing of finetooth sharks.

Finetooth sharks inhabit shallow coastal waters to depths of 10 m (32.8 feet) near river mouths in the Gulf of Mexico and South Atlantic Ocean between Texas and North Carolina. These fish often form large schools and migrate to warmer waters when water temperatures drop below 20°C (68°F). Finetooth sharks are relatively productive compared to other sharks as fish are sexually mature at 3.9 (TL = 118 cm (46 inches)) and 4.3 (TL = 123 cm (48 inches)) years for males and females, respectively (Carlson *et al*., 2003). Reproduction in finetooth sharks is viviparous with yolk sac placenta and embryos nourished through a placental connection. Females move into the nursery areas in late May and gestation is approximately 12 months. Each litter can have 1 – 6 pups with individuals measuring 51 – 64 cm (20 – 25 inches) in length. The finetooth shark feeds primarily on mullet, Spanish mackerel, spot, Atlantic menhaden, cephalopods, and crustacean (Bester and Burgess, 2004).

In 2002, NMFS conducted a stock assessment for all SCS, including finetooth sharks. Five catch rate series were used, including fishery-independent and -dependent data. The fishery-independent data sources included the NMFS Pascagoula and Panama City Laboratory longline surveys (NMFS SE LL and NMFS LL PC), and the NMFS Panama City Laboratory Gillnet Survey (NMFS GN). Fishery-dependent catch series data were included from the combined recreational series and the Directed Shark Gillnet Fishery Observer Program (DSGFOP). This catch rate series data were combined with life history information for finetooth sharks and evaluated with several stock assessment models. There were four models utilized for the assessment and numerous scenarios within each model, producing a range of point estimates for fishing mortality, relative fishing mortality, biomass, relative stock biomass, maximum fishing mortality threshold, minimum stock size threshold, and other parameters.

Of the catch series data used in the analysis, three of the five showed a positive trend (*i.e.*, had positive slopes) in catch over time, suggesting an increase in finetooth shark abundance. The catch series data showing positive trends were DSGFOP (0.03), NMFS SE LL (0.34), and NMFS LL PC (0.04); however only the slope for the DSGFOP catch series data was statistically significant different from zero (*P* = 0.03). However, it should be noted that data were missing from some years in the NMFS SE LL and the DSGFOP catch series data; therefore, one cannot necessarily assume that finetooth sharks are increasing in abundance. The other two datasets, NMFS LL PC and NMFS GN PC, had negative trends in catch over time as indicated by their negative slopes (-0.24 and -0.11, respectively) but neither trend was statistically significant from zero. Overall, the slopes for the small coastal shark (SCS) complex as a whole and other individual species were relatively flat, indicating that the relative abundance of the stocks remained fairly stable during the exploitation phase (Cortés, 2002).

Four different stock assessment models were used to evaluate the status of SCS using Bayesian statistical techniques. Results of both surplus production models and the Lagged Recruitment Survival and Growth State Space model (LRSG) (using several different scenarios) indicate that the current level of removals is sustainable for the SCS aggregate and the individual species within the complex. Relative stock biomass and fishing mortality trajectories obtained with the Bayesian state-space Schaefer surplus production model (SPM) for the small coastal aggregate and the Atlantic sharpnose sharks followed similar trends, since the catches were dominated by these species. The model predicted that the stock biomass for the small coastal shark complex in any given year from 1972 – 2000 exceeded the biomass producing MSY. Relative fishing mortality ($F/F_{MSY}$) was generally below one for the SCS complex, but for finetooth sharks, the final five values of F in the series (1996 – 2002) estimated by the model were above the level of F corresponding to MSY.

Results for finetooth sharks were directly influenced by the catch series used, which did not include any bycatch estimates, and this, in turn, influenced certain parameters of the Bayesian models (specifically, the priors chosen for K, which describes uncertainty in assessment models) (Cortés, 2002). The lack of bycatch data in the catch series data lead to low values of MSY predicted for finetooth sharks in the SCS stock assessment (especially those obtained through the SPM models). This lack of bycatch data and shorter catch and catch per unit effort (CPUE) series, coupled with no catches reported in some years, led to some uncertainty in the stock assessment for finetooth sharks. In the case of finetooth sharks, model estimates of recent F levels are above $F_{MSY}$, indicating that recent levels of effort directed at this species, if continued, could result in an overfished status in the relatively near future. The various stock assessments models used and sensitivity analyses run support these general conclusions (Cortés, 2002). Future work should continue to monitor the status of this individual species (Cortés, 2002).

Landings of finetooth sharks in other fisheries are extensive; however, catch series data from these fisheries are currently unavailable. The inclusion of such data in future stock assessments will provide better information on both fishing effort and estimates of MSY. Thus, it may be prudent to develop a plan to prevent overfishing that first investigates other sources of fishing mortality before initiating a particular set of management actions. In order to capture additional catch series data on fisheries contributing to finetooth fishing mortality, NMFS is expanding observer programs to include DSGFOP observers on all boats that have directed or incidental shark permits to determine if these gillnet vessels in the South Atlantic are contributing to the majority of fishing mortality. A continuation of a pilot program initiated in the spring of 2005 that placed observers on board additional gillnet vessels targeting other fish species will improve data collection efforts. Furthermore, contacting Regional Fishery Management Councils and Interstate Marine Fisheries Commissions to determine sources of mortality occurring under other fishery management plans, and having finetooth sharks included as a select species for sub-sampling of bycatch in the Gulf of Mexico Shrimp Trawl Observer Program will provide additional landings data necessary for appropriate management and conservation actions in the future.

### 3.2.5.5 Pelagic Sharks

Pelagic sharks are subject to exploitation by many different nations and exhibit trans-oceanic migration patterns. As a result, ICCAT's Standing Committee on Research and Statistics (SCRS) Subcommittee on Bycatch has recommended that ICCAT take the lead in conducting stock assessments for pelagic sharks.

An ICCAT meeting was held in September 2001 to review available statistics for Atlantic and Mediterranean pelagic sharks. Newly available biological and fishery information presented for review included age and growth, length/weight relationships, species identification, species composition of catch, catch per unit effort, mortality (both natural and fishing estimates for blue sharks), bycatch, and tagging and migration studies. Landings estimates, which incorporated data for both the Atlantic and Mediterranean populations of blue shark, suggested that landings declined in 2000 (3,652 mt) following a peak of 32,654 mt in 1999. Landings of porbeagles peaked in 1997, with an estimated total of 1,450 mt, and have slowly declined each year since that time period (1998 – 2000). Similarly, landing estimates for Shortfin mako also peaked in 1997 (5,057 mt) and have declined by 83 percent (863 mt in 2000) since that time. Meeting participants expressed concern regarding the lack of information pertaining to the number of fleets catching sharks, landing statistics, and dead discards for sharks.

The SCRS decided to conduct an assessment of Atlantic pelagic sharks beginning in 2004. Emphasis was placed on blue sharks and shortfin mako sharks. Several models such as non-equilibrium production and statistical age/length-structured models will be considered to analyze the population dynamics of pelagic shark species.

*ICCAT Stock Assessment on Blue and Shortfin Mako Sharks*

At the 2004 Inter-Sessional Meeting of the ICCAT Subcommittee on bycatch, stock assessments for Atlantic blue shark (*Prionace glauca*) and shortfin mako (*Isurus oxyrinchus*) were conducted. This work included a review of their biology, a description of the fisheries, analyses of the state of the stocks and outlook, analyses of the effects of current regulations, and recommendations for statistics and research. The assessment indicated that the current biomass of North and South Atlantic blue shark seems to be above MSY ($B>B_{MSY}$), however, these results are conditional and based on assumptions that were made by the committee. These assumptions indicate that blue sharks are not currently overfished, again, this conclusion is conditional and based on limited landings data. The committee estimates that between 82,000 and 114,000 mt ww (180,779,054 – 251,326,978 lb) of blue shark are harvested from the Atlantic Ocean each year.

The North Atlantic shortfin mako population has experienced some level of stock depletion as suggested by the historical CPUE trend and model outputs. The current stock may be below MSY ($B<B_{MSY}$), suggesting that the species may be overfished. Overfishing may also be occurring as between 13,000 and 18,000 mt ww (28,660,094 – 39,683,207 lb) of shortfin mako are harvested in the Atlantic Ocean annually. South Atlantic stocks of shortfin mako shark are likely fully exploited as well, but depletion rates are less severe than in the North Atlantic.

The results of both of these assessments should be considered preliminary in nature due to limitations on quality and quantity of catch data available (SCRS, 2004). The subcommittee stated that catch data currently being reported to ICCAT does not represent the total catch actually landed, and are very limited with regard to size, age, and sex of shark harvested or caught incidentally. In order to attain a more accurate estimate of total landings, and improve future stock assessments, the committee made several recommendations, including: increase the infrastructure investment for monitoring the overall catch composition of sharks, standardize catch per unit effort (CPUE) from major fishing fleets, expand use of trade statitistics (fins) to extend historical time series, and include scientists from all Contracting Parties with significant blue and shortfin mako catches in future assessments (SCRS, 2004).

*COSEWIC Stock Assessment on Porbeagle*

The Committee on the Status of Endangered Wildlife in Canada (COSEWIC) conducted a species report and assessment for porbeagle in 2004. They suggest that significant declines in porbeagle abundance have occurred as a result of overexploitation in fisheries. In 2001, porbeagle biomass was estimated at 4,409 mt ww (9,720,181 lb), a decline of 89 percent from the pre-fishing biomass in 1961 (COSEWIC, 2004). The model employed predicts that populations declined precipitously after the fishery was developed in 1961, recovered slightly in the 1980s, and then declined again to the current level. Porbeagle quotas have been reduced significantly for Canadian fisheries. NMFS is interested in working with the Canadian government to address concerns raised by the COSEWIC report. Currently, NMFS has a species-specific quota of 92 mt dw (202,823 lb) for porbeagle. These fish are generally harvested incidentally in the pelagic longline fisheries. Between 2000 and 2003, landings of porbeagle were approximately 3.4 mt dw for the four fishing years, combined (0.85 mt dw/year). NMFS is currently reviewing the latest Canadian stock assessment in terms of the overfishing and overfished thresholds defined in the FMP. At this time, the status of porbeagle sharks is unknown; however, if the stock is found to meet the thresholds, the status would be redefined.

#### 3.2.5.6 Effects of Regulations

Atlantic sharks have been managed by NMFS since the 1993 FMP for Atlantic Sharks. The 1999 FMP for Atlantic Tunas, Swordfish, and Sharks addressed numerous shark management measures, including: reducing commercial LCS and SCS quotas; establishing a commercial quota for blue sharks and a species-specific quota for porbeagle sharks; expanding the list of prohibited shark species; implementing a limited access permitting system in commercial fisheries; and establishing season-specific over- and under-harvest adjustment procedures. The 1999 FMP also partitioned the LCS complex into ridgeback and non-ridgeback categories but did not include regional quota measures. Due to litigation, many management measures in the 1999 FMP were not implemented.

The final rule implementing Amendment 1 to the 1999 FMP was published in the Federal Register on December 23, 2003. This final rule revised the shark regulations based on the results of the 2002 stock assessments for SCS and LCS. Results of these stock assessments indicate the SCS complex is not overfished (e.g. depleted in abundance) and overfishing is not occurring; the LCS complex continues to be overfished, and overfishing is occurring; sandbar sharks are not overfished, but overfishing is occurring; blacktip shark stocks are rebuilt and healthy; and finetooth sharks are not overfished, but overfishing is occurring. In Amendment 1 to the 1999 FMP, NMFS revised the rebuilding timeframe for LCS to 26 years from 2004, and implemented several new regulatory changes. Management measures enacted in the amendment included: re-aggregating the large coastal shark complex; using maximum sustainable yield (MSY) as a basis for setting commercial quotas; eliminating the commercial minimum size restrictions; implementing a commercial trip limit for LCS and SCS; implementing trimester commercial fishing seasons effective January 1, 2005; imposing gear restrictions to reduce bycatch; implementing a time/area closure off the coast of North Carolina effective January 1, 2005; and establishing three regional commercial quotas (Gulf of Mexico, South Atlantic, and North Atlantic) for LCS and SCS management units. For more detail on the management history surrounding shark regulations see Section 3.1.

As a result of using the MSY as a basis for setting quotas and implementing a new rebuilding plan, the overall quota for LCS in 2004 of 1,017 metric tons (mt) dressed weight (dw) (2.24 million lbs dw) was lower than both the 2002 LCS quota of 1,285 mt dw (2.83 million lbs dw) and the 2003 LCS quota of 1,714 mt dw (3.78 million lbs dw). The annual SCS quota is 454 mt dw per year. The annual quotas for pelagic sharks are 273 mt dw for blue sharks, 92 mt dw for porbeagle sharks, and 488 mt dw for pelagic sharks other than porbeagle and blue sharks.

The regulations governing the recreational and commercial shark fisheries allow opportunities for participants to pursue sharks for leisure, subsistence, and/or commercial gain while maintaining compliance with statutes that include, but are not limited to, the Magnuson Stevens Act, Endangered Species Act, Marine Mammal Protection Act, and the National Environmental Policy Act. These regulations seek to minimize bycatch of non-target, prohibited shark species, and protected resources by a variety of measures, including, but not limited to: mandating the use of corrodible, non-stainless steel hooks; requiring possession of handling and release equipment for protected resources (long handled line cutters and dipnets); conducting gillnet checks every two hours; mandatory observer coverage for commercial fisheries (if selected); limits on the deployment and operation of authorized gears; and, maintaining 19 species of shark on the prohibited species list (possession not authorized). Rebuilding overfished stocks is another objective of shark fishery regulations, and is accomplished through numerous measures, including, but not limited to: regional and trimester fishing quotas based on MSY; regional and trimester fishing seasons; commercial trip limits (4,000 lbs dw for LCS); recreational bag limits (1 shark/vessel/day for all authorized species except Atlantic sharpnose and bonnethead sharks (1 shark/person/day); and, recreational minimum size limits (>54” FL for all authorized species except Atlantic sharpnose and bonnethead sharks). Controlling fishing effort is accomplished by the requirement to possess a limited access permits for commercial shark fisheries and upgrading restrictions for transferred permits. Reducing fishing mortality of prohibited dusky sharks and juvenile sandbar sharks is achieved by the Mid-Atlantic time area closure (January 1 – July 31) and the requirement to use VMS when bottom longline gear is onboard during this time period.

Shark landings are monitored for adherence to regional and trimester quotas by requiring the submission of shark dealer landings reports every two weeks. Fishermen must also submit trip reports describing target and incidental landings within seven days of offloading. These data are used for stock assessments. Regulations are subject to change based on stock assessments, international obligations, litigation, and public sentiment. An updated LCS stock assessment should be available in 2006 and data workshops for an updated SCS stock assessment are scheduled to begin in early 2007. Domestic management measures affecting the U.S. shark fishery are constantly being evaluated for their effectiveness; furthermore, the United States is taking steps to improve the conservation and management of pelagic sharks within international fora, including ICCAT.

At the 2004 ICCAT annual meeting in New Orleans, ICCAT adopted a recommendation concerning the conservation of sharks caught in association with fisheries managed by ICCAT. This was the first binding measure passed by ICCAT dealing specifically with sharks. This recommendation includes, among other measures: reporting of shark catch data by Contracting Parties, a ban on shark finning, a request for Contracting Parties to live-release sharks that are caught incidentally, a review of management alternatives from the 2004 assessment on blue and shortfin mako sharks, and a commitment to conduct another stock assessment of selected pelagic shark species no later than 2007. In 2005, additional measures pertaining to pelagic sharks were added to the 2004 ICCAT recommendation. Measures included a requirement for contracting parties that have not yet implemented the 2004 recommendation, to reduce shortfin mako mortality, and annually report on their efforts to the commission.

#### 3.2.5.7 Recent and Ongoing Research

*Northeast Fisheries Science Center*

Fishery Independent Survey for Coastal Sharks

The biannual fishery independent survey of Atlantic large and small coastal sharks in US waters from Florida to Delaware was conducted from April 19 to June 1, 2004. The goals of this survey are to: (1) monitor the species composition, distribution, and abundance of sharks in the coastal Atlantic; (2) tag sharks for migration and age validation studies; (3) collect biological samples for age and growth, feeding ecology, and reproductive studies; and (4) collect morphometric data for other studies. Results from this 2004 survey included 557 sharks representing eight species caught on 69 longline sets. The time series of abundance indices from this survey are critical to the evaluation of coastal Atlantic shark species.

Age and Growth of Coastal and Pelagic Sharks

A comprehensive aging and validation study for the shortfin mako (*Isurus oxyrinchus)*, continued in conjunction with scientists at Moss Landing Marine Laboratories, California using bomb carbon techniques. Additional validation studies have begun on the sandbar shark, (*Carcharhinus plumbeus),* dusky shark, (*Carcharhinus obscurus),* tiger shark, (*Galeocerdo cuvieri)*, and white shark, (*Carcharodon carcharias)*. Age and growth studies on the tiger shark (with scientists at the University of New Hampshire), thresher shark, (*Alopias vulpinus)* (with scientists at the University of Rhode Island), night shark, (*Carcharhinus signatus)* (with NMFS scientists at the SEFSC Panama City Laboratory), and the bull shark, (*Carcharhinus leucas)* (with scientists with the Florida Division of Natural Resources) are underway. Collection, processing, photographing, and reading of samples are in various stages for these species including intercalibration of techniques, criteria, and band readings. This intercalibration process involves sharing samples and comparing counts between researchers including a researcher from the Natal Sharks Board, South Africa for joint work on shortfin mako, blue, and basking shark band periodicity. Collections of vertebra took place at tournaments and on the biannual research cruise with 285 sharks injected with OTC for validation. Night and dusky sharks were prepared with gross sectioning to determine the best method for reading and all processing was initiated using histology. Readings were completed on the thresher and tiger sharks towards intercalibration to generate bias graphs. Vertebrae, length-frequency data, and tag/recapture data collected from 1962 to present are being analyzed on each of these species to obtain growth parameters.

Biology of the Thresher Shark

Life history studies of the thresher shark continued. Data collection was augmented to include reproductive and food habits, in addition to age and growth information.

Biology of the Porbeagle Shark

A cooperative U.S./Canada research program continued on the life history of the porbeagle shark, (*Lamna nasus)* with preliminary analysis of porbeagle tagging and recaptures data using information from U.S., Canadian, and Norwegian sources.

Collection of Recreational Shark Fishing Data and Samples

Biological samples for age and growth, feeding ecology, and reproductive studies and catch data for pelagic sharks were collected at recreational fishing tournaments in the Northeast. Analysis of these tournament landings data was initiated by creating a database of historic information (1961 – 2004) and producing preliminary summaries of one long term tournament. The collection and analysis of these data are critical for input into species and age specific population and demographic models for shark management.

Cooperative Shark Tagging Program (CSTP)

The Cooperative Shark Tagging Program, operated by the Northeast Fisheries Science Center, has involved over 6,500 volunteer recreational and commercial fishermen, scientists, and fisheries observers conducted since 1962, continued to tag large coastal and pelagic sharks and provide information to define essential fish habitat for shark species in U.S. Atlantic and Gulf of Mexico waters. Since its inception, the CSTP has tagged over 128,000 sharks representing 40 species.

Atlantic Blue Shark Life History and Assessment Studies

A collaborative program to examine the biology and population dynamics of the blue shark, *Prionace glauca,* in the North Atlantic is ongoing. Research on the food and feeding ecology of the blue shark is being conducted cooperatively with University of Rhode Island staff with additional samples collected and a manuscript under revision. A detailed reexamination of the reproductive parameters of the blue shark continued with collection of additional biological samples to determine if any changes have occurred since the 1970s. A manuscript on blue shark stock structure based on tagging data was completed detailing size composition and movements between Atlantic regions. Additionally, a research focus on the population dynamics in the North Atlantic with the objectives of constructing a time series of blue shark catch rates (CPUE) from research surveys, estimation of blue shark migration and survival rates, and the development of an integrated tagging and population dynamics model for the North Atlantic for use in stock assessment continued in collaboration between NEFSC scientists and scientists at the School of Aquatic and Fishery Sciences, University of Washington. Progress to date includes the preliminary recovery of historical research survey catch data, size composition, and biological sampling data on pelagic sharks and preliminary analysis of survival and movement rates for blue sharks based on tag and release data from the NMFS CSTP. Preparation of standardized catch rate and size composition data compatible with pelagic longline observer data continued with a resulting ICCAT submission. As part of this comprehensive program, cooperative research continued with the Irish Marine Institute and Central Fisheries Board on mark-recapture databases including coordination of formats and programs with the NMFS CSTP for joint data analyses.

<u>Atlantic Shortfin Mako Life History and Assessment Studies</u>

A collaborative program with students and scientists at the University of Rhode Island to examine the biology and population dynamics of the shortfin mako in the North Atlantic was continued. Ongoing research included an update on age and growth and reproductive parameters and an examination of the predator-prey relationships between the shortfin mako and its primary prey, bluefish (*Pomatomus saltatrix)*. A manuscript was completed comparing contemporary and historic levels of bluefish predation. Future research includes the estimation of shortfin mako migration rates and patterns and survival rates using CSTP mark/recapture data and satellite tags with movements correlated with Advanced Very High Resolution Radiometer (AVHRR) sea surface temperature data. Toward these goals, two shortfin mako sharks were tagged with pop-up archival transmitting tags.

<u>Blacktip Shark Migrations</u>

Analysis of movements of the blacktip shark (*Carcharhinus limbatus)* in the western North Atlantic and Gulf of Mexico based on release and recapture data is ongoing with the examination of general migration patterns and exchange between and within regions of U.S. and Mexican waters. Release and recapture data were analyzed for evidence of Atlantic and Gulf primary and secondary blacktip nursery grounds.

<u>Cooperative Atlantic States Shark Pupping and Nursery Survey (COASTSPAN)</u>

NEFSC Apex Predators Program staff manages and coordinates this project that uses researchers in major coastal Atlantic states from Florida to Delaware to conduct a cooperative, comprehensive, and standardized investigation of valuable shark nursery areas. This research identifies which shark species utilize coastal zones as pupping and nursery grounds, gauges the relative importance of these areas, and determines migration and distribution patterns of neonate and juvenile sharks. This program is described in further detail in Section 3.3 of this document.

Juvenile Shark Survey for Monitoring and Assessing Delaware Bay Sandbar Sharks

NEFSC staff conduct this part of the COASTSPAN monitoring and assessment project for the juvenile sandbar shark population in the Delaware Bay nursery grounds using monthly longline surveys from June to September each year. A random stratified sampling plan based on depth and geographic location is ongoing to assess and monitor the juvenile sandbar shark population during the nursery season. In addition, the tagging and recapture data from this project are being used to examine the temporal and spatial relative abundance and distribution of sandbar sharks in Delaware Bay.

Habitat Utilization, Food Habits, and Essential Fish Habitat of Delaware Bay Sandbar and Smooth Dogfish Sharks

The food habits portion of the study characterizes the diet, feeding periodicity, and foraging habits of the sandbar shark as well as examines the overlap in diet and distribution with the smooth dogfish shark (*Mustelus canis)*. Stomach contents from over 800 sandbar sharks and over 200 smooth dogfish sharks have been sampled through a non-lethal lavage method. Acquired data will be coupled with environmental data, providing information on preferred habitat. This information is an important contribution towards understanding essential fish habitat and provides information necessary for nursery ground management and rebuilding of depleted shark populations.

Ecosystems Modeling

Ecosystem modeling, focusing on the role of sharks as top predators, will be conducted using ECOPATH - ECOSIM models, using the sandbar shark as a model species and examining the ecological interactions between sandbar and smooth dogfish sharks in Delaware Bay.

Overview of Gulf and Atlantic Shark Nurseries

Due to the requirement for a better understanding of shark nursery habitat in U.S. coastal waters, NEFSC staff serves as editors for an American Fisheries Society symposium proceedings volume on U.S. Atlantic and Gulf of Mexico coastal shark nursery ground and habitat studies.

Post-Release Recovery and Survivorship Studies in Sharks – Physiological Effects of Capture Stress

This ongoing research is directed towards the sandbar shark (*Carcharhinus plumbeus)*, and is being conducted cooperatively with Massachusetts Division of Marine Fisheries biologists. The study utilizes blood and muscle sampling methods in addition to acoustic tracking to obtain physiological profiles of individual sharks to characterize stamina and to determine ultimate post release survival. These analyses are requisite in view of the extensive current and proposed catch-and-release management strategies for coastal and pelagic shark species.

*Southeast Fisheries Science Center*

Stock Assessments of Pelagic, Large Coastal, and Prohibited Sharks

The ICCAT Subcommittee on Bycatch conducted a stock assessment of blue sharks and shortfin makos in Tokyo, Japan, in June 2004. All information available on biology, fisheries, stock identity, catch, CPUE, and size of these species was reviewed and an evaluation of the status of stocks conducted using surplus production, age-structured, and catch-free stock assessment models. U.S. scientists contributed eight working documents for this meeting on various aspects of shark biology and methods to assess stock status; SEFSC scientists participated in the assessment process and authored or co-authored six of those documents. A stock assessment of dusky shark, a prohibited species under the shark FMP and candidate for listing under the ESA, is under way with expected completion in summer of 2006. Biological and fishery information available for this species is being synthesized and stock status will be evaluated using multiple stock assessment methodologies. The next assessment of large coastal sharks is planned for FY06, but data collection, synthesis, analysis, and preliminary stock evaluations will begin in late FY05.

Update on Catches of Atlantic Sharks

An update on catches of large and small coastal and pelagic sharks in U.S. Atlantic, Gulf of Mexico, and Caribbean waters was generated in FY 05 for inclusion in the 2005 SAFE Annual Report and future shark stock assessments. Time series of commercial and recreational landings and discard estimates from several sources were compiled for the large coastal shark complex and sandbar and blacktip sharks. In addition, recent species-specific commercial and recreational landings were provided for sharks in the large coastal, small coastal, and pelagic groups. Species-specific information on the geographical distribution of commercial landings by gear type and geographical distribution of the recreational catches was also provided. Trends in length-frequency distributions and average weights and lengths of selected species reported from three separate recreational surveys and in the directed shark bottom-longline observer program were also included. Another update on catches of Atlantic sharks will be generated in FY 06.

Ecosystem Modeling

A dynamic mass-balance ecosystem model was used to investigate how relative changes in fishing mortality on sharks can affect the structure and function of Apalachicola Bay, Florida, a coastal marine ecosystem. Simulations were run for 25 years wherein fishing mortality rates from recreational and trawl fisheries were doubled for ten years and then decreased to initial levels. Effect of time/area closures on ecosystem components were also tested by eliminating recreational fishing mortality on juvenile blacktip sharks. Simulations indicated biomass of sharks declined up to 57 percent when recreational fishing mortality was doubled. Simulating a time/area closure for juvenile blacktip sharks caused increases in their biomass but decreases in juvenile coastal shark biomass, a competing multispecies assemblage that is the apparent competitor. In general, reduction of targeted sharks did not cause strong top-down cascades. Another update on catches of Atlantic sharks was generated in FY05

Elasmobranch Feeding Ecology and Shark Diet Database

The current Fishery Management Plan for Atlantic Tunas, Swordfish, and Sharks gives little consideration to ecosystem function because there is little quantitative species-specific data on diet, competition, predator-prey interactions, and habitat requirements of sharks. Given this, several studies are currently underway describing the diet and foraging ecology, habitat use, and predator-prey interactions of elasmobranchs in various communities. In 2005, a study on latitudinal variation in diet and daily ration of the bonnethead shark from the eastern Gulf of Mexico was completed and a manuscript is being prepared for publication. A database containing information on quantitative food and feeding studies of sharks conducted around the world has been in development for several years and presently includes over 200 studies. This fully searchable database will continue to be updated and fine-tuned in FY 06. The goal is to make this tool available to researchers in the relatively near future.

Cooperative Gulf of Mexico States Shark Pupping and Nursery Survey (GULFSPAN)

The SEFSC Panama City Shark Population Assessment Group manages and coordinates a survey of coastal bays and estuaries between the Panhandle of Florida and Texas. Surveys identify the presence/absence of neonate and juvenile sharks and attempt to quantify the relative importance of each area as it pertains to essential fish habitat requirements for sharks. The SEFSC Panama City Shark Population Assessment Group also initiated a juvenile shark abundance index survey in 1996. The index is based on random, depth-stratified gillnet sets conducted throughout coastal bays and estuaries in northwest Florida monthly from April to October. The species targeted for the index of abundance are juvenile sharks in the large and small coastal management groups. More information on this program can be found in Section 3.3 of this document.

Angel Shark Life History

The Atlantic Angel Shark is a benthic species inhabiting deep waters of the Gulf of Mexico and the Atlantic Ocean. This species is listed as prohibited by the 1999 Fisheries Management Plan for Atlantic Tunas, Swordfish, and Sharks due to the lack of biological data and a precautionary approach for species thought to be highly susceptible to exploitation. Life history studies began in 2003. Samples are obtained from commercial fishers and fishery-independent surveys. Preliminary reproductive parameters were determined in 2004 and results presented at the annual American Elasmobranch Society meeting held in Norman, Oklahoma, in May 2004.

Life History Studies of Elasmobranchs

Biological samples are obtained through research surveys and cruises, recreational fishers, and through collection by onboard observers on commercial fishing vessels. Age and growth rates and other life history aspects of selected species are processed and data analyzed following standard methodology. This information is vital as input to population models incorporating variation and uncertainty in estimates of life-history traits to predict the productivity of the stocks and ensure that they are harvested at sustainable levels. The age and growth parameters of bull shark (*Carcharhinus leucas*) and spinner shark (*C. brevipinna*) were completed and submitted for publication in 2004.

Cooperative Research – Definition of Winter Habitats for Blacktip Sharks in the Eastern Gulf of Mexico

A collaborative effort between SEFSC Panama City Shark Population Assessment Group and Mote Marine Laboratory is underway to define essential winter habitats for blacktip sharks (*Carcharhinus limbatus*). Deployment of archival Pop-Up Archival Transmitting (PAT) tags on sharks during January and February of FY05 in the Florida Keys and north Florida will be executed with the cooperation of the charterboat industry. PAT tags will be programmed to detach from individuals during late spring and early summer when sharks have recruited to coastal areas.

Cooperative Research – Habitat Utilization among Coastal Sharks

Through a collaborative effort between SEFSC Panama City Shark Population Assessment Group and Mote Marine Laboratory, the utilization of coastal habitats by neonate and young-of-the-year blacktip and Atlantic sharpnose sharks will be monitored through an array of underwater acoustic receivers (VR2, Vemco Ltd.) placed throughout each study site. Movement patterns, home ranges, activity space, survival, and length of residence of individuals will be compared by species and area to provide information to better manage critical species and essential fish habitats.

Cooperative Research – Characterization of Bycatch in the Gulf Butterfish, (*Peprilus burti*), Trawl Fishery, with an Emphasis on Identification of Life History Parameters for several Potentially High-Risk Species

A proposal with the SEFSC Panama City Shark Population Assessment Group and the University of Florida was submitted to MARFIN to quantify and qualify the elasmobranch bycatch in the butterfish, (*Peprilus triacanthus)*, trawl fishery in the Gulf of Mexico. Determination of life history parameters for the roundel skate, (*R. texana)*, the clearnose skate, (*R. eglanteria)*, the spreadfin skate (*Dipturus olseni)*, and the Atlantic angel shark, (*Squatina dumerili)* will be developed ultimately for the estimation of vital rates. Vital rate information will be used to determine the productivity of the stocks and ensure that they are harvested at sustainable levels.

Using elemental chemistry of shark vertebrae to reconstruct large-scale movement patterns of sharks

A project examining ontogenetic shifts in habitat utilization of bull sharks using Sr:Ca ratios of vertebrae will begin in FY06, funds permitting. Laser ablation ICPMS will be used to assay transects across the entire vertebral section along the corpus calcareum. Given the relationship of Sr:Ca to habitat developed from the reference samples, habitat type (freshwater, estuarine, or marine) will be assigned to each growth band, thereby reconstructing the migration history of the shark on a year-by-year basis over its lifetime.

Coastal Shark Assessment Research Surveys

The SEFSC Mississippi Laboratories in Pascagoula have been operating annual research cruises aboard NOAA vessels since 1995. The objectives of this program are to conduct bottom longline surveys to assess the distribution and relative abundance of coastal sharks along U.S. and Mexican waters of the Gulf of Mexico and the U.S. eastern seaboard. This is the only long-term, nearly stock-wide, fishery-independent survey of Atlantic sharks conducted in U.S. and neighboring waters. Ancillary objectives are to collect biological and environmental data, and to tag-and-release sharks. Starting in 2001 and under the auspices of the Mex-US-Gulf Program, the Pascagoula Laboratories have provided logistical and technical support to Mexico's Instituto Nacional de la Pesca to conduct a cooperative research cruise aboard the Mexican research vessel Onjuku in Mexican waters of the Gulf of Mexico. The cruise also took place in 2002, but was suspended in 2003 and 2004 because of mechanical problems with the research vessel and other issues.

A proposal was submitted in 2005 to gather data to help clarify the uncertainty on the current status of oceanic whitetip sharks in the western North Atlantic Ocean. Data on behavior and movement patterns will be collected using on-board observers on pelagic longline vessels. Archival satellite pop-up tags will be utilized to monitor the movement patterns, depth, and temperature preferences of this species. In addition, time-depth recorders, and hook-timers will be used to determine the depth and times at which sharks take baits. These data will be incorporated with sea surface temperature data from satellites and incorporated into new habitat-based analyses of the data to provide a better understanding of the status of oceanic whitetip sharks.

Cooperative Research – The capture depth, time, and hooked survival rate for bottom longline-caught large coastal sharks

A collaborative effort between SEFSC Panama City Shark Population Assessment Group and the University of Florida to examine alternative measures in the shark bottom longline fishery to reduce mortality on prohibited sharks such as reduced soak time, restrictions on the length of gear, and fishing depth restrictions will be tested using hook timers. Funding is being sought through the NMFS Cooperative Research Program.

Utilizing Bioenergetics and Matrix Projection Modeling to Quantify Population Fluctuations in Long-lived Elasmobranchs: Tools for Fisheries Conservation and Management

Under the supervision of SEFSC scientists at the Panama City Laboratory, the NMFS-Sea Grant Fellow in Population Dynamics and Resource Economics conducted research that sought to use a bioenergetics and matrix approach to examine the population dynamics of the cownose ray (*Rhinoptera bonasus*). Laboratory experiments and field data were used to obtain basic life history information, and that information configured the individual-based bioenergetics model. The bioenergetics model was coupled to a matrix projection model, and the coupled models were used to predict how warmer and cooler water temperatures would affect the growth and population dynamics of the cownose rays. Changes in growth rates under the warmer and cooler conditions lead to changes in age-specific survivorship, maturity, and pup production, which were used as inputs to a matrix projection model. Faster growth of individuals under the cooler scenarios translated into an increased population growth rate (4.4 – 4.7 percent/year versus 2.7 percent/year under baseline), shorter generation time, and higher net reproductive rates, while slower growth under the warmer scenarios translated into slower population growth rate (0.05 – 1.2 percent/year), longer generation times, and lower net reproductive rates. Elasticity analysis indicated that population growth rate was most sensitive to adult survival. Reproductive values by age were highest for intermediate ages.

Cooperative Research – Definition of Winter Habitats for Blacktip Sharks in the Eastern Gulf of Mexico

A collaborative effort between SEFSC Panama City Shark Population Assessment Group and Mote Marine Laboratory is underway to define essential winter habitats for blacktip sharks (*Carcharhinus limbatus*). Deployment of two pop-off satellite archival tags (PAT) on sharks during January and February of 2005 in the Florida Keys was accomplished with the cooperation of the charter boat industry. Preliminary results from these two sharks indicate one shark remained in the Keys while the other moved to an area southwest of the coast of Cuba. Additional PAT tags will be placed on sharks during the summer of 2005.

Cooperative Research – Definition of Summer Habitats and Migration Patterns for Bull Sharks in the Eastern Gulf of Mexico

A collaborative effort between SEFSC Panama City Shark Population Assessment Group, University of Florida, and Mote Marine Laboratory is underway to determine summer habitat use and short-term migration patterns of bull sharks (*Carcharhinus leucas*). Sharks are being outfitted with Pop-Up Satellite Archival Tags (PSAT) during July and August of 2005 and scheduled to deploy in autumn. This project is driven by the lack of data for this species and its current prominence within the Florida coastal community. A better understanding of this species is required to effectively manage this species for both commercial and recreational fishers as well as the general public. Concerns regarding this species will continue to be an issue as fishers and the public demand that state and federal governments provide better information concerning the presence and movements of these sharks.

## 3.3 Habitat

### 3.3.1 Regulatory Requirements

Section 303(a)(7) of the Magnuson-Stevens Act, 16 U.S.C. §§ 1801 *et seq*., as amended by the Sustainable Fisheries Act in 1996, requires FMPs to describe and identify essential fish habitat (EFH), minimize to the extent practicable adverse effects on such habitat caused by fishing, and identify other actions to encourage the conservation and enhancement of such habitat. The Magnuson-Stevens Act defines EFH as “those waters and substrate necessary to fish for spawning, breeding, feeding or growth to maturity.” (16 U.S.C. § 1802 (10)). The EFH regulations (at 50 C.F.R. 600 Subpart J) provide additional interpretation of the definition of essential fish habitat:

> “Waters’ include aquatic areas and their associated physical, chemical, and biological properties that are used by fish, and may include aquatic

> areas historically used by fish where appropriate; 'substrate' includes sediment, hard bottom, structures underlying the waters, and associated biological communities; 'necessary' means the habitat required to support a sustainable fishery and the managed species' contribution to a healthy ecosystem; and 'spawning, breeding, feeding, or growth to maturity' covers a species' full life cycle."

The EFH regulations require that EFH be described and identified within the U.S. Exclusive Economic Zone (EEZ) for all life stages of each species in a fishery management unit. FMPs must describe EFH in text, tables, and figures that provide information on the biological requirements for each life history stage of the species. According to the EFH regulations, an initial inventory of available environmental and fisheries data sources should be undertaken to compile information necessary to describe and identify EFH and to identify major species-specific habitat data gaps. Habitats that satisfy the criteria in the Magnuson-Stevens Act have been identified and described as EFH in the 1999 FMPs and in Amendment 1 to the 1999 Tunas, Swordfish, and Shark FMP.

NMFS originally described and identified EFH and related EFH regulatory elements for all HMS in the management unit in the 1999 FMPs, and more recently updated EFH for five shark species (blacktip, sandbar, dusky, nurse, and finetooth sharks) in Amendment 1 to the 1999 Tunas, Swordfish, and Shark FMP, which was implemented in 2003. The EFH regulations further require NMFS to conduct a comprehensive review of all EFH related information at least once every five years and revise or amend the EFH boundaries if warranted. To that effect, NMFS is currently undertaking the comprehensive five-year review of information pertaining to EFH for all HMS in the management unit in this draft FMP. Based on the findings of this review, NMFS may recommend that certain EFH boundaries may need to be modified in a subsequent rulemaking. At that time, alternatives for boundary modifications would be proposed. For a complete description of the comprehensive five-year review of all new EFH information see Chapter 10 and Appendix B.

#### 3.3.1.1 Habitat Areas of Particular Concern

To further the conservation and enhancement of EFH, the EFH guidelines encourage FMPs to identify Habitat Areas of Particular Concern (HAPCs). HAPCs are areas within EFH that meet one or more of the following criteria: they are ecologically important, particularly vulnerable to degradation, undergoing stress from development, or are a rare habitat type. HAPCs can be used to focus conservation efforts on specific habitat types that are particularly important to managed species. Currently, only one area, for sandbar sharks off of North Carolina, Chesapeake Bay, MD, and Great Bay, NJ, has been identified as a HAPC for HMS (1999 FMP). Although no new HAPCs have been identified since the 1999 FMP, and no new HAPCs are proposed in this draft FMP, the information being compiled during this review may be used to identify HAPC areas in a future rulemaking.

### 3.3.2 Habitat Types and Distributions

HMS may be found in large expanses of the world's oceans, straddling jurisdictional boundaries. Although many of the species frequent other oceans of the world, the Magnuson-

Stevens Act only authorizes the description and identification of EFH in Federal, state or territorial waters, including areas of the U.S. Caribbean, the Gulf of Mexico and the Atlantic coast of the United States to the seaward limit of the U.S. EEZ. These areas are connected by currents and water patterns that influence the occurrence of HMS at particular times of the year. On the largest scale, the North and South Equatorial currents occur in the U.S. Caribbean islands. The North Equatorial Current continues through the Caribbean Basin to enter the Gulf of Mexico through the Yucatan Straits. The current continues through the Florida Straits to join the other water masses (including the Antilles Current) to form the Gulf Stream along the eastern coast of the United States. Variations in flow capacities of the Florida Straits and the Yucatan Straits produce the Loop Current, the major hydrographic feature of the Gulf of Mexico. These water movements in large part influence the distributions of the pelagic life stages of HMS.

Tuna, swordfish, and billfish distributions are most frequently associated with hydrographic features such as density fronts between different water masses. The scales of these features may vary. For example, the river plume of the Mississippi River extends for miles into the Gulf of Mexico and is a fairly predictable feature, depending on the season. Fronts that set up over the De Soto Canyon in the Gulf of Mexico, or over the Charleston Bump or the Baltimore Canyon in the Mid-Atlantic, may be of a much smaller scale. The locations of many fronts or frontal features are statistically consistent within broad geographic boundaries. These locations are influenced by riverine inputs, movement of water masses, and the presence of topographic structures underlying the water column, thereby influencing the habitat of HMS. Those areas that are known spawning grounds, or areas of aggregation for feeding or other reasons, are considered to be EFH for those species.

Sharks are found in a wide variety of coastal and ocean habitats including estuaries, nearshore areas, the continental shelf, continental slope, and open ocean. Many species are migratory and, like other marine species, are affected by the condition of the habitat. Atlantic sharks are broadly distributed as adults but have been found to utilize specific estuaries as pupping and nursery areas during pupping season and throughout their neonate (newborn) life stages which may vary from a few to many months. Since coastal and coastal pelagic species frequently appear near shore and have pupping and nursery areas near shore, much more is known about their habitat requirements, particularly for early life history stages. Much less is known about the habitat requirements, pupping areas, and other details of pelagic and deep dwelling species.

The following sections are intended to provide a general overview of the various habitats with which HMS are most frequently associated. A more detailed description is contained in the 1999 Tunas, Swordfish, and Shark FMP.

#### 3.3.2.1 Atlantic Ocean

(Material in this section is largely a summary of information in MMS, 1992; 1996. Original sources of information are referenced in those documents)

The region of the Atlantic Ocean within which EFH for Federally managed HMS is identified spans the area between the Canadian border in the north and the Dry Tortugas in the south. It includes a diverse spectrum of aquatic species of commercial, recreational, and ecological importance. The distribution of marine species along the Atlantic seaboard is strongly affected by the cold Labrador Current in the northern part, the warm Gulf Stream in the middle and southern portions of the region, and generally by the combination of high summer and low winter temperatures. For many species Cape Hatteras forms a strong zoogeographic boundary between the Mid- and South Atlantic areas, while the Cape Cod/Nantucket Island area is a somewhat weaker zoogeographic boundary in the north.

*Coastal and Estuarine Habitat*

Although HMS move primarily through open ocean waters, they do periodically utilize coastal or inshore habitats. This is especially true for several species of sharks that move inshore, often into shallow coastal waters and estuaries, to give birth; these areas then become nursery areas as the young develop. Examples include Great Bay, New Jersey, Chesapeake Bay, Maryland and Delaware Bay, Delaware which provide important nursery habitat for sandbar sharks, and Bull's Bay, South Carolina, and Terrebone Bay, Louisiana which are important blacktip shark nursery areas. Typically, the pups (neonates) remain in these same areas throughout their early life stages, which may vary from a few to many months. Recent tagging studies have shown that some sharks return to summer nursery areas in subsequent years. Although billfish move primarily throughout open-ocean waters, two species, the white marlin and the sailfish can be found inshore. Sailfish are also known to move inshore to spawn off the east coast of Florida and in the Florida Keys.

Coastal habitats that may be encountered by HMS are described in this section. Those areas that are known nursery or spawning grounds, or areas of HMS aggregation for feeding or other reasons, are considered to be EFH for those species. It should be noted that characteristics of coastal and offshore habitats may be affected by activities and conditions occurring outside of those areas (farther up-current) due to water flow or current patterns that may transport materials that could cause negative impacts.

Estuaries are highly productive, yet fragile, environments that support a great diversity of fish and wildlife species, including sharks. Many commercially valuable fish and shellfish stocks are dependent on these areas during some stage of their development. In the vicinity of North Carolina, Virginia, and Maryland, approximately 90 percent of the commercially valuable fish species are dependent on estuaries for at least part of their life cycle.

Along the Atlantic seaboard coastal wetlands are located predominantly south of New York because these coastal areas have not been glaciated. Nearly 75 percent of the Atlantic coast salt marshes are found in the states of North Carolina, South Carolina, and Georgia. These three states contain approximately nine million acres of salt marsh. Wetland vegetation plays an important role in nutrient cycling, and provides stability to coastal habitats by preventing the erosion of sediments and by absorbing the energy of storms.

There are 13,900 square miles (sq mi) (36,000 square kilometers (sq km)) of estuarine habitat along the Atlantic coast, of which approximately 68 percent (9,400 sq mi) occurs north of the Virginia/ North Carolina border, with Chesapeake Bay contributing significantly to the total. South of the Gulf of Maine, where there is a wider coastal plain and greater agricultural activity, estuaries carry higher sediment and nutrient loads. The increased fertility and generally higher water temperatures resulting from these nutrient loads allow these estuaries to support greater numbers of fish and other aquatic organisms.

South of the Virginia/North Carolina border, there are approximately 4,500 sq mi (11,655 sq km) of estuarine habitat. The Currituck, Albemarle, and Pamlico Sounds, which together constitute the largest estuarine system along the entire Atlantic coast, make up a large portion of these southern estuaries. A unique feature of these sounds is that they are partially enclosed and protected by a chain of fringing islands, the Outer Banks, located 32 to 48 km (20 to 30 mi) from the mainland.

Because of their low tidal flushing rates, estuaries are generally more susceptible to pollution than other coastal water bodies. The severity of the problem varies depending on the extent of tidal flushing. In Maryland and Virginia, the primary problems reported are excessive nutrients (nitrates and phosphates), particularly in the Chesapeake Bay and adjoining estuarine areas. Other problems included elevated bacterial and suspended sediment levels. Non-point sources of pollution are considered one of the main causes of pollution. Elevated bacterial levels were also listed as a local coastal pollution problem in Maryland.

In North Carolina, the primary problems occurring in estuarine areas are enrichment in organics and nutrients, fecal coliform bacteria, and low dissolved oxygen. Insufficient sewage treatment, wide-spread use of septic systems in coastal areas, and agricultural runoff are considered to be major causes of these pollution problems. Oil spills from vessel collisions and groundings, as well as illegal dumping of waste oil, are a common cause of local, short-term water quality problems, especially in estuaries along the North and Mid-Atlantic coasts. These sources of pollution and habitat degradation may have a negative impact on coastal shark populations, particularly during vulnerable early life stages.

Many of the coastal bays and estuaries along the Atlantic East Coast and Gulf of Mexico are described in greater detail in the 1999 Tunas, Swordfish, and Shark FMP, including the distribution, size, depth, freshwater inflow, habitat types, tidal range and salinity for each of the major estuaries and bays on the East coast and Gulf coast, and are not repeated here.

*Continental Shelf and Slope Areas*

Moving seaward away from the coast, the next major geologic features encountered are the continental shelf and slope areas. The continental shelf is characterized by depths ranging from a few meters to approximately 60 m (198 ft), with a variety of bottom habitat types. Far less research has been done in this area than on the coasts and estuaries, and consequently much less is known about the specific habitat requirements of HMS within these regions.

The shelf area of the Mid-Atlantic Bight averages about 100 km (60 mi) in width, reaching a maximum of 150 km (90 mi) near Georges Bank, off New England, and a minimum of 50 km (30 mi) offshore Cape Hatteras, NC. Current speeds are strongest at the narrowest part of the shelf where wind-driven current variability is highest. The distribution of marine species, including HMS, along the Atlantic seaboard may be strongly influenced by currents, the warm Gulf Stream in the middle and south portions of the region, and generally by the combination of high summer and low winter temperatures.

The continental shelf in the South Atlantic Bight varies in width from 50 km (32 mi) off Cape Canaveral, FL to a maximum of 120 km (75 mi) off Savannah, GA, and a minimum of 30 km (19 mi) off Cape Hatteras. The shelf is divided into three cross-shelf zones. Waters on the inner shelf (0 to 20 m (0 to 66 ft)) interact extensively with rivers, coastal sounds, and estuaries. This interaction tends to form a band of low-salinity, stratified water near the coast that responds quickly to local wind-forcing and seasonal atmospheric changes. Mid-shelf (20 – 40 m (66 – 132 ft)) current flow is strongly influenced by local wind events with frequencies of two days to two weeks. In this region, vertically well mixed conditions in fall and winter contrast with vertically stratified conditions in the spring and summer. Gulf Stream frontal disturbances (*e.g.*, meanders and cyclonic cold core rings) that occur on time scales of two days to two weeks dominate currents on the outer shelf (40 to 60 m (132 to 197 ft)).

The Mid-Atlantic area from Cape Cod, MA to Cape Hatteras, NC represents a transition zone between northern cold-temperate waters of the north and the warm-temperate waters to the south. Water temperatures in the Mid-Atlantic vary greatly by season. Consequently, many of the fish species of importance in the Mid-Atlantic area migrate seasonally, whereas the major species in the other three areas are typically resident throughout the year (MMS, 1992; 1996). The shelf-edge habitat may range in water depth between 40 and 100 m (131 and 328 ft). The bottom topography varies from smooth sand to mud to areas of high relief with associated corals and sponges. The fish species found in this area include parrotfish (*Scaridae*) and the deep-water species of the snapper-grouper assemblage.

The continental slope generally has smooth mud bottoms in water depths of 100 to 200 m (328 to 656 ft). Many of the species in this zone are representatives of cold-water northern species exhibiting tropical submergence (*i.e.*, being located in deeper, cooler water as latitude decreases).

A topographic irregularity southeast of Charleston, SC, known as the Charleston Bump, is an area of productive sea floor, which rises abruptly from 700 – 300 m (2,300 – 980 ft) within a distance of about 20 km (12 mi), and at an angle which is approximately transverse to both the general isobath pattern and the Gulf Stream currents. The Charleston Gyre is a persistent oceanographic feature that forms in the lee of the Charleston Bump. It is a location in which larval swordfish have been commonly found and may serve as nursery habitat.

*Pelagic Environment*

Many HMS spend their entire lives in the pelagic, or open ocean environment. These species are highly mobile and physiologically adapted to traveling great distances with minimal effort. Much of what is known about the association between HMS and their migrations across vast open ocean habitat comes from tagging studies.

While the open ocean may appear featureless, there are major oceanographic features such as currents, temperature gradients, eddies, and fronts that occur on a large scale and may influence the distribution patterns of many oceanic species, including HMS. For instance, the Gulf Stream produces meanders, filaments, and warm and cold core rings that significantly affect the physical oceanography of the continental shelf and slope. These features tend to aggregate both predators and prey, and are frequently targeted by commercial fishing vessels. This western boundary current has its origins in the tropical Atlantic Ocean (*i.e.*, the Caribbean Sea). The Gulf Stream system is made up of the Yucatan Current that enters the Gulf of Mexico through the Yucatan Straits; the Loop Current which is the Yucatan Current after it separates from Campeche Bank and penetrates the Gulf of Mexico in a clockwise flowing loop; the Florida Current, as it travels through the Straits of Florida and along the continental slope into the South Atlantic Bight; and the Antilles Current as it follows the continental slope (Bahamian Bank) northeast to Cape Hatteras. From Cape Hatteras it leaves the slope environment and flows into the deeper waters of the Atlantic Ocean.

The flow of the Gulf Stream as it leaves the Straits of Florida reaches maximum speeds of about 200 cm/s. During strong events, maximum current speeds greater than 250 cm/s have been recorded offshore of Cape Hatteras. The width of the Gulf Stream at the ocean surface ranges from 80 – 100 km (50 – 63 mi) and extends to depths of between 800 and 1,200 m (2,624 – 3,937 ft).

As a meander passes, the Gulf Stream boundary oscillates sequentially onshore (crest) and offshore (trough). A meander can cause the Gulf Stream to shift slightly shoreward or well offshore into deeper waters. The Gulf Stream behaves in two distinct meander modes (small and large), with the size of the meanders decreasing as they move northward along the coast. During the large meander mode the Gulf Stream front is seaward of the shelf break, with its meanders having large amplitudes. Additionally, frontal eddies and accompanying warm-water filaments are larger and closer to shore. During the small meander mode the Gulf Stream front is at the shelf break. Frontal eddies and warm-water filaments associated with small amplitude meanders are smaller and farther from shore. Since HMS tend to follow the edge of the Gulf Stream, their distance from shore can be greatly influenced by the patterns of meanders and eddies.

Meanders have definite circulation patterns and conditions superimposed on the statistical mean (average) condition. As a meander trough migrates in the direction of the Gulf Stream's flow, it upwells cool nutrient-rich water, which at times may move onto the shelf and may evolve into an eddy. These boundary features move south-southwest. As warm-water filaments, they transfer momentum, mass, heat, and nutrients to the waters of the shelf break.

Gulf Stream filaments are mesoscale events, which occur regularly offshore the southeast United States. The filament is a tongue of water extending from the Gulf Stream pointing to the south. These form when meanders cause the extrusion of a warm surface filament of Gulf Stream water onto the outer shelf. The cul-de-sac formed by this extrusion contains a cold core that consists of a mix of outer-shelf water and nutrient-rich water. This water mix is a result of upwelling as the filament/meander passes along the slope. The period from genesis to decay typically is about two to three weeks.

The Charleston Gyre is a permanent oceanographic feature of the South Atlantic Bight, caused by the interaction of the Gulf Stream waters with the topographically irregular Charleston Bump. The gyre produces an upwelling of nutrients, which contributes significantly to primary and secondary productivity of the Bight. The degree of upwelling varies with the seasonal position and velocity of the Gulf Stream currents.

In the warm waters between the west edge of the Florida Current/Gulf Stream and 20° N and 40° N, pelagic brown algae, *Sargassum natans* and *S. fluitans*, form a dynamic structural habitat. The greatest concentrations are found within the North Atlantic Central Gyre in the Sargasso Sea. Large quantities of *Sargassum* frequently occur on the continental shelf off the southeastern United States. Depending on prevailing surface currents, this material may remain on the shelf for extended periods, be entrained into the Gulf Stream, or be cast ashore. During calm conditions *Sargassum* may form irregular mats or simply be scattered in small clumps. Oceanographic features such as internal waves and convergence zones along fronts aggregate the algae along with other flotsam into long linear or meandering rows collectively termed "windrows."

Pelagic *Sargassum* supports a diverse assemblage of marine organisms including fungi, micro- and macro-epiphytes, sea turtles, numerous marine birds, at least 145 species of invertebrates, and over 100 species of fishes. The fishes associated with pelagic *Sargassum* include juveniles as well as adults, including large pelagic adult fishes. Swordfish and billfish are among the fishes that can be found associated with *Sargassum*. The *Sargassum* community, consisting of the floating *Sargassum* (associated with other algae, sessile and free-moving invertebrates, and finfish) is important to some epipelagic predators such as wahoo and dolphin. The *Sargassum* community provides food and shelter from predation for juvenile and adult fish, including HMS, and may have other functions such as habitat for fish eggs and larvae.

Offshore water quality in the Atlantic is controlled by oceanic circulation, which, in the Mid-Atlantic is dominated by the Gulf Stream and by oceanic gyres. A shoreward, tidal and wind-driven circulation dominates as the primary means of pollutant transport between estuaries and the nearshore. Water quality in nearshore water masses adjacent to estuarine plumes and in water masses within estuaries is also influenced by density-driven circulation. Suspended sediment concentration can also be used as an indication of water quality. For the Atlantic coastal areas, suspended sediment concentration varies with respect to depth and distance from shore, the variability being greatest in the Mid-Atlantic and South Atlantic. Re-suspended bottom sediment is the principal source of suspended sediments in offshore waters.

#### 3.3.2.2 Gulf of Mexico

(Material in this section is largely a summary of information in MMS, 1996; Field *et al.*, 1991; and NOAA 1997. Original sources of information are referenced in those documents.)

The Gulf of Mexico supports a great diversity of fish resources that are related to a variety of ecological factors, such as salinity, primary productivity, and bottom type. These factors differ widely across the Gulf of Mexico and between inshore and offshore waters. Characteristic fish resources are not randomly distributed; high densities of fish resources are associated with particular habitat types (*e.g.*, east Mississippi Delta area, Florida Big Bend sea grass beds, Florida Middle Grounds, mid-outer shelf, and the De Soto Canyon area). The highest values of surface primary production are found in the upwelling area north of the Yucatan Channel and in the De Soto Canyon region. In terms of general biological productivity, the western Gulf is considered to be more productive in the oceanic region than is the eastern Gulf. Productivity of areas where HMS are known to occur varies between the eastern and western Gulf, depending on the influence of the Loop Current.

*Coastal and Estuarine Habitats*

There are 5.62 million hectares (ha) (13.88 million acres) of estuarine habitat among the five states bordering the Gulf. This includes 3.2 million ha (8 million acres) of open water, 2.43 million ha (6 million acres) of emergent tidal vegetation (including about 162,000 ha (400,318 acres) of mangroves), and 324,000 ha (800, 636 acres) of submerged vegetation. Estuaries are found from east Texas through Louisiana, Mississippi, Alabama, and northwest Florida and encompass more than 62,000 sq km (23,938 sq mi) of water surface area. Estuaries of the Gulf of Mexico export considerable quantities of organic material, thereby enriching the adjacent continental shelf areas, and many of these estuaries provide important habitat as pupping and nursery grounds for juvenile stages of many important invertebrate and fish species including many species of Atlantic sharks.

Coastal wetland habitat types that occur along the Gulf Coast include mangroves, non-forested wetlands (fresh, brackish, and saline marshes), and forested wetlands. Marshes and mangroves form an interface between marine and terrestrial habitats, while forested wetlands occur inland from marsh areas. Wetland habitats may occupy narrow bands or vast expanses, and can consist of sharply delineated zones of different species, monospecific stands of a single species, or mixed plant species communities.

*Continental Shelf and Slope Areas*

The Gulf of Mexico is a semi-enclosed, subtropical sea with a surface area of approximately 1.6 million sq km (0.6 million sq mi). The main physiographic regions of the Gulf basin are the continental shelf, continental slope and associated canyons, the Yucatan and Florida Straits, and the abyssal plains. The U.S. continental shelf is narrowest, only 16 km (9.9 mi) wide, off the Mississippi River. The continental shelf width varies significantly from about 350 km (217 mi) offshore western Florida, 156 km (97 mi) off Galveston, TX, and decreasing to 88 km (55 mi) off Port Isabel near the Mexican border. The depth of the central abyss ranges to 4,000 m (13,000 ft). The Gulf is unique because it has two entrances: the Yucatan Strait and the Straits of Florida. The Loop Current dominates the Gulf's general circulation and its associated eddies. The Loop current is caused by differences between the sill depths of the two straits. Coastal and shelf circulation, on the other hand, is driven by several forcing mechanisms: wind stress, freshwater input, buoyancy and mass fluxes, and transfer of momentum and energy through the seaward boundary.

In the Gulf, the continental shelf extends seaward from the shoreline to about the 200-m water depth (660 ft), and is characterized by a gentle slope of less than one degree. The continental slope extends from the shelf edge to the continental rise, usually at about the 2,000-m (6,500 ft) water depth. The topography of the slope in the Gulf is uneven and is broken by canyons, troughs, and escarpments. The gradient on the slope is characteristically one to six degrees, but may exceed 20 degrees in some places, particularly along escarpments. The continental rise is the apron of sediment accumulated at the base of the slope. The incline is gentle with slopes of less than one degree. The abyssal plain is the basin floor at the base of the continental rise.

*Physical Oceanography*

The Gulf receives large amounts of freshwater runoff from the Mississippi River as well as from a host of other drainage systems. In recent years, large amount of nutrient laden runoff from the Mississippi River have resulted in large hypoxic or low oxygen areas in the Gulf. This "dead zone" may affect up to 16,500 sq km (6,371 sq mi) during the summer, resulting in unfavorable habitat conditions for a wide variety of species.

Sea-surface temperatures in the Gulf range from nearly constant throughout (isothermal) (29° to 30°C (84° to 86°F)) in August to a sharp horizontal gradient in January, (25°C (77°F) in the Loop Current core to 14° to 15°C (57° to 59°F) along the northern shelf). The vertical distribution of temperature reveals that in January, the thermocline depth is about 30 to 61 m (98 to 200 ft) in the northeast Gulf and 91 to 107 m (298 to 350 ft) in the northwest Gulf. In May, the thermocline depth is about 46 m (150 ft) throughout the entire Gulf.

Sea surface salinities along the north Gulf vary seasonally. During months of low freshwater input, salinities near the coastline range between 29 to 32 ppt. High freshwater input conditions during the spring and summer months result in strong horizontal gradients and inner shelf salinities less than 20 ppt. The mixed layer in the open Gulf, from the surface to a depth of approximately 100 to 150 m (330 to 495 ft), is characterized by salinities between 36.0 and 36.5 ppt.

Sharp discontinuities of temperature and/or salinity at the sea surface, such as the Loop Current front or fronts associated with eddies or river plumes, are dynamic features that may act to concentrate buoyant material such as detritus, plankton, or eggs and larvae. These materials are transported, not by the front's movements or motion across the front, but mainly by lateral movement along the front. In addition to open ocean fronts, a coastal front, which separates turbid, lower salinity water from the open-shelf regime, is probably a permanent feature of the north Gulf shelf. This front lies about 30 – 50 km (19 – 31 mi) offshore. In the Gulf, these fronts are the most commonly utilized habitat of the pelagic HMS species.

The Loop Current is a highly variable current entering the Gulf through the Yucatan Straits and exiting through the Straits of Florida (as a component of the Gulf Stream) after tracing an arc that may intrude as far north as the Mississippi-Alabama shelf. This current has been detected down to about 1,000 m (3,300 ft) below the surface. Below that level there is evidence of a countercurrent. When the Loop Current extends into or near shelf areas, instabilities, such as eddies, may develop that can push warm water onto the shelf or entrain cold water from the shelf. These eddies consist of warm water rotating in a clockwise fashion. Major Loop Current eddies have diameters on the order of 300 – 400 km (186 – 249 miles), and may extend to a depth of about 1,000 m. Once these eddies are free from the Loop Current, they travel into the western Gulf along various paths to a region between 25° N to 28° N and 93° W to 96° W. As eddies travel westward a decrease in size occurs due to mixing with resident waters and friction with the slope and shelf bottoms. The life of an individual eddy, until its eventual assimilation by regional circulation in the western Gulf, is about one year. Along the Louisiana/Texas slope, eddies are frequently observed to affect local current patterns, hydrographic properties, and possibly the biota of fixed oil and gas platforms or hard bottoms.

Once an eddy is shed, the Loop Current undergoes major dimensional adjustments and reorganization.

#### 3.3.2.3 U.S. Caribbean

(Material in this section is largely a summary of information in Appeldoorn and Meyers, 1993. Original sources of information are referenced in that document.)

The waters of the Caribbean region include the coastal waters surrounding the U.S. Virgin Islands and Puerto Rico. All of these Caribbean islands, with the exception of St. Croix, are part of a volcanic chain of islands formed by the subduction of one tectonic plate beneath another. Tremendously diverse habitats (rocky shores, sandy beaches, mangroves, seagrasses, algal plains, and coral reefs) and the consistent light and temperature regimes characteristic of the tropics are conducive to high species diversity.

The waters of the Florida Keys and southeast Florida are intrinsically linked with the waters of the Gulf of Mexico and the waters of the Caribbean to the west, south, and east, and to the waters of the South Atlantic Bight to the north. These waters represent a transition from insular to continental regimes and from tropical to temperate regimes. This zone, therefore, contains one of the richest floral and faunal complexes.

*Coastal and Estuarine Habitats*

Although the U.S. waters of the Caribbean are relatively nutrient poor, and therefore have low rates of primary and secondary productivity, they display some of the greatest diversity of any part of the South Atlantic region. High and diverse concentrations of biota are found where habitat is abundant. Coral reefs, sea grass beds, and mangrove ecosystems are the most productive of the habitat types found in the Caribbean, but other areas such as soft-bottom lagoons, algal hard grounds, mud flats, salt ponds, sandy beaches, and rocky shores are also important in overall productivity. These diverse habitats allow for a variety of floral and faunal populations.

Offshore, between the sea grass beds and the coral reefs and in deeper waters, sandy bottoms and algal plains dominate. These areas may be sparsely or densely vegetated with a canopy of up to one meter of red and brown algae. Algal plains are not areas of active sand transport. These are algae-dominated sandy bottoms, often covered with carbonate nodules. They occur primarily in deep water (> 15 m, or 50 ft), and account for roughly 70 percent of the area of the insular shelf of the U.S. Virgin Islands. Algal plains support a variety of organisms including algae, sponges, gorgonians, solitary corals, mollusks, fish, and worms, and may serve as critical juvenile habitat for commercially important (and diminishing) species such as queen triggerfish and spiny lobsters.

Coral reefs and other coral communities are some of the most important ecological (and economic) coastal resources in the Caribbean. They act as barriers to storm waves and provide habitat for a wide variety of marine organisms, including most of the economically important species of fish and shellfish. They are the primary source for carbonate sand, and serve as the basis for much of the tourism. Coral communities are made by the build up of calcium carbonate produced by living animals, coral polyps, in symbiosis with a dinoflagellate, known as zooxanthellae. During summer and early fall, most of the coral building organisms are at or near the upper temperature limit for survival and so are living under natural conditions of stress. Further increase in local or global temperature could prove devastating.

Sea grass beds are highly productive ecosystems that are quite extensive in the Caribbean; some of the largest sea grass beds in the world lie beyond the shore on both sides of the Keys. Sea grass beds often occur in close association with shallow-water coral reefs. Seagrasses are flowering plants that spread through the growth of roots and rhizomes. These act to trap and stabilize sediments, reduce shoreline erosion, and buffer coral reefs; they provide food for fish, sea turtles (heavy grazers), conch, and urchins; they provide shelter and habitat for many adult species and numerous juvenile species that rely on the sea grass beds as nursery areas; and they provide attachment surfaces for calcareous algae.

Mangrove habitats are very productive coastal systems that support a wide variety of organisms. The mangrove food web is based largely on the release of nutrients from the decomposition of mangrove leaves, and in part on the trapping of terrestrial material. Red mangroves (*Rhizophora mangle*), with their distinctive aerial prop roots; grow along the shoreline, often in mono-specific stands. The roots of the red mangroves help to trap sediments and pollutants associated with terrestrial runoff and help to buffer the shore from storm waves. Red mangrove forests support a diverse community of sponges, tunicates, algae, larvae, and corals, as well as juvenile and adult fish and shellfish. Black mangroves (*Aveicennia germinans*) and white mangroves (*Laguncularia racemosa*) grow landward of the red mangroves. They also act as important sediment traps. Exposed and sheltered mangrove shorelines are common throughout the U.S. Caribbean.

Throughout the U.S. Caribbean, both rocky shores and sandy beaches are common. While many of these beaches are high-energy and extremely dynamic, buffering by reefs and seagrasses allows some salt-tolerant plants to colonize the beach periphery. Birds, sea turtles, crabs, clams, worms, and urchins use the intertidal areas.

Salt ponds, common in the U.S. Virgin Islands, are formed when mangroves or fringing coral reefs grow or storm debris is deposited, effectively isolating a portion of a bay. The resulting "pond" undergoes significant fluctuations of salinity with changes in relative evaporation and runoff. The biota associated with salt ponds are, therefore, very specialized, and usually somewhat limited. Salt ponds are extremely important in trapping terrestrial sediments before they reach the coastal waters.

*Insular Shelf and Slope Areas*

Puerto Rico and the U.S. Virgin Islands contain a wide variety of coastal marine habitats, including coral and rock reefs, sea grass beds, mangrove lagoons, sand and algal plains, soft bottom areas, and sandy beaches. These habitats are, however, very patchily distributed. Nearshore waters range from zero to 20 m (66 ft) in depth, and outer shelf waters range from 20 to 30 m (66 to 99 ft) in depth, the depth of the shelf break. Along the north coast the insular shelf is very narrow (two to three km wide), seas are generally rough, and few good harbors are present. The coast is a mixture of coral and rock reefs, and sandy beaches. The east coast has an extensive shelf that extends to the British Virgin Islands. Depth ranges from 18 to 30 m (59 to 99 ft). Much of the bottom is sandy, commonly with algal and sponge communities. The southeast coast has a narrow shelf (eight km wide). About 25 km (15.5 mi) to the southeast is Grappler Bank, a small seamount with its summit at a depth of 70 m (231 ft). The central south coast broadens slightly to 15 km (99 mi) and an extensive sea grass bed extends nine kilometers offshore to Caja de Muertos Island. Further westward, the shelf narrows again to just two km (1.2 mi) before widening at the southwest corner to over 10 km (6 mi). The entirety of the southern shelf is characterized by hard or sand-algal bottoms with emergent coral reefs, grass beds, and shelf edge. Along the southern portion of the west coast the expanse of shelf continues to widen, reaching 25 km (15.5 mi) at its maximum. A broad expanse of the shelf is found between 14 and 27 m (46 and 99 ft), where habitats are similar to those of the south coast. To the north, along the west coast, the shelf rapidly narrows to two to three kilometers.

*Physical Oceanography*

U.S. Caribbean waters are primarily influenced by the westward flowing North Equatorial Current, the predominant hydrological driving force in the Caribbean region. It flows from east to west along the northern boundary of the Caribbean plateau and splits at the Lesser Antilles, flowing westward along the north coasts of the islands.

The north branch of the Caribbean Current flows west into the Caribbean Basin at roughly 0.5 m (1.7 ft) per second. It is located about 100 km (62 mi) south of the islands, but its position varies seasonally. During the winter it is found further to the south than in summer. Flow along the south coast of Puerto Rico is generally westerly, but this is offset by gyres formed between the Caribbean Current and the island. The Antilles Current flows to the west along the northern edge of the Bahamas Bank and links the waters of the Caribbean to those of southeast Florida.

Coastal surface water temperatures remain fairly constant throughout the year and average between 26° and 30°C (79° and 86°F). Salinity of coastal waters is purely oceanic and therefore is usually around 36 ppt. However, in the enclosed or semi-enclosed embayments salinity may vary widely depending on fluvial and evaporational influences.

It is believed that no upwelling occurs in the waters of the U.S. Caribbean (except perhaps during storm events) and, since the waters are relatively stratified, they are severely nutrient-limited. In tropical waters nitrogen is the principal limiting nutrient.

## 3.4 Fishery Data Update

In this section, HMS fishery data, with the exception of some data on Atlantic sharks, are analyzed by gear type; Section 3.4.6 provides a summary of landings by species. While HMS fishermen generally target particular species, the non-selective nature of most fishing gears promotes effective analysis and management on a gear-by-gear basis. In addition, issues such as bycatch, and safety are generally better addressed by gear type. A summary of catch statistics can be found in Section 3.4.6 of this document.

The revised list of authorized fisheries (LOF) and fishing gear used in those fisheries became effective December 1, 1999 (64 FR 67511). The rule applies to all U.S. marine fisheries, including Atlantic HMS. As stated in the rule, "no person or vessel may employ fishing gear or participate in a fishery in the exclusive economic zone (EEZ) not included in this LOF without giving 90 days' advance notice to the appropriate Fishery Management Council (Council) or, with respect to Atlantic HMS, the Secretary of Commerce (Secretary)." Acceptable HMS fisheries and authorized gear types for Atlantic tunas, swordfish, and sharks include: swordfish handgear fishery – rod and reel, harpoon, handline, bandit gear; pelagic longline fishery – longline; shark drift gillnet fishery – gillnet; shark bottom longline fishery – longline; shark recreational fishery – rod and reel, handline; tuna purse seine fishery – purse seine; tuna recreational fishery– rod and reel, handline; and tuna handgear fishery – rod and reel, harpoon, handline, bandit gear. For Atlantic billfish, the only acceptable fishery and authorized gear type is recreational fishery – rod and reel. Species whose life history characteristics may lead to their eventual categorization as highly migratory, but which are not currently under the Secretary or Regional Council management authority, are covered in two broad categories: Recreational Fisheries (Non-FMP) and Commercial Fisheries (Non-FMP). Species that fit this description may be harvested with the gears listed for these catchall categories.

Due to the nature of SCRS data collection,

Table 3.21 depicts a summary of U.S. and international HMS catches by species rather than gear type. International catch levels and U.S. reported catches for HMS, other than sharks, are taken from the 2005 Standing Report of the SCRS (SCRS, 2005). The U.S. percentage of regional and total catches for HMS species is presented (

Table 3.21) to provide a basis for comparison of the U.S.' catches relative to other nations/entities. Catch of billfish includes both recreational landings and dead discards from commercial fisheries; catch for bluefin tuna includes commercial landings and discards and recreational landings; and swordfish include commercial landings and discards. International catch and landings tables are included for the pelagic longline and purse seine fisheries in Sections 3.4.1 and 3.4.2 of this document. At this point, data necessary to assess the U.S. regional and total percentage of international catch levels for Atlantic shark species are unavailable.

**Table 3.21 Calendar Year 2004 U.S. vs International Catch of HMS (mt ww) other than sharks.** Source: SCRS, 2005.

| | | | | | | **U.S. Percentage of Total Atlantic Catch** |
|---|---|---|---|---|---|---|
| Atlantic Swordfish | 25,173* (includes N. & S. Atlantic) | North Atlantic | 12,283* | 2,600 | 21.17% | 10.39% |
| | | South Atlantic | 12,779* | 16 | 0.13% | |
| Atlantic Bluefin Tuna | 28,889** | West Atlantic | 1,928 | 971 | 50.36% | 3.36% |
| Atlantic Bigeye Tuna | 72,349 | Total Atlantic | 72,349 | 414 | 0.57% | 0.57% |
| Atlantic Yellowfin Tuna | 116,275 | West Atlantic | 29,829 | 6,500 | 21.79% | 5.59% |
| Atlantic Albacore Tuna | 52,775 (includes N. & S. Atlantic and Mediterranean) | North Atlantic | 25,460 | 646 | 2.54% | 1.23% |
| | | South Atlantic | 22,468 | 1 | 0.004% | |
| Atlantic Skipjack Tuna | 161,089 | West Atlantic | 26,910 | 102 | 0.38% | 0.06% |
| Atlantic Blue Marlin | 2,076 | North Atlantic | 596 | 59*** | 9.90% | 2.84% |
| Atlantic White Marlin | 532 | North Atlantic | 190 | 28*** | 14.74% | 5.26% |
| Atlantic Sailfish | 2,167 | West Atlantic | 1,017 | 40 | 3.93% | 1.85% |

* Actual catches are likely higher given significant non-compliance with ICCAT reporting requirements.
** Significant non-compliance with ICCAT reporting requirements affects SCRS from estimating aggregate 2004 eastern Atlantic bluefin tuna catches accurately.
***The U.S. catch of marlins reported in the DEIS was lower as discards were inadvertently omitted.

### 3.4.1 Pelagic Longline Fishery

#### 3.4.1.1 Domestic History and Current Management

The U.S. pelagic longline fishery for Atlantic HMS primarily targets swordfish, yellowfin tuna, and bigeye tuna in various areas and seasons. Secondary target species include dolphin, albacore tuna, pelagic sharks (including mako, thresher, and porbeagle sharks), as well as several species of large coastal sharks. Although this gear can be modified (*e.g.*, depth of set, hook type, etc.) to target swordfish, tunas, or sharks, it is generally a multi-species fishery. These vessel operators are opportunistic, switching gear style and making subtle changes to target the best available economic opportunity of each individual trip. Pelagic longline gear sometimes attracts and hooks non-target finfish with little or no commercial value, as well as species that cannot be retained by commercial fishermen due to regulations, such as billfish. Pelagic longlines may also interact with protected species such as marine mammals, sea turtles, and seabirds. Thus, this gear has been classified as a Category I fishery with respect to the Marine Mammal Protection Act. Any species (or undersized catch of permitted species) that cannot be landed due to fishery regulations is required to be released, whether dead or alive. Pelagic longline gear is composed of several parts (see Figure 3.25[2]) (NMFS, 1999).

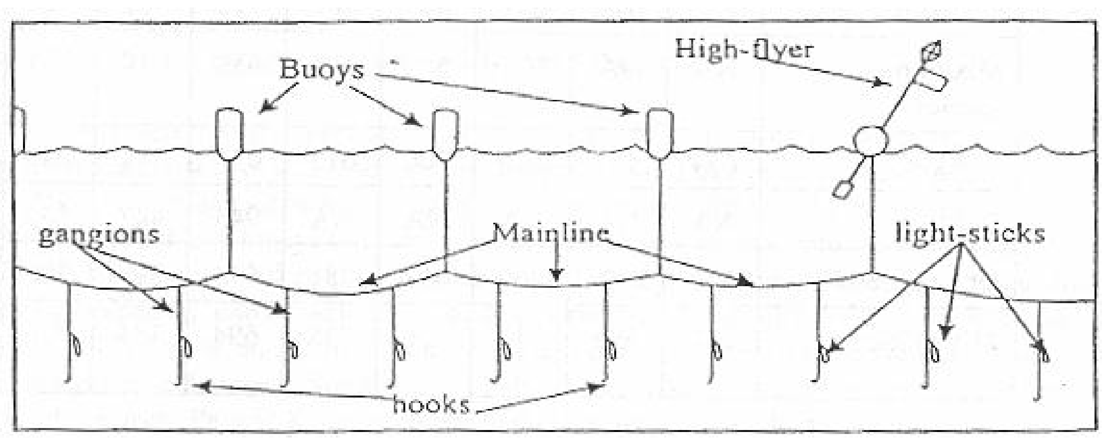

**Figure 3.25 Typical U.S. Pelagic Longline Gear.** Source: Arocha, 1996

The primary fishing line, or mainline of the longline system, can vary from five to 40 miles in length, with approximately 20 to 30 hooks per mile. The depth of the mainline is determined by ocean currents and the length of the floatline, which connects the mainline to several buoys, and periodic markers which can have radar reflectors or radio beacons attached. Each individual hook is connected by a leader, or gangion, to the mainline. Lightsticks, which contain chemicals that emit a glowing light, are often used, particularly when targeting swordfish. When attached to the hook and suspended at a certain depth, lightsticks attract baitfish, which may, in turn, attract pelagic predators (NMFS, 1999).

[2] As of April 1, 2001, (66 FR 17370) a vessel is considered to have pelagic longline gear on board when a power-operated longline hauler, a mainline, floats capable of supporting the mainline, and leaders (gangions) with hooks are on board.

When targeting swordfish, pelagic longline gear is generally deployed at sunset and hauled at sunrise to take advantage of swordfish nocturnal near-surface feeding habits (NMFS, 1999). In general, longlines targeting tunas are set in the morning, deeper in the water column, and hauled in the evening. Except for vessels of the distant water fleet, which undertake extended trips, fishing vessels preferentially target swordfish during periods when the moon is full to take advantage of increased densities of pelagic species near the surface. The number of hooks per set varies with line configuration and target species (Table 3.22) (NMFS, 1999). The pelagic longline gear components may also be deployed as a trolling gear to target surface feeding tunas. Under this configuration, the mainline and gangions are elevated and actively trolled so that the baits fish on or above the water's surface. This style of fishing is often referred to as "green-stick fishing," and reports indicate that it can be extremely efficient compared to conventional fishing techniques. For more information on green-stick fishing gear and the configurations allowed under current regulations, please refer to the discussions of alternative H4 in Chapters 2 and 4 of this document.

**Table 3.22 Average Number of Hooks per Pelagic Longline Set, 1999-2004.** Source: Data reported in pelagic longline logbook.

| | | | | | | **2004** |
|---|---|---|---|---|---|---|
| Swordfish | 521 | 550 | 625 | 695 | 712 | 701 |
| Bigeye Tuna | 768 | 454 | 671 | 755 | 967 | 400 |
| Yellowfin Tuna | 741 | 772 | 731 | 715 | 723 | 696 |
| Mix of tuna species | NA | 638 | 719 | 767 | 764 | 779 |
| Shark | 613 | 621 | 571 | 640 | 970 | 1,046 |
| Dolphin | NA | 943 | 447 | 542 | 692 | 1,033 |
| Other species | 781 | 504 | 318 | 300 | 865 | 270 |
| Mix of species | 738 | 694 | 754 | 756 | 750 | 777 |

Figure 3.26 illustrates basic differences between swordfish (shallow) sets and tuna (deep) longline sets. Swordfish sets are buoyed to the surface, have few hooks between floats, and are relatively shallow. This same type of gear arrangement is used for mixed target sets. Tuna sets use a different type of float placed much further apart. Compared with swordfish sets, tuna sets have more hooks between the floats and the hooks are set much deeper in the water column. It is believed that because of the difference in fishing depth, tuna sets hook fewer turtles than the swordfish sets. In addition, tuna sets use bait only, while swordfish fishing uses a combination of bait and lightsticks. Compared with vessels targeting swordfish or mixed species, vessels specifically targeting tuna are typically smaller and fish different grounds.

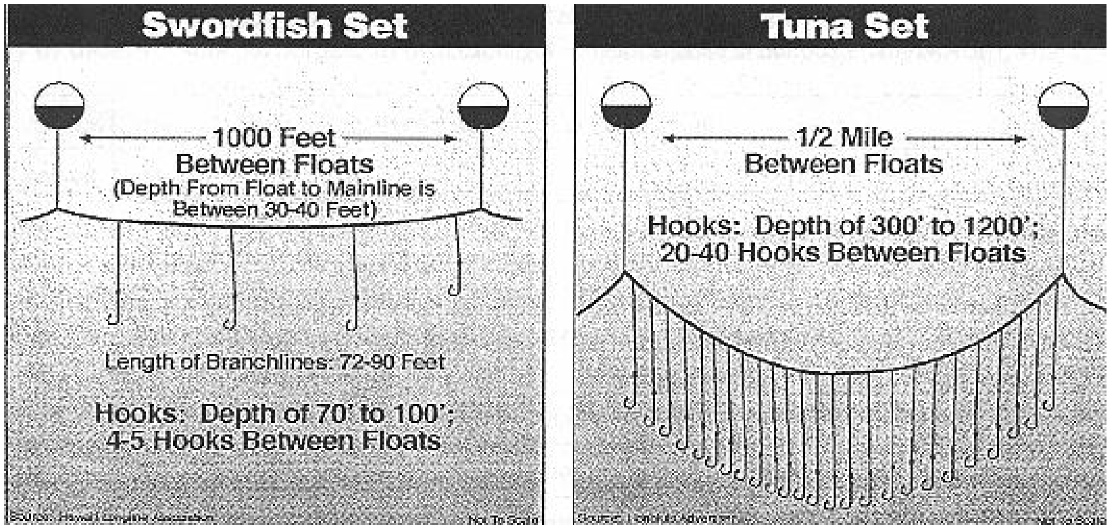

**Figure 3.26 Different Pelagic Longline Gear Deployment Techniques.** Source: Hawaii Longline Association and Honolulu Advertiser.

NOTE: This figure is only included to show basic differences in pelagic longline gear configuration and to illustrate that this gear may be altered to target different species.

*Regional U.S. Pelagic Longline Fisheries Description*

The U.S. pelagic longline fishery sector has historically been comprised of five relatively distinct segments with different fishing practices and strategies, including the Gulf of Mexico yellowfin tuna fishery, the South Atlantic-Florida east coast to Cape Hatteras swordfish fishery, the Mid-Atlantic and New England swordfish and bigeye tuna fishery, the U.S. distant water swordfish fishery, and the Caribbean Islands tuna and swordfish fishery. Each vessel type has different range capabilities due to fuel capacity, hold capacity, size, and construction. In addition to geographical area, these segments have historically differed by percentage of various target and non-target species, gear characteristics, and deployment techniques. Some vessels fish in more than one fishery segment during the course of the year (NMFS, 1999). Due to the many changes in the regulations since 1999 (*e.g.*, time/area closures and gear restrictions), the fishing practices and strategies of these different segments may have changed.

The Gulf of Mexico Yellowfin Tuna Fishery

Gulf of Mexico vessels primarily target yellowfin tuna year-round; however, each port has one to three vessels that directly target swordfish, either seasonally or year-round. Longline fishing vessels that target yellowfin tuna in the Gulf of Mexico also catch and sell dolphin, swordfish, other tunas, and sharks. During yellowfin tuna fishing, few swordfish are captured incidentally. Many of these vessels participate in other Gulf of Mexico fisheries (targeting shrimp, shark, and snapper/grouper) during allowed seasons. Home ports for this fishery include Madiera Beach, Florida; Panama City, Florida; Dulac, Louisiana; and Venice, Louisiana (NMFS, 1999).

For catching tuna, the longline gear is configured similar to swordfish longline gear but is deployed differently. The gear is typically set out at dawn (between two a.m. and noon) and retrieved at sunset (4 p.m. to midnight). The water temperature varies based on the location of fishing. However, yellowfin tuna are targeted in the western Gulf of Mexico during the summer when water temperatures are high. In the past, fishermen have used live bait, however, NMFS prohibited the use of live bait in an effort to decrease bycatch and bycatch mortality of billfish (65 FR 47214, August 1, 2000). This rule also closed the Desoto Canyon area (year-round closure) to pelagic longline gear. In the Gulf of Mexico, and all other areas, except the NED, specific circle hooks (16/0 or larger non-offset and 18/0 or larger with an offset not to exceed 10 degrees) are currently required, as are whole finfish and squid baits.

<u>The South Atlantic – Florida East Coast to Cape Hatteras Swordfish Fishery</u>

Historically, South Atlantic pelagic longline vessels targeted swordfish year-round, although yellowfin tuna and dolphin fish were other important marketable components of the catch. In 2001 (65 FR 47214, August 1, 2000), the Florida East Coast closed area (year-round closure) and the Charleston Bump closed area (February through April closure) became effective. NMFS analyzed logbook data to determine the effectiveness of these closed areas (Sections 2.1.2 and 4.1.2).

Prior to these closures, smaller vessels used to fish short trips from the Florida Straits north to the bend in the Gulf Stream off Charleston, South Carolina (Charleston Bump). Mid-sized and larger vessels migrate seasonally on longer trips from the Yucatan Peninsula throughout the West Indies and Caribbean Sea, and some trips range as far north as the Mid-Atlantic coast of the United States to target bigeye tuna and swordfish during the late summer and fall. Fishing trips in this fishery average nine sets over 12 days. Home ports (including seasonal ports) for this fishery include Georgetown, South Carolina; Charleston, South Carolina; Fort Pierce, Florida; Pompano Beach, Florida; and Key West, Florida. This sector of the fishery consists of small to mid-size vessels, which typically sell fresh swordfish to local high-quality markets (NMFS, 1999).

<u>The Mid-Atlantic and New England Swordfish and Bigeye Tuna Fishery</u>

Fishing in this area has evolved during recent years to focus almost year-round on directed tuna trips, with substantial numbers of swordfish trips as well. Some vessels participate in directed bigeye/yellowfin tuna fishing during the summer and fall months and then switch to bottom longline and/or shark fishing during the winter when the large coastal shark season is open. In 1999, NMFS closed the Northeastern U.S. area in June to pelagic longline gear to reduce bluefin tuna discards (64 FR 29090, May 28, 1999). Fishing trips in this fishery sector average 12 sets over 18 days. During the season, vessels primarily offload in the ports of New Bedford, Massachusetts; Barnegat Light, New Jersey; Ocean City, Maryland; and Wanchese, North Carolina (NMFS, 1999).

<u>The U.S. Atlantic Distant Water Swordfish Fishery</u>

This fishing ground covers virtually the entire span of the western north Atlantic to as far east as the Azores and the Mid-Atlantic Ridge. Approximately 12 large fishing vessels that fish in the distant water operate out of Mid-Atlantic and New England ports during the summer and fall months targeting swordfish and tunas, and then move to Caribbean ports during the winter and spring months. Many of the current distant water operations were among the early participants in the U.S. directed Atlantic commercial swordfish fishery. These larger vessels, with greater ranges and capacities than the coastal fishing vessels, enabled the United States to become a significant participant in the north Atlantic fishery. They also fish for swordfish in the south Atlantic. The distant water vessels traditionally have been larger than their southeast counterparts because of the distances required traveling to the fishing grounds. Fishing trips in this fishery tend to be longer than in other fisheries, averaging 30 days and 16 sets. Ports for this fishery range from San Juan, Puerto Rico through Portland, Maine, and include New Bedford, Massachusetts, and Barnegat Light, New Jersey (NMFS, 1999). This segment of the fleet was directly affected by the L-shaped closure in 2000 and the NED closure implemented in 2001. A number of vessels have recently returned to this fishery with the issuance of the July 6, 2004, rule (69 FR 40734) to reduce sea turtle bycatch and bycatch mortality. Unlike in other areas, vessels fishing in the NED are required to use 18/0 or larger circle hooks with an offset not to exceed 10 degrees and whole mackerel or squid baits.

The Caribbean Tuna and Swordfish Fishery

This fleet is similar to the southeast coastal fishing fleet in that both are comprised primarily of smaller vessels that make short trips relatively near-shore, producing high quality fresh product. Both fleets also encounter relatively high numbers of undersized swordfish at certain times of the year. Longline vessels targeting HMS in the Caribbean use fewer hooks per set, on average, fishing deeper in the water column than the distant water fleet off New England, the northeast coastal fleet, and the Gulf of Mexico yellowfin tuna fleet. This fishery is typical of most pelagic fisheries, being truly a multi-species fishery, with swordfish as a substantial portion of the total catch. Yellowfin tuna, dolphin and, to a lesser extent, bigeye tuna, are other important components of the landed catch. Ports for this fishery include St. Croix, U.S. Virgin Islands; and San Juan, Puerto Rico. Many of these high quality fresh fish are sold to local markets to support the tourist trade in the Caribbean (NMFS, 1999).

*Management of the U.S. Pelagic Longline Fishery*

The U.S. Atlantic pelagic longline fishery is restricted by a limited swordfish quota, divided between the North and South Atlantic (separated at 5°N. Lat.). Other regulations include minimum sizes for swordfish, yellowfin, bigeye, and bluefin tuna, limited access permitting, bluefin tuna catch requirements, shark quotas, protected species incidental take limits, reporting requirements (including logbooks), and gear and bait requirements. Current billfish regulations prohibit the retention of billfish by pelagic longline vessels, or the sale of billfish from the Atlantic Ocean. As a result, all billfish hooked on pelagic longlines must be discarded, and are considered bycatch. This is a heavily managed gear type and, as such, is strictly monitored. Because it is difficult for pelagic longline fishermen to avoid undersized fish in some areas, NMFS has closed areas in the Gulf of Mexico and along the east coast. The intent of these closures is to decrease bycatch in the pelagic longline fishery by closing those areas with the highest rates of bycatch. There are also time/area closures for pelagic longline fishermen designed to reduce the incidental catch of bluefin tuna and sea turtles. In order to enforce time/area closures and to monitor the fishery, NMFS requires all pelagic longline vessels to report positions on an approved vessel monitoring system (VMS).

In June 2004, NMFS conditionally re-opened the NED to pelagic longline fishing. NMFS limited vessels with pelagic longline gear onboard in that area, at all times, to possessing onboard and/or using only 18/0 or larger circle hooks with an offset not to exceed ten degrees. Only whole mackerel and squid baits may be possessed and or utilized with allowable hooks. In August of 2004, NMFS limited vessels with pelagic longline gear onboard, at all times, in all areas open to pelagic longline fishing, excluding the NED, to possessing onboard and/or using only 16/0 or larger non-offset circle hooks and/or 18/0 or larger circle hooks with an offset not to exceed ten degrees. Only whole finfish and squid baits may be possessed and/or utilized with allowable hooks. All pelagic longline vessels must possess and use sea turtle handling and release gear in compliance with NMFS careful release protocols.

Permits

The 1999 FMP established six different limited access permit types: (1) directed swordfish, (2) incidental swordfish, (3) swordfish handgear, (4) directed shark, (5) incidental shark, and (6) tuna longline. To reduce bycatch in the pelagic longline fishery, these permits were designed so that the swordfish directed and incidental permits are valid only if the permit holder also holds both a tuna longline and a shark permit. Similarly, the tuna longline permit is valid only if the permit holder also holds both a swordfish (directed or incidental, not handgear) and a shark permit. This allows limited retention of species that might otherwise have been discarded.

As of February 1, 2006, approximately 214 tuna longline limited access permits had been issued. In addition, approximately 191 directed swordfish limited access permits, 86 incidental swordfish limited access permits, 240 directed shark limited access permits, and 312 incidental shark limited access permits had been issued. Vessels with limited access swordfish and shark permits do not necessarily use pelagic longline gear, but these are the only permits that allow for the use of pelagic longline gear in HMS fisheries.

Monitoring and Reporting

Pelagic longline fishermen and the dealers who purchase HMS from them are subject to reporting requirements. NMFS has extended dealer reporting requirements to all swordfish importers as well as dealers who buy domestic swordfish from the Atlantic. These data are used to evaluate the impacts of harvesting on the stock and the impacts of regulations on affected entities.

Commercial HMS fisheries are monitored through a combination of vessel logbooks, dealer reports, port sampling, cooperative agreements with states, and scientific observer coverage. Logbooks contain information on fishing vessel activity, including dates of trips, number of sets, area fished, number of fish, and other marine species caught, released, and retained. In some cases, social and economic data such as volume and cost of fishing inputs are also required.

Pelagic Longline Observer Program

During 2005, NMFS observers recorded 796 pelagic longline sets for an overall fishery coverage of 10.1 percent. In non-experimental fishing, the overall observer coverage was 7.2 percent. A total of 247 experimental pelagic longline sets were observed in the NEC, GOM, FEC, MAB, and SAB areas, primarily during the second and third quarters. These experimental sets (EXP) had 100 percent observer coverage and are separated from the normal commercial fishery in Table 3.23 (Walsh and Garrison, 2006). In 2004, NMFS observers recorded 702 pelagic longline sets for an overall coverage of 7.3 percent. During the first and second quarters of 2004, 60 experimental sets employing circle hooks were made in the Gulf of Mexico (EXP). These sets had 100 percent observer coverage (Garrison, 2005). One thousand eighty-eight pelagic longline sets were observed and recorded by NMFS observers in 2003 (11.5 percent overall coverage – 100 percent coverage in the NED; and 6.2 percent coverage in remaining areas) (Garrison and Richards, 2004). Table 3.23 details the amount of observer coverage in past years for this fleet. Generally, due to logistical problems, it has not always been possible to place observers on all selected trips. NMFS is working towards improving compliance with observer requirements and facilitating communication between vessel operators and observer program coordinators. In addition, fishermen are reminded of the safety requirements for the placement of observers specified at 50 CFR 600.746, and the need to have all safety equipment on board required by the U.S. Coast Guard.

**Table 3.23 Observer Coverage of the Pelagic Longline Fishery.** Source: Yeung, 2001; Garrison, 2003; Garrison and Richards, 2004; Garrison, 2005; Walsh and Garrison, 2006.

| | | | | Percentage of Total Number of Sets | | |

*In 2001, 2002, and 2003, 100 percent observer coverage was required in the NED research experiment.
** In 2004 and 2005 there was 100 percent observer coverage in experimental fishing (EXP).

### 3.4.1.2 Recent Catch and Landings

U.S. pelagic longline catch (including bycatch, incidental catch, and target catch) is largely related to these vessel and gear characteristics, but is summarized for the whole fishery in Table 3.24. U.S. pelagic longline landings of Atlantic tunas and swordfish for 1999 – 2004 are summarized in Table 3.25. Additional information related to landings can be seen in Section 3.4.6

From May 1992 through December 2000, the Pelagic Observer Program (POP) recorded a total of 4,612 elasmobranchs (15 percent of the total catch) caught off the southeastern U.S. coast in fisheries targeting tunas and swordfish (Beerkircher *et al.*, 2004). Of the 22 elasmobranch species observed, silky sharks were numerically dominant (31.4 percent of the elasmobranch catch), with silky, dusky, night, blue, tiger, scalloped hammerhead, and unidentified sharks making up the majority (84.6 percent) (Beerkircher *et al.*, 2004).

### *Marine Mammals*

Of the marine mammals that are hooked by U.S. pelagic longline fishermen, many are released alive, although some animals suffer serious injuries and may die after being released. The observed and estimated marine mammal interactions for 1992 – 2005 are summarized in Table 3.26 and Table 3.27. Marine mammals are caught primarily during the third and fourth quarters in the Mid-Atlantic Bight (MAB) and Northeast Coastal (NEC) areas (Figure 3.27). In 2005, the majority of observed interactions were with pilot whales in the MAB area (Walsh and Garrison, 2006).

In 2000, there were 14 observed takes of marine mammals by pelagic longlines. This number has been extrapolated based on reported fishing effort to an estimated 403 mammals fleet-wide (32 common dolphin, 93 Risso's dolphin, 231 pilot whales, 19 whales, 29 pygmy sperm whales) (Yeung, 2001). In 2001 and 2002, there were 16 and 24 observed takes of marine mammals, respectively. The majority of these interactions were observed in the MAB, followed by the NED research experiment. In 2001, there were an estimated total of 84 Risso's dolphin and 93 pilot whale interactions in the pelagic longline fishery. In 2002, there were an estimated 87 Risso's dolphin and 114 pilot whale interactions in the pelagic longline fishery. In the NED research experiment, an additional four Risso's dolphin and one northern bottlenose whale were recorded with serious injuries during 2001, as well as three Risso's dolphin, one unidentified dolphin, and one unidentified marine mammal in 2002. One striped dolphin was recorded as released alive during the NED experiment in 2001, as well as one Risso's dolphin, one common dolphin, one pilot whale, and one unidentified dolphin in 2002 (Garrison, 2003).

In 2003, there were 28 observed takes of marine mammals in the pelagic longline fishery. The majority of these interactions were observed in the MAB, followed by the NED experimental fishery, and the NEC area. This number has been extrapolated based on reported fishing effort to an estimated 300 mammals fleet wide (49 beaked whales, 16 dolphin, 30 Atlantic spotted dolphin, 46 common dolphin, 105 Risso's dolphin, 32 pilot whales, 22 minke whales). In addition, five Risso's dolphin, one striped dolphin, and one baleen whale were observed captured in the 2003 NED research experiment, with one Risso's dolphin recorded as dead (Garrison and Richards, 2004).

There were a total of 12 observed interactions with marine mammals in the pelagic longline fishery in 2004. The majority of these interactions was with pilot whales and was observed in the MAB area. During 2004, the pelagic longline fishery was estimated to have interacted with 108 pilot whales, 49 Risso's dolphins, and seven common dolphins (Garrison, 2005). In 2005, there were a total of 24 observed interactions with marine mammals in the pelagic longline fishery. The majority of these interactions was with pilot whales and was observed in the MAB area. During 2005, the pelagic longline fishery was estimated to have interacted with 294 pilot whales, 42 Risso's dolphin, six common dolphin, five bottlenose dolphin, four Atlantic spotted dolphin, one beaked whale, 13 unidentified marine mammals, three unidentified whales, and three unidentified dolphin (Walsh and Garrison, 2006). NMFS monitors observed interactions with sea turtles and marine mammals on a quarterly basis and reviews data for appropriate action, if any, as necessary. In June 2005, NMFS convened the Pelagic Longline Take Reduction Team (PLTRT) to assess and reduce marine mammal takes, specifically pilot whales and Risso's dolphins, by the pelagic longline fishery. At the time of writing, the Pelagic Longline Take Reduction Plan (PLTRP) was expected to be finalized soon.

*Sea Turtles*

Currently, many sea turtles are taken in the GOM and NEC areas (Figure 3.27) and most are released alive. In the past, the bycatch rate was highest in the third and fourth quarters. Loggerhead and leatherback turtles dominate the catch of sea turtles. In general, sea turtle captures are rare, but takes appear to be clustered (Hoey and Moore, 1999).

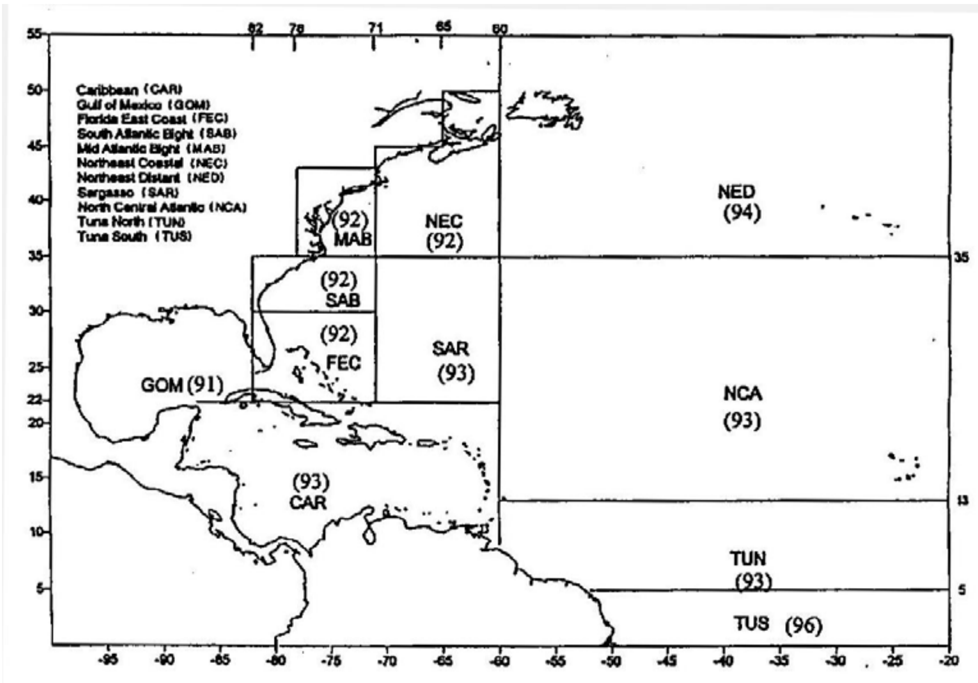

**Figure 3.27 Geographic Areas Used in Summaries of Pelagic Logbook Data.** Source: Cramer and Adams, 2000

The estimated take levels for 2000 were 1,256 loggerhead and 769 leatherback sea turtles (Yeung, 2001). The estimated sea turtle takes for regular fishing and experimental fishing effort for 2001 - 2005 are summarized in Table 3.28. The majority of leatherback interactions have occurred in the Gulf of Mexico. Loggerhead interactions are more widely distributed, however, the NEC, FEC, and Gulf of Mexico appear to be areas with high interaction levels each year.

In 2005, the pelagic longline fishery interacted with an estimated 351 leatherback sea turtles and 275 loggerhead sea turtles outside of experimental fishing operations. During 2005, the interactions with leatherback sea turtles were highest in the Gulf of Mexico (179 animals). The majority of loggerhead sea turtle interactions occurred in the NEC, MAB, CAR, SAR, and SAB areas (Walsh and Garrison, 2006). NMFS monitors observed interactions with sea turtles and marine mammals on a quarterly basis and reviews data for appropriate action, if any, as necessary.

As a result of the increased sea turtle interactions in 2001 and 2002, NMFS reinitiated consultation for the pelagic longline fishery and completed a new BiOp on June 1, 2004. The June 2004 BiOp concluded that long-term continued operation of the Atlantic pelagic longline fishery is not likely to jeopardize the continued existence of loggerhead, green, hawksbill, Kemp's ridley, or olive ridley sea turtles, but is likely to jeopardize the continued existence of leatherback sea turtles. The BiOp included a reasonable and prudent alternative (RPA) and an incidental take statement (ITS) for the combined years 2004 – 2006, and for each subsequent three-year period (NMFS, 2004b).

A final rule published in July 2004 (69 FR 40734) prohibited the possession of "J"-style hooks in the pelagic longline fishery and required the possession and use of specific sea turtle release and disentanglement gears, handling and release protocols, as well as requiring the use of specific circle hooks and baits.

<u>NED Research Experiment</u>

Consistent with the conservation recommendation of an earlier, 2001 BiOp, NMFS initiated a research experiment in the NED area in consultation and cooperation with the domestic pelagic longline fleet. The goal was to develop and evaluate the efficacy of new technologies and changes in fishing practices to reduce sea turtle interactions. In 2001, the experiment attempted to evaluate the effect of gangions placed two gangion lengths from floatlines, the effect of blue-dyed bait on target catch and sea turtle interactions, and the effectiveness of dipnets, line clippers, and dehooking devices. Eight vessels participated, making 186 sets, between August and November. During the course of the research experiment, 142 loggerhead and 77 leatherback sea turtles were incidentally captured and no turtles were released dead.

The data gathered during the 2001 experiment were analyzed to determine if the tested measures reduced the incidental capture of sea turtles by a statistically significant amount. The blue-dyed bait parameter decreased the catch of loggerheads by 9.5 percent and increased the catch of leatherbacks by 45 percent. Neither value is statistically significant. In examining the gangion placement provision, the treatment sections of the gear (with gangions placed 20 fathoms from floatlines) did not result in a statistically significant reduction in the number of loggerhead and leatherback sea turtle interactions than the control sections of the gear (with a gangion located under a floatline). The treatment section of the gear recorded an insignificant increase in the number of leatherback interactions. Following an examination of the data, NMFS discovered that the measures had no significant effect upon the catch of sea turtles (Watson *et al.*, 2003).

Dipnets and line clippers were examined for general effectiveness. The dipnets were found to be adequate in boating loggerhead sea turtles. Several line clippers were tested, with the La Force line clipper having the best performance. Several types of dehooking devices were tested, with the work on these devices continuing in the 2002 and 2003 NED research experiment.

In the summer and fall of 2002, NMFS conducted the second year of the research experiment. The use of circle and "J"-hooks, whole mackerel bait, squid bait, and shortened daylight soak time were tested to examine their effectiveness in reducing the capture of sea turtles. The data indicate there were 501 sets made by 13 vessels with 100 percent observer coverage. During the course of the experiment, 100 loggerhead and 158 leatherback sea turtles were captured and 11 were tagged with satellite tags. In addition to the sea turtles, the vessels interacted with one unidentified marine mammal, one unidentified dolphin, one common dolphin, one longfin pilot whale, and four Risso's dolphins; all were released alive (Watson *et al.*, 2003).

In 2003, the research experiment tested a number of treatments to verify the results of the 2002 experiment in addition to testing additional treatments. Data indicate that there were 539 sets made by 11 vessels with 100 percent observer coverage. During the course of the experiment, one olive ridley, 92 loggerhead, and 79 leatherback sea turtles were captured; all were released alive (Foster *et al.*, 2004; Watson *et al.*, 2004). In addition to the sea turtles, the vessels interacted with one striped dolphin, one baleen whale, and five Risso's dolphin resulting in one mortality (Garrison and Richards, 2004).

From 2001 through 2003, NMFS worked with the commercial fishing industry to develop new pelagic longline fishing technology to reduce interaction rates and bycatch mortality of threatened and endangered sea turtles. The cooperative gear technology research investigated line configurations, setting and retrieving procedures, hook types, hook sizes, bait types, and release and disentanglement gears. Ultimately, specific hook designs and bait types were found to be the most effective measures for reducing sea turtle interactions. Large circle hooks and mackerel baits were found to substantially reduce sea turtle interactions over the use of the industry standard “J”-hooks and squid baits. The gears developed to remove hooks and line from hooked and entangled sea turtles are anticipated to reduce post-hooking mortality associated with those interactions not avoided. Since the conclusion of the NED research experiment, NMFS has continued to investigate pelagic longline bycatch mitigation techniques in the Gulf of Mexico, Atlantic Ocean, and the Caribbean Sea. Additionally, NMFS held a series of voluntary workshops for U.S. pelagic longline fishermen providing outreach and training in sea turtle handling and release techniques.

NMFS believes that the transfer of this information to other fishing countries will result in significant reductions in interaction rates and post-release mortalities of threatened and endangered sea turtles throughout their ranges.

*Seabirds*

Gannets, gulls, greater shearwaters, and storm petrels are occasionally hooked by Atlantic pelagic longlines. These species and all other seabirds are protected under the Migratory Bird Treaty Act. Seabird populations are often slow to recover from excess mortality as a consequence of their low reproductive potential (one egg per year and late sexual maturation). The majority of longline interactions with seabirds occur as the gear is being set. The birds eat the bait and become hooked on the line. The line then sinks and the birds are subsequently drowned.

The United States has developed a National Plan of Action in response to the Food and Agriculture Organization of the United Nations (FAO) International Plan of Action to reduce the incidental takes of seabirds (www.nmfs.gov.gov/NPOA-S.html ). Although Atlantic pelagic longline interactions will be considered in the plan, NMFS has not identified a need to implement gear modifications to reduce seabird takes by Atlantic pelagic longlines. Takes of seabirds have been minimal in the fishery, most likely due to the setting of longlines at night and/or fishing in areas where birds are largely absent.

Observer data from 1992 through 2005 indicate that seabird bycatch is relatively low in the U.S. Atlantic pelagic longline fishery (Table 3.29). Since 1992, a total of 129 seabird interactions have been observed, with 95 observed killed (73.6 percent). In 2005, a total of four seabirds were observed taken.

Observed bycatch has ranged from one to 18 seabirds observed dead per year and zero to 15 seabirds observed released alive per year from 1992 through 2003. Half of the seabirds observed were not identified to species (n = 59). Of the seabirds identified, gulls represent the largest group (n = 35), followed by greater shearwaters (n = 23), and northern gannets (n = 8) (Table 3.30). Greater shearwaters experienced the highest mortality (96.2 percent), followed by gulls (80 percent), and unidentified seabirds (67.8 percent). Northern gannets had the lowest mortality rate (12.5 percent).

Preliminary estimates of expanded seabird bycatch and bycatch rates from 1995 – 2004, varied by year and species with no apparent pattern (Table 3.31). The estimated number of all seabirds caught and discarded dead ranged from zero to 468 per year, while live discards ranged from zero to 292 per year. The annual bycatch rate of birds discarded dead ranged from zero to 0.0486 birds per 1,000 hooks, while live discards ranged from zero to 0.0303 birds per 1,000 hooks.

*Finfish*

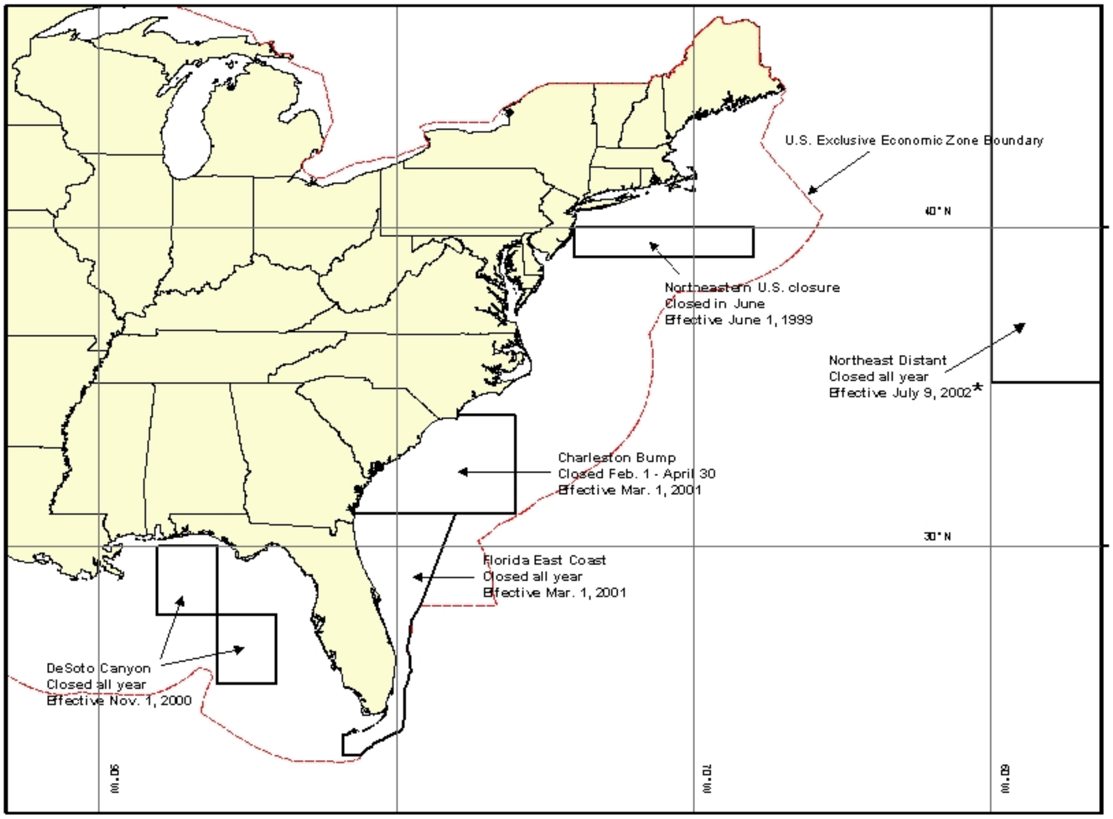
In the U.S. pelagic longline fishery, fish are discarded for a variety reasons. Swordfish, yellowfin tuna, and bigeye tuna may be discarded because they are undersized or unmarketable (*e.g.*, shark bitten). Blue sharks, as well as other species, are discarded because of a limited markets (resulting in low prices) and perishability of the product. Large coastal sharks are discarded during times when the shark season is closed. Bluefin tuna may be discarded because target catch requirements for other species have not been met. Also, all billfish are required to be released. In the past, swordfish have been discarded when the swordfish season was closed. Reported catch from 1999 – 2004 for the U.S. pelagic longline fishery (including reported bycatch, incidental catch, and target catch) is summarized in Table 3.24. Additional U.S. landings and discard data are available in the 2005 U.S. National Report to ICCAT (NMFS, 2005).

At this time, direct use of observer data with pooling for estimating dead discards in this fishery represents the best scientific information available for use in stock assessments. Direct use of observer data has been employed for a number of years to estimate dead discards in Atlantic and Pacific longline fisheries, including billfish, sharks, and undersized swordfish. Furthermore, the data have been used for scientific analyses by both ICCAT and the Inter-American Tropical Tuna Commission (IATTC) for a number of years.

Bycatch mortality of marlins, swordfish, and bluefin tuna from all fishing nations may significantly reduce the ability of these populations to rebuild, and it remains an important management issue. In order to minimize bycatch and bycatch mortality in the domestic pelagic longline fishery, NMFS implemented regulations to close areas to this gear type (Figure 3.28) and has banned the use of live bait by pelagic longline vessels in the Gulf of Mexico.

As part of the bluefin tuna rebuilding program, ICCAT recommends an allowance for dead discards. The U.S. annual dead discard allowance is approximately 68 mt ww. The estimate for the 2004 calendar year was used as a proxy to calculate the amount to be added to, or subtracted from, the U.S. bluefin tuna landings quota for 2005. The 2004 calendar year preliminary estimate of U.S. dead discards, as reported per the longline discards calculated from logbook tallies, adjusted as warranted when observer counts in quarterly/geographic stratum exceeded logbook reports, totaled 72 mt ww. Estimates of dead discards from other gear types and fishing sectors that do not use the pelagic longline vessel logbook are unavailable at this time, and thus, are not included in this calculation. As U.S. fishing activity is estimated to have exceeded the approximate 68 mt ww dead discard allowance by approximately 4.0 mt, the ICCAT recommendation and U.S. regulations state that the United States must account for this excess. Therefore, NMFS shall subtract the amount in excess (approximately 4.0 mt) from the amount of bluefin tuna that can be landed in the subsequent fishing year by those categories accounting for the dead discards.

The 2005 calendar year preliminary dead discard estimate is not yet available. The 2004 calendar year preliminary dead discard estimate, as reported in pelagic longline vessel logbooks and published in 2005 Final Initial Quota Specifications (70 FR 33033, June 7, 2005), totaled 71.8 mt ww. This preliminary estimate has been revised using the longline discards calculated from logbook tallies, adjusted as warranted when observer counts in stratum exceeded logbook reports. The revised 2004 calendar year dead discard estimate is 72.0 mt ww.



* Closed except to vessels complying with specific conditions (see 50 CFR 635 for details).

**Figure 3.28 Areas Closed to Pelagic Longline Fishing by U.S. Flagged Vessels**

### 3.4.1.3 Safety Issues

Like all offshore fisheries, pelagic longlining can be dangerous. Trips are often long, the work is arduous, and the nature of setting and hauling longline gear may result in injury or death. Like all other HMS fisheries, longline fishermen are exposed to unpredictable weather. NMFS does not wish to exacerbate unsafe conditions through the implementation of regulations. Therefore, NMFS considers safety factors when implementing management measures in the pelagic longline fishery. For example, all time/area closures are expected to be closed to fishing, not transiting, in order to allow fishermen to make a direct route to and from fishing grounds. NMFS seeks comments from fishermen on any safety concerns they may have. Fishermen have pointed out that, due to decreasing profit margins, they may fish with less crew or less experienced crew or may not have the time or money to complete necessary maintenance tasks. NMFS encourages fishermen to be responsible in fishing and maintenance activities.

#### 3.4.1.4 International Issues and Catch

Pelagic longline fisheries for Atlantic HMS primarily target swordfish and tunas. Directed pelagic longline fisheries in the Atlantic have been operated by Spain, the United States, and Canada since the late 1950s or early 1960s. The Japanese pelagic longline tuna fishery started in 1956 and has operated throughout the Atlantic since then (NMFS, 1999). Most of the 35 other ICCAT nations now also operate pelagic longline vessels.

ICCAT generally establishes management recommendations on a species (*e.g.*, swordfish) or issue basis (*e.g.*, data collection) rather than by gear type. For example, ICCAT typically establishes quotas or landing limits by species, not gear type. In terms of data collection, ICCAT may require use of specific collection protocols or specific observer coverage levels in certain fisheries or on vessels of a certain size, but these are usually applicable to all gears, and not specific to any one gear type. However, there are a handful of management recommendations that are specifically applicable to the international pelagic longline fishery. These include, a prohibition on longlining in the Mediterranean Sea in June and July by vessels over 24 meters in length, a prohibition on pelagic longline fishing for bluefin tuna in the Gulf of Mexico, and mandated reductions in Atlantic white and blue marlin landings for pelagic longline and purse seine vessels from specified levels, among others.

Because most ICCAT management recommendations pertain to individual species or issues, as discussed above, it is often difficult to obtain information specific to the international pelagic longline fishery. For example, a discussion of authorized total allowable catches (TAC) for specific species in this section of the document would be of limited utility because it is not possible to identify what percentage of quotas are allocated to pelagic longline. Division of quota, by gear type, is typically done by individual countries.

Nevertheless, ICCAT does report landings by gear type. Available data indicate that longline effort produces the second highest volume of catch and effort, and is the most broadly distributed (longitudinally and latitudinally) of the gears used to target ICCAT managed species (Figure 3.29) (SCRS, 2004). Purse seines produce the highest volume of catch of ICCAT managed species from the Atlantic (SCRS, 2004). From 1999 through 2002 (inclusive) there was a declining trend in estimated international landings of HMS for fisheries in which the United States participated. In 2004, international landings of HMS for fisheries in which the U.S. participated totaled 106,774 mt, which represented a modest decrease from 2003 (SCRS, 2005). Detailed information on international Atlantic pelagic longline catches can be found in

Table 3.33.

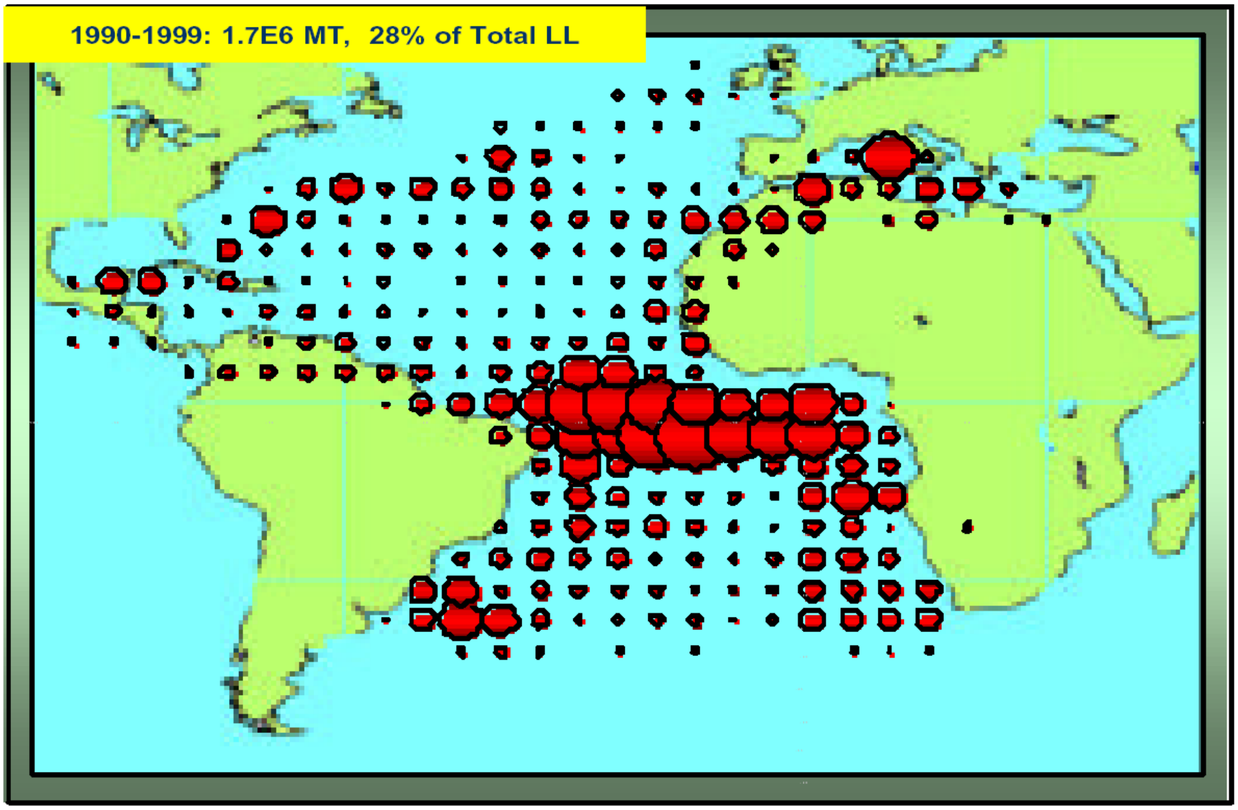


**Figure 3.29 Distribution of Atlantic Longline Catches for all Countries 1990-1999.** Source: SCRS, 2004

Scientific observer data are being collected on a range of pelagic longline fleets in the Atlantic and will be increasingly useful in better quantifying total catch, catch composition, and disposition of catch as these observer programs mature. Previous ICCAT observer coverage requirements of five percent for non-purse seine vessels that participated in the bigeye and yellowfin tuna fishery, including pelagic longline (per ICCAT Recommendation 96-01), are no longer in force. There is currently no ICCAT required minimum level of observer coverage specific to pelagic longline fishing. Nevertheless, the United States has implemented a mandatory observer program in the U.S. pelagic longline fishery. Japan is required to have eight percent observer coverage of its vessels fishing for swordfish in the North Atlantic, which are primarily pelagic longline vessels, however, the recommendation is not specific to vessel or gear type. ICCAT recommendation 04-01, a conservation and management recommendation for the bigeye tuna fishery, entered into force in mid-2005 and requires at least five percent observer coverage of pelagic longline vessels over 24 meters fishing for bigeye.

ICCAT has also developed a running tabulation of the diversity of species caught by the various gears used to target tunas and tuna like species in the Atlantic and Mediterranean (Table 3.32). For all fish species, longline gear shows the highest documented diversity of catch, followed by gillnets and purse seine. For seabirds, longline gear again shows the highest diversity of catch, while for sea turtles and marine mammals, purse seine and gillnet have a higher documented diversity of species for Atlantic tuna fleets (SCRS, 2004).

*U.S. Pelagic Longline Catch in Relation to International Catch*

Highly Migratory Species

The U.S. pelagic longline fleet represents a small fraction of the international pelagic longline fleet that competes on the high seas for catches of tunas and swordfish. In recent years, the proportion of U.S. pelagic longline landings of HMS, for the fisheries in which the United States participates, has remained relatively stable in proportion to international landings (Table 3.33). The U.S. fleet accounts for less than 0.5 percent of the landings of swordfish and tuna from the Atlantic Ocean south of 5°N. latitude, and does not operate at all in the Mediterranean Sea. Tuna and swordfish landings by foreign fleets operating in the tropical Atlantic and Mediterranean are greater than the catches from the north Atlantic area where the U.S. fleet operates. Even within the area where the U.S. fleet operates, the U.S. portion of fishing effort (in numbers of hooks fished) is less than 10 percent of the entire international fleet's effort, and likely less than that due to differences in reporting effort between ICCAT countries (NMFS, 2001).

[4]Includes U.S. *dead discards.*
[5]Includes swordfish, blue marlin, white marlin, and sailfish longline discards.

### *Atlantic Sharks*

There is currently no comprehensive international reporting system for Atlantic shark catches and landings. While there are some international data, not all countries report shark catches and landings and those that do use varying reporting methods. The most recent landings reports for blue and shortfin mako sharks are presented in Table 3.34 and Table 3.35, respectively. In 2001, ICCAT passed a resolution on Atlantic sharks to determine needed improvements in data collection for Atlantic shortfin mako and blue sharks, and to conduct an interim meeting in 2003 to discuss the issue. In addition, the resolution called upon contracting parties and non-contracting parties to: (1) submit catch and effort data on Atlantic shortfin mako, porbeagle, and blue sharks; (2) encourage the release of live sharks that are caught incidentally; (3) minimize waste and discards from shark catches; and (4) voluntarily agree not to increase fishing effort targeting Atlantic porbeagle, shortfin mako and blue sharks until sustainable levels of harvest can be determined through stock assessments.

At its annual meeting in New Orleans in 2004, ICCAT adopted a recommendation to, among other things, ban shark finning, require vessels to fully utilize their entire catches of sharks, encourage the release of live sharks that are caught incidentally and are not used for food, and review the assessment of shortfin mako sharks in 2005, and reassess blue sharks and shortfin mako no later than 2007. The ICCAT recommendation also encouraged countries to engage in research to identify shark nursery areas, and collect data on shark catches.

Sea Turtles

From 1999 to 2003, the U.S. pelagic longline fleet targeting HMS captured an average of 772 loggerhead and 1,013 leatherback sea turtles per year, based on observed takes and total reported effort. In 2004, the U.S. pelagic longline fleet was estimated to have captured 734 loggerhead and 1,359 leatherback sea turtles (Garrison, 2005). In 2005, the U.S. pelagic longline fishery was estimated to have interacted with 274 loggerhead and 351 leatherback sea turtles outside of experimental fishing operations (Walsh and Garrison, 2006). Since other ICCAT nations do not monitor incidental catches of sea turtles, an exact assessment of their impact is not possible. However, high absolute numbers of sea turtle catches in the foreign fleets have been reported from other sources (NMFS, 2001). Throughout the Atlantic basin, including the Mediterranean Sea, a total of 210,000 – 280,000 loggerhead and 30,250 – 70,000 leatherback sea turtles are estimated to be captured by pelagic longline fisheries each year (Lewiston *et al.*, 2004).

Mortality in the domestic and foreign pelagic longline fisheries is just one of numerous factors affecting sea turtle populations in the Atlantic (National Research Council, 1990). Many sources of anthropogenic mortality are outside of U.S. jurisdiction and control. If the U.S. swordfish quota was relinquished to other fishing nations, the effort now expended by the U.S. fleet would likely be replaced by foreign effort. This could significantly alter the U.S. position at ICCAT and make the implementation of international conservation efforts more difficult. This would also eliminate the option of gear or other experimentation with the U.S. longline fleet, thus making it difficult to find take reduction solutions which could be transferred to other longlining nations to effect a greater global reduction in sea turtle takes in pelagic longline fisheries. The United States has, and will continue to make efforts at ICCAT, Inter-American Tropical Tuna Commission (IATTC), and other international forums, to encourage adoption of sea turtle conservation measures by international fishing fleets.

The first international agreement devoted solely to the protection of sea turtles – the Inter-American Convention for the Protection and Conservation of Sea Turtles – was concluded on September 5, 1996, in Salvador, Brazil, and entered into force in May 2001. The Inter-American Convention called for the Parties to establish national sea turtle conservation programs. In addition to domestic rulemaking in various fisheries, NMFS has been active at the international level in promoting sea turtle conservation efforts. A summery of some of these efforts is provided below.

In February 2003, the United States supported a workshop consisting of technical experts on sea turtle biology and longline fishery operations from interested nations in order to share information and discuss possible solutions to reduce incidental capture of marine turtles in these fisheries. The United States introduced the NED sea turtle bycatch mitigation research at the November 2003, ICCAT meeting in Dublin, Ireland, and co-sponsored ICCAT Resolution 03-11 which encouraged other nations to improve data collection and reporting on sea turtle bycatch and promote the safe handling and release of incidentally captured sea turtles. A poster and video describing the NED research experiment and preliminary results were displayed, as well as many of the experimentally tested release gears.

In January 2004, the Northeast Distant Waters Longline Research ad hoc advisory group met in Miami, Florida. The purpose of this meeting was to present a summary of the 2001 and 2002 NED pelagic longline sea turtle bycatch mitigation research and the preliminary results for the 2003 research, and to discuss future research needs. Also in January 2004, the IATTC - CIAT Bycatch Working Group met in Kobe, Japan. The purpose of U.S. attendance at this meeting was to present results of sea turtle mitigation research by the U.S, to hear research results on bycatch mitigation from other countries, to encourage IATTC countries to evaluate or adopt sea turtle mitigation technology in their fisheries, and to address other bycatch issues in longline fisheries. A Workshop was held in conjunction with the Sea Turtle Symposium in San Jose, Costa Rica in February 2004. The focus of this workshop was on providing information on the safe release of sea turtles to participants from nations with longline fleets. In June 2004, NMFS SEFSC staff conducted longline mitigation training and workshops in Peru, in cooperation with the IATTC. In August 2004, a workshop was held in Panama on conducting circle hook experiments similar to those undertaken in Ecuador (see description below) and on the use of dehooking devices and safe handling and release techniques. Also in August 2004, a workshop was held in Guatemala on conducting circle hook experiments similar to Ecuador and on the use of dehooking devices, safe handling and release techniques. In October 2004, Southwest Fisheries Science Center (SWFSC) staff followed up on a training workshop held in 2003 in cooperation with the Instituo del Mar del Peru (IMARPE) for fisheries observers, by working with Peruvian researchers to initiate circle hook implementation and experiments in the artisanal dolphin and shark fisheries.

At the Annual ICCAT meeting in New Orleans in November 2004, NMFS staff conducted a workshop discussing experimental results and the use of circle hooks, the use of dehooking devices, and safe handling and release techniques. Also in November, a workshop was conducted at the meeting of the Gulf and Caribbean Fisheries Institute in Saint Petersburg, Florida.

In collaboration with the World Wildlife Fund (WWF), IATTC, and the Western Pacific Regional Fishery Management Council (WPRFMC), NMFS provided hooks, dehooking devices, and technical assistance to Ecuador for the testing of non-offset 14/0 and 15/0 circle hooks in the dolphin fishery and 10 degree offset 16/0 and 18/0 circle hooks in the tuna/shark fisheries. Work began in March 2004 and initial results indicate that the majority of the bycatch is entangled, not hooked. Pacific Islands Fisheries Science Center (PIFSC) staff has been consulting with WPRFMC, Blue Ocean Institute, and Japan on a cooperative research design to test the efficiency of circle hooks in the Japanese tuna fishery. A draft research plan was reviewed in May 2004, and a meeting to refine the draft was held in Honolulu in Sept 2004. In June 2004, NMFS staff gave a presentation promoting cooperative research and the use of circle hooks at a Symposium on Bycatch Reduction hosted by the National Fisheries Research and Development Institute (NFRDI) in Korea.

The first Technical Assistance Workshop on Sea Turtle Bycatch Reduction Experiments in Longline Fisheries was held in April 2005, in Honolulu. This workshop was held to provide technical assistance for participants from the FAO Technical Consultation to design programs for the development and testing of turtle bycatch reducing technology appropriate to the longline fisheries of participating nations. The Third International Fishers Forum was held in Yokahama, Japan in July 2005, and United States' and regional research results on sea turtle bycatch avoidance methods were presented. In 2005, the United States assisted in designing experiments to evaluate sea turtle mitigation techniques and provided technical assistance for the following countries: Australia; Brazil; Costa Rica; Ecuador; Iceland; Italy; Japan; Korea; Taiwan; Mexico; Peru; Philippines; Spain; Uraquay; and, Vietnam.

### 3.4.2 Purse Seine

#### 3.4.2.1 Domestic History and Current Management

Purse seine gear consists of a floated and weighted encircling net that is closed by means of a drawstring; know as a purseline, threaded through rings attached to the bottom of the net. The efficiency of this gear can be enhanced by the assistance of spotter planes used to locate schools of tuna. Once a school is spotted, the vessel, with the aid of a smaller skiff, intercepts and uses the large net to encircle it. Once encircled, the purseline is pulled, closing the bottom of the net and preventing escape. The net is hauled back onboard using a powerblock, and the tunas are removed and placed onboard the larger vessel. Economic and social aspects of the fisheries are described in Sections 3.5 and Chapter 9.0 of this document, respectively.

Vessels using purse seine nets have participated in the U.S. Atlantic tuna fishery continuously since the 1950s; although a number of purse seine vessels did target and land BFT off the coast of Gloucester, MA as early as the 1930s. In 1958, continued commercial purse seining effort for Atlantic tunas began with a single vessel in Cape Cod Bay and expanded rapidly into the region between Cape Hatteras and Cape Cod during the early 1960s. The purse seine fishery between Cape Hatteras and Cape Cod was directed mainly at small and medium BFT, YFT, and at skipjack tuna, primarily for the canning industry. North of Cape Cod, purse seining was directed at giant BFT. High catches of juvenile BFT were sustained throughout the 1960s and into the early 1970s. These high catch rates by U.S. purse seine vessels are believed to have played a role in the decline in abundance during subsequent years. Currently these purse seine vessels focus their effort on giant BFT, versus other tunas, due to the international market that developed for giant BFT in the late 1970s. These fresh caught BFT are primarily flown directly to Japan for processing into sushi or sashimi. By the late 1980s, high ex-vessel prices and the increased importance of the Japanese market had increased effort on all size classes of BFT. In 1992, NMFS responded by banning the sale of school, large school, and small medium BFT (27 inches to less than 73 inches curved fork length).

A limited entry system with non-transferable individual vessel quotas (IVQs) for purse seining was established in 1982, effectively excluding any new entrants into this category. Equal baseline quotas of BFT are assigned to individual vessels by regulation; the IVQ system is possible given the small pool of ownership in this sector of the fishery. Currently, only five vessels comprise the Atlantic tuna purse seine fleet and in 1996 the quotas were made transferable among the five vessels.

Vessels that are participating in the Atlantic tunas purse seine fishery are required to target the larger size class BFT, more specifically the giant sized class (81 inches or larger) and are granted a tolerance limit of 15 percent by weight, of the total amount of giant BFT landed during a season. These vessels may commence fishing starting on July 15 of each year and may continue through December 31, provided the vessel has not fully attained its IVQ. Over the last few years, the Purse seine category has not fully harvested its allocated quota. This can be attributed to a number of different reasons outside of the industry's or NMFS' control, such as lack of availability or schools being comprised of mixed size classes. NMFS has issued several EFPs to this sector of the fishery and will continue to assess current regulations and their impact on providing reasonable opportunities to harvest available quota.

#### 3.4.2.2 Recent Catch and Landings

Table 3.36 shows purse seine landings of Atlantic tunas from 1999 through 2004. Purse seine landings typically make up approximately 20 percent of the total annual U.S. landings of BFT (about 25 percent of total commercial landings), but account for only a small percentage, if any, of the landings of other HMS. In the 1980s and early 1990s, purse seine landings of YFT were often over several hundred metric tons. Over 4,000 mt ww of YFT were recorded landed in 1985. In recent years, via informal agreements with other sectors of the tuna industry, the purse seine fleet has opted not to direct any effort on HMS other than BFT.

**Table 3.36 Domestic Atlantic Tuna Landings for the Purse Seine Fishery: 1999-2004 (mt ww). Northwest Atlantic Fishing Area. Source**: U.S. National Report to ICCAT: 2005.

| | | | | | | **2004** |
|---|---|---|---|---|---|---|
| Bluefin Tuna | 247.9 | 275.2 | 195.9 | 207.7 | 265.4 | 31.8 |
| Yellowfin Tuna | 0 | 0 | 0 | 0 | 0 | 0 |
| Skipjack Tuna | 0 | 0 | 0 | 0 | 0 | 0 |

#### 3.4.2.3 Safety Issues

Accidents that can occur on purse seine vessels include general injuries caused by handling fish (e.g., poisoning from being stuck by fin spines), as well as accidents related to the vessels fishing operations themselves, such as, deploying the skiff or using cables and winches to move giant BFT from the net to the hold.

#### 3.4.2.4 International Issues and Catch

The U.S. purse seine fleet has historically accounted for a small percentage of the total International Atlantic tuna landings. Over the past six years, the U.S. purse seine fishery has contributed to less than 0.15 percent of the total purse seine landings reported to ICCAT.

**Table 3.37 Estimated International Purse Seine Atlantic Tuna Landings in the Atlantic and Mediterranean: 1999-2004 (mt ww).** Source: SCRS, 2005

| | | | | | | **2004** |
|---|---|---|---|---|---|---|
| **Bluefin Tuna** | 15,884 | 17,616 | 17,520 | 18,548 | 15,525 | 122,309 |
| **Yellowfin Tuna** | 83,445 | 80,253 | 102,641 | 95,613 | 80,111 | 61,849 |
| **Skipjack Tuna** | 95,367 | 80,762 | 77,995 | 70,714 | 92,770 | 89,317 |
| **Bigeye Tuna** | 20,923 | 17,909 | 22,060 | 16,192 | 22,237 | 13,388 |
| **Albacore** | 238 | 244 | 288 | 158 | 998 | 674 |
| **Total** | **215,857** | **196,784** | **220,504** | **201,225** | **211,641** | **177,537** |
| **U.S. Total** | **248** | **275** | **196** | **208** | **265** | **32** |
| **U.S. Percentage** | **0.12%** | **0.14%** | **0.09%** | **0.10%** | **0.13%** | **0.02%** |

Since the 1999 ICCAT meeting, ICCAT has continued to implement a Fish Aggregation Device (FAD) closed area in the Gulf of Guinea. The closure (which became mandatory in mid-1999) was in response to concern over catches of juvenile and undersize tunas by non-U.S. internationally flagged purse seiners relying on FADs. The full evaluation of this program is somewhat hindered by the multi-species nature of surface fisheries and the existence of other types of fisheries. The updated analysis indicated that this regulation appeared effective at reducing mortality for juvenile bigeye. Full compliance with this regulation by all surface fisheries will greatly increase the effectiveness of this regulation.

### 3.4.3 Commercial Handgear

#### 3.4.3.1 Domestic History and Current Management

Commercial handgears, including handline, harpoon, rod and reel, and bandit gear are often used to fish for Atlantic HMS by fishermen on private vessels, charter vessels, and headboat vessels. Rod and reel gear may be deployed from a vessel that is at anchor, drifting, or underway (*i.e.*, trolling). In general, trolling consists of dragging baits or lures through, on top of, or even above the water's surface. While trolling, vessels often use outriggers, kites, or green-sticks to assist in spreading out or elevating baits or lures and to prevent fishing lines from tangling. For more information on green-stick fishing gear, and the configurations allowed under current regulations, please refer to the discussions of alternative H4 in Chapters 2 and 4 of this document. Operations, frequency and duration of trips, and distance ventured offshore vary widely. Most of the vessels are greater than seven meters in length and are privately owned by individual fishermen.

The handgear fisheries are typically most active during the summer and fall, although in the South Atlantic and Gulf of Mexico fishing occurs during the winter months. Fishing usually takes place between eight and 200 km from shore and for those vessels using bait, the baitfish typically includes herring, mackerel, whiting, mullet, menhaden, ballyhoo, butterfish, and squid. The commercial handgear fishery for BFT occurs mainly in New England, and more recently off the coast of southern Atlantic states, such as Virginia, North Carolina and South Carolina, with vessels targeting large medium and giant BFT. The majority of U.S. commercial handgear fishing activities for bigeye, albacore, yellowfin, and skipjack tunas take place in the northwest Atlantic. Beyond these general patterns, the availability of Atlantic tunas at a specific location and time is highly dependent on environmental variables that fluctuate from year to year.

Currently the U.S. Atlantic tuna commercial handgear fisheries are managed through an open access vessel permit program. Vessels that wish to sell their Atlantic tunas must obtain a commercial handgear permit in one of the following categories: General (rod and reel, harpoon, handline, bandit gear), Harpoon (harpoon only), or Charter/Headboat (rod and reel and handline). These vessels may also need permits from the states they operate out of in order to land and sell their catch. All commercial permit holders are encouraged to check with their local state fish/natural resource management office regarding these requirements. Permitted vessels are also required to sell their Atlantic tunas to federally permitted Atlantic tuna dealers. As the Atlantic tunas dealer permits are issued by the Northeast Region Permit Office, vessel owner/operators are encouraged to contact the permitting office directly, either by phone at (978) 281-9438 or via the web at http://www.nero.noaa.gov/ro/doc/vesdata1.htm, to obtain a list of permitted dealers in their area.

Vessels that are permitted in the General and Charter/Headboat categories commercially fish under the General category rules and regulations. For instance, regarding BFT, vessels that possess either of the two permits mentioned above have the ability to retain a daily bag limit of zero to three BFT, measuring 73 inches or greater curved fork length per vessel per day while the General category BFT fishery is open. The General category BFT fishery opens on June 1 of each year and remains open until January 31 of the subsequent year, or until the quota is filled. Vessel owner/operators should check with the agency via websites (www.hmspermits.gov) or telephone information lines (1-888-872-8862) to verify the BFT retention limit on any given day. The General category BFT quota is approximately 47 percent of the U.S. quota and equates to a base line allocation of approximately 690 mt.

Vessels that are permitted in the Harpoon category fish under the Harpoon category rules and regulations. For instance, regarding BFT, vessels have the ability to keep two bluefin measuring 73 inches to less than 81 inches curved fork length per vessel trip per day while the fishery is open. There is no limit on the number of BFT that measure longer than 81 inches curved fork length, as long as the Harpoon category season is open. The Harpoon category season also opens on June 1 of each year and remains open until November 15, or until the quota is filled. The Harpoon category BFT quota is approximately 3.9 percent of the U.S. quota and equates to a base line allocation of approximately 57 mt.

U.S. commercial swordfish fishing in the Atlantic Ocean is reported to have begun in the early 1800s as a harpoon fishery off the coast of New England. This fishery traditionally consisted of harpoon vessels operating out of Rhode Island and Massachusetts where they took extended trips for swordfish north and east of the Hudson Canyon and particularly off Georges Bank, and could land as many as 20 to 25 large swordfish over a ten-day period. These fish primarily consisted of large fish that finned on the surface and were available to the harpoon gear, some weighing as much as 600 lbs dw, but averaging about 225 to 300 lbs dw at the turn of the century. Because of the limited effort directed towards large fish, the stock was sufficient to support a sustainable seasonal swordfish fishery for more than 150 years. Most swordfish caught in the United States in the early 1900s were harvested with harpoons; harpoon landings declined from the 1940s through the 1960s. Due to a decreased availability of the large swordfish in the northeast this fishery has essentially ceased to exist. However, a recently emerging swordfish handgear fishery, both commercial and recreational, has appeared to develop off the east coast of Florida. This fishery is essentially prosecuted at night with rod and reel or handline gear. Some vessels participating in this fishery are currently utilizing individual handlines attached to free-floating buoys. This fishery has been operating under the current regulations, which require that handlines be restricted to no more than two hooks and be released and retrieved by hand. The current regulations do not limit the number of individual handlines/buoys that may be possessed or deployed.

Currently the U.S. commercial swordfish fishery is managed through limited access vessel permits. Vessels that possess a limited access handgear permit must abide by the minimum size limits for swordfish (*i.e.,* 29 inches form cleithrum to caudal keel; 47 inches lower jaw fork length; or 33 lbs dressed weight) and seasonal retention limits. When the directed swordfish fishery is open, permitted handgear vessel do not have a possession limit. However, during a directed fishery closure, permitted handgear vessels may land two swordfish per trip, provided these two fish were not taken with harpoon gear. Fishermen with a commercial handgear swordfish permit are required to report fishing activities in an approved logbook within 48 hours of each day's fishing activities for multi-day trips, or before offloading for one-day trips, and submit the logbook within seven days of offloading.

The shark commercial handgear fishery plays a very minor role in contributing to the overall shark landing statistics. For further information regarding the shark fishery refer to Section 3.4.5. Economic and social aspects of all the domestic handgear fisheries are described later in this document (Section 3.5 and Chapter 9.0 respectively).

#### 3.4.3.2 Recent Catch and Landings

The proportion of domestic HMS landings harvested with handgear varies by species, with Atlantic tunas comprising the majority of commercial landings. Commercial handgear landings of all Atlantic HMS (other than sharks) in the United States are shown in Table 3.38.

In 2004, BFT commercial handgear landings accounted for approximately 42 percent of the total U.S. BFT landings, and almost 75 percent of commercial BFT landings.

Also in 2004, four percent of the total yellowfin catch, or nine percent of the commercial yellowfin catch, was attributable to commercial handgear. Commercial handgear landings of skipjack tuna accounted for approximately ten percent of total skipjack landings, or about 30 percent of commercial skipjack landings. For albacore, commercial handgear landings accounted for approximately one percent of total albacore landings, or about six percent of commercial albacore landings. Commercial handgear landings of bigeye tuna accounted for approximately one percent of total bigeye landings and one percent of total commercial bigeye landings.

Updated tables of landings for the commercial handgear fisheries by gear and by area for 1999 – 2004 are presented in the following tables.

**Table 3.38 Domestic Landings for the Commercial Handgear Fishery, by Species and Gear, for 1999-2004 (mt ww).** Source: U.S. National Report to ICCAT: 2005

*Handgear Trip Estimates*

Table 3.40 displays the estimated number of rod and reel and handline trips targeting large pelagic species in 2001 through 2004. The trips include commercial and recreational trips, and are not specific to any particular species. It should be noted that these estimates are still preliminary and subject to change.

### 3.4.3.3 Safety Issues Associated with the Fishery

The U.S. Coast Guard (USCG) conducts routine vessel safety inspections at sea on a variety of vessels throughout the year. During the busy General category BFT season the USCG has been known to concentrate patrol activities on General category BFT boats. Boarding officers indicate that the majority of the commercial handgear vessels have the necessary safety equipment; however, many part-time fishermen operating smaller vessels do not meet the necessary safety standards. There have been several cases of vessels participating in the commercial handgear fishery that have capsized due to weight while attempting to boat commercial-sized BFT (measuring 73 inches or greater and weighing several hundred pounds).

Over the last few years, the USCG focused boardings on small vessels, especially those owned by "part-time" commercial handgear fishermen, and terminated several dozen trips due to the lack of safety equipment on board. If a vessel is boarded at sea and found to be lacking major survival equipment, the USCG will terminate the trip and escort the vessels back to port.

Currently, NMFS does not require proof of proper safety equipment as a condition to obtain a commercial handgear permit. Instead, NMFS informs permit applicants that commercial vessels are subject to the Fishing Vessel Safety Act of 1988 and advises them to contact their local USCG office for further information. The USCG District Boston office reports receiving 50 to 75 calls a week during the peak fishing season; officers speak with all callers to answer vessel questions. Since NMFS regulations do not require USCG inspection or safety equipment in order to obtain a commercial handgear permit, NMFS cannot be certain that all participants in the commercial handgear fisheries are adequately prepared for the conditions they may encounter. NMFS is concerned about the safety of all vessels participating in the commercial handgear fisheries and continues to work with the USCG to improve communication of vessel safety requirements to commercial handgear vessel operators.

It is unlawful for Atlantic tuna vessels to engage in fishing unless the vessel travels to and from the area where it will be fishing under its own power and the person operating that vessel brings any BFT under control (secured to the catching vessel or on board) with no assistance from another vessel, except when shown by the operator that the safety of the vessel or its crew was jeopardized or other circumstances existed that were beyond the control of the operator. NMFS Enforcement and USCG boarding officers have recently encountered vessels participating in the BFT fishery that are unable to transit to and from the fishing grounds due to their limited fuel capacity. Occasionally these smaller vessels will work in cooperation with a larger documented vessel to catch a BFT; others have been observed leaving lifesaving equipment at the dock to make room for extra fuel, bait, and staples. NMFS is concerned that use of such inadequately equipped vessels jeopardizes crew in that the vessel may not be able to safely return to shore without assistance of the larger vessel due to insufficient fuel or to adverse weather conditions.

Over the last couple of years, NMFS has received a number of vessel permit applications from kayak owner/operators. In addition to the requirement mentioned above, NMFS only issues permits to vessels that possess a USCG Documentation number, a state registration number, or a foreign registration number (recreational permit only). As kayaks typically do not require such documentation NMFS has denied all applications for a kayak to date.

NMFS also has concerns regarding individuals embarking on HMS trips by themselves. Recently there have been a few incidents of fishermen either severely injuring themselves or dying while pursing HMS by themselves. Certain hazardous situations could be mitigated by having an additional person onboard the vessel while conducting a trip targeting large pelagics. NMFS encourages vessel owner/operators to practice safe fishing techniques.

NMFS will consider all safety comments and information, including those from the USCG and NMFS Enforcement, when planning future General category effort control schedules and will discuss these issues in future meetings with the AP.

#### 3.4.3.4 U.S. vs. International Issues and Catch

SCRS data do not lend themselves to organize international landings into a commercial handgear category. While some countries report rod and reel landings, these numbers may include both commercial and recreational landings. International catches of all Atlantic HMS for 2004 are summarized in Table 3.21.

### 3.4.4 Recreational Handgear

The following section describes the recreational portion of the handgear fishery, and is primarily focused upon rod and reel fishing. The HMS Handgear (rod and reel, handline, and harpoon) fishery includes both commercial and recreational fisheries and is described fully in Section 2.5.8 of the 1999 FMP. Handgear components may also be deployed as a specialized trolling gear to target surface-feeding tunas. Under this configuration, the line and leaders are elevated and actively trolled so that the baits fish on or above the water's surface. This style of fishing is often referred to as "green-stick fishing," and reports indicate that it can be extremely efficient compared to conventional fishing techniques. For more information on green-stick fishing gear and the configurations allowed under current regulations, please refer to the discussions of alternative H4 in Chapters 2 and 4 of this document. The recreational billfish fishery is described fully in Section 2.1.3 of the 1999 Billfish Amendment. The commercial sale, barter or trade of Atlantic billfish by U.S. commercial interests is prohibited, only recreational landings are authorized.

#### 3.4.4.1 Overview of History and Current Management

Atlantic tunas, swordfish, and sharks are managed under the 1999 FMP and Amendment 1 to the 1999 FMP, while Atlantic billfish are managed separately under the Billfish FMP, as amended. Summaries of the domestic aspects of the Atlantic tuna fishery, the Atlantic swordfish fishery, and the Atlantic shark fishery are found in Sections 2.2.3, 2.3.3, and 2.4.3, respectively, of the 1999 FMP. A history of Atlantic billfish management is provided in Section 1.1.1 of the Billfish Amendment and Section 3.1.2 of this document.

Atlantic tunas, sharks, swordfish, and billfish are all targeted by domestic recreational fishermen using rod and reel gear. The recreational swordfish fishery had declined dramatically over the past twenty years, but recent information indicates that the recreational swordfish fishery is rebuilding in the Mid-Atlantic Bight, and off the east coast of Florida. Effective March 1, 2003, an HMS Angling category permit has been required to fish recreationally for any HMS-managed species (Atlantic tunas, sharks, swordfish, and billfish) (67 FR 77434, December 18, 2002). Prior to March 1, 2003, the regulations only required vessels fishing recreationally for Atlantic tunas to possess an Atlantic Tunas Angling category permit.

Recreational fishing for Atlantic HMS is managed primarily through the use of minimum size limits and bag limits. Recreational tuna fishing regulations are the most complex and include a combination of minimum sizes, bag limits, limited season-based quota allotment for bluefin tuna, and reporting requirements (depending upon the particular species and vessel type).

The recreational swordfish fishery has been managed through the use of a minimum size requirement and landings requirement (swordfish may be headed and gutted but may not be cut into smaller pieces). However, regulations effective March 2003 (68 FR 711) established a recreational retention limit of one swordfish per person up to three per vessel per day. Regardless of the length of a trip, no more than the daily limit of North Atlantic swordfish can be possessed onboard a vessel.

The recreational shark fishery is managed using bag limits, minimum size requirements, and landing requirements (sharks must be landed with head and fins attached). Additionally, the possession of 19 species of sharks is prohibited.

Atlantic blue and white marlin have a combined landings limit (*i.e.*, a maximum of 250 fish that can be landed per year); however, the primary management strategy for the recreational billfish fishery is through the use of minimum size limits. There are no recreational retention limits for Atlantic sailfish, blue marlin, and white marlin. Recreational anglers may not land longbill spearfish.

ICCAT has made several recommendations to recover billfish resources throughout the Atlantic Ocean that are discussed in detail in Section 3.1.2.

#### 3.4.4.2 Most Recent Catch and Landings Data

The recreational landings database for HMS consists of information obtained through surveys including the Marine Recreational Fishery Statistics Survey (MRFSS), Large Pelagic Survey (LPS), Southeast Headboat Survey (HBS), Texas Headboat Survey, and Recreational Billfish Survey Tournament Data (RBS). Descriptions of these surveys, the geographic areas they include, and their limitations, are discussed in Section 2.6.2 of the 1999 FMP and Section 2.3.2 of the 1999 Billfish Amendment.

Reported domestic landings of Atlantic bluefin tuna (1983 through 1998) and BAYS tuna (1995 through 1997) were presented in Section 2.2.3 of the 1999 FMP. As landings figures for 1997 and 1998 were preliminary in the 1999 FMP, updated landings for recreational rod and reel fisheries are presented in Table 3.41 through 2004. Recreational landings of swordfish are monitored by the LPS and the MRFSS. However, because swordfish landings are considered rare events, it is difficult to extrapolate the total recreational landings from dockside intercepts.

An ad hoc committee of NMFS scientists reviewed the methodology and data used to estimate recreational landings of Atlantic HMS during 2004. The Committee was charged with reviewing the 2002 estimates of U.S. recreational landings of bluefin tuna, white marlin and blue marlin reported by NMFS to ICCAT. The committee was also charged with recommending methods to be used for the estimation of 2003 recreational fishery landings of bluefin tuna and marlin. Although the Committee discovered and corrected a few problems with the raw data from the LPS and the estimation program used to produce the estimates, the Committee concluded that the estimation methods for producing the 2002 estimates were consistent with methods used in previous years. The report of the Committee is available at: http://www.nmfs.noaa.gov/sfa/hms/Tuna/2002-2003_Bluefin-Marlin_Report-120304.pdf.

* Rod and reel catches and landings for Atlantic tunas represent estimates of landings and dead discards based on statistical surveys of the U.S. recreational harvesting sector.
** Rod and reel catch and landings estimates of bluefin tuna less than 73" curved fork length (CFL) based on statistical surveys of the U.S. recreational harvesting sector. Rod and reel catch of bluefin > 73" CFL are commercial and may also include a few metric tons of "trophy" bluefin (recreational bluefin 73").
*** Blue and white marlin (1997-2003), and sailfish (1997-2002) landings are based on prior U.S. National Reports to ICCAT and consist primarily of reported tournament landings. Reporting method was changed to a total count (blue and white marlin) in 2004.

*Atlantic Billfish Recreational Fishery*

Due to the rare nature of billfish encounters and the difficulty of monitoring landings outside of tournament events, reports of recreational billfish landings are sparse. However, the RBS provides a preliminary source for analyzing recreational billfish landings. Table 3.42 documents the number of billfish landed in 1999 – 2004, as reported by the RBS.

**Table 3.42 Preliminary RBS Recreational Billfish Landings in numbers of fish (calendar year).** Source: NMFS Recreational Billfish Survey (RBS).

| | | | | | | **2004** |
|---|---|---|---|---|---|---|
| Blue Marlin | 172 | 117 | 75 | 84 | 96 | 110 |
| White Marlin | 36 | 8 | 22 | 33 | 20 | 25 |
| Sailfish | 30 | 18 | 11 | 14 | 24 | 9 |
| Swordfish | - | - | 0 | 16 | 48 | 168 |

In support of the sailfish assessment conducted at the 2001 SCRS billfish species group meeting, document SCRS/01/106 developed indices of abundance of sailfish from the U.S. recreational billfish tournament fishery for the period 1973 – 2000. The index of weight per 100 hours fishing was estimated from numbers of sailfish caught and reported in the logbooks submitted by tournament coordinators and NMFS observers under the RBS, as well as available size information. Document SCRS/01/138 estimated U.S. sailfish catch estimates from various recreational fishery surveys.

All recreational, non-tournament landings of billfish, including swordfish, must be reported within 24 hours of landing to NMFS by the permitted owner of the vessel landing the fish. This requirement is applicable to all permit holders, both private and charter/headboat vessels, not fishing in a tournament. In Maryland and North Carolina, vessel owners should report their billfish landings at state-operated landings stations. A landed fish means a fish that is kept and brought to shore. Due to large-scale non-compliance with the call-in requirement, the landings in Table 3.43 are considered a minimum estimate of the non-tournament landings of billfish.

**Table 3.43 Number of billfish reported to NMFS via call-in system by fishing year, 2002-2005.** Source: G. Fairclough, pers. comm.

| | | | | **2005**** |

* Reporting requirement did not go into effect until March 1, 2003
** 2005 landings as of May 16, 2006

*Swordfish Recreational Fishery*

The recreational swordfish fishery in the North Atlantic Ocean has been steadily expanding in recent years, probably due to increased availability of small swordfish and an increased interest in the sport. Fishermen typically fish off the east coast of Florida and off the coasts of New Jersey and New York. Fish have also occasionally been encountered on trips off Maryland and Virginia. In the past, the New York swordfish fishery occurred incidental to overnight yellowfin tuna trips. During the day, fishermen targeted tunas, while at night they fished deeper for swordfish. This appears to have evolved into a year-round directed fishery off Florida and a summer fishery off of New Jersey. The Florida fishery occurs at night with fishermen targeting swordfish using live or dead bait and additional attractants such as lightsticks, LED lights, and light bars suspended under the boat.

Historically, fishery survey strategies have not captured all landings of recreational handgear-caught swordfish. Although some handgear swordfish fishermen have commercial permits[1], many others land swordfish strictly for personal consumption. Therefore, NMFS published regulations to improve recreational swordfish monitoring and conservation. A trip limit of one swordfish per person, up to three per vessel, and mandatory reporting of all recreationally-landed swordfish and billfish via a toll-free call-in system became effective on March 2, 2003 (68 FR 711). Accordingly, all reported recreational swordfish landings are counted against the incidental swordfish quota.

Recreational fishing tournaments allow for the collection of a large volume of fishery-dependent data in a relatively short time period. Tournaments also provide a "snapshot" of the recreational fishery at a particular time and location. Analysis of tournament data collected over a period of years could provide valuable information regarding trends in the recreational swordfish fishery. A recent study documented recreational handgear-caught swordfish in three south Florida tournaments (J. Levesque, pers. comm.). The tournaments occurred from July though September 2002, two in Lighthouse Point and the other in Ft. Lauderdale. Data was obtained through direct at-sea observation, dockside interviews with anglers landing swordfish, and a telephone interview with a tournament organizer. A total of 156 vessels and between 468 – 624 individuals participated in the three tournaments.

[3] Access to the commercial swordfish fishery is limited; hand gear fishermen however may purchase permits from other permitted fishermen because the permits are transferable.

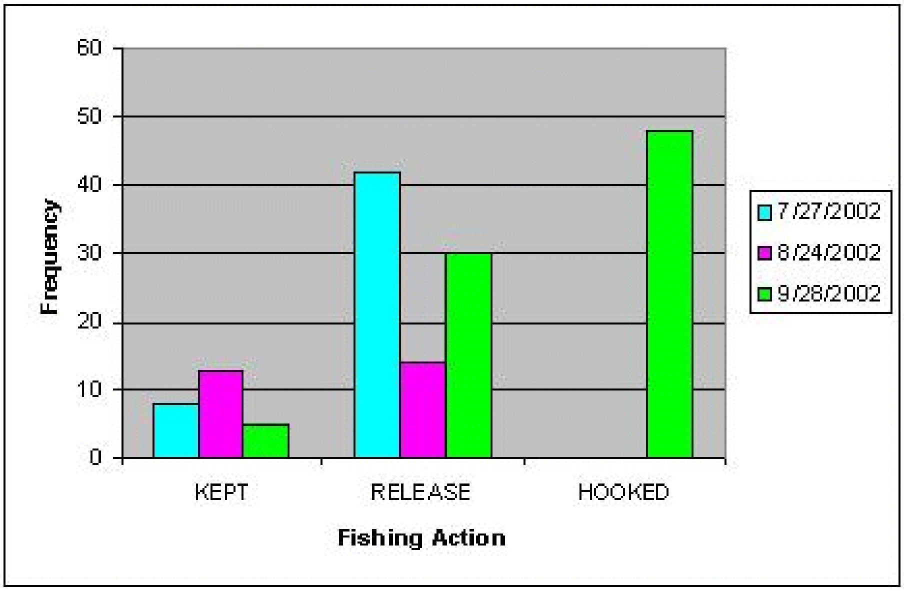

**Figure 3.30 Total Number of Swordfish Caught, Kept and Released in Three Sampled Recreational Swordfish Tournaments off Southeast Florida during 2002.** Source: J. Levesque, pers. comm.

Figure 3.30 indicates that 112 swordfish were caught during the three monitored tournaments. Of these, 26 swordfish were retained and 86 swordfish were released alive. Additional data from the September 28, 2002, tournament indicated that, in that tournament, 48 swordfish were hooked, 30 were released, and four were kept. The definition of hooked, for these purposes, was a swordfish that was on the line for any given amount of time. All hooked fish were assumed to be swordfish. The three fishing tournaments implemented a 55-inch, or 140 cm LJFL minimum size requirement for landed swordfish, although current federal regulations are 119 cm (46.9 in) LJFL.

Sizes for landed swordfish ranged from 130 – 230 cm (51.2 – 90.6 in) fork length. The mean size for landed swordfish was 160 cm (63 in) fork length. Weights for landed swordfish ranged from 36 – 144 kg (79.3 – 317.2 lb). The mean weight for the landed swordfish was 62.6 kg (137.9 lb). Estimated weights for the released swordfish ranged from 13 – 32 kg (28.6 – 70.5 lb). The mean estimated weight for released swordfish was 19.5 kg (43 lb).

The overall number of swordfish hooked per-unit-effort was .0615-swordfish/hr. or 6.15 swordfish per 100-hrs. drifting. The catch per-unit-effort was .0143-swordfish landed/hr. or 1.43 fish per 100-hrs. drifting.

Tournament caught swordfish reported to the RBS have increased in recent years. There were none reported in 2001, 16 in 2002, 48 in 2003, and 168 in 2004. While total tournament landings of swordfish are still low in terms of numbers of fish, it appears that as swordfish have recovered in the past few years, tournament landings of swordfish have increased.

*Shark Recreational Fishery*

Recreational landings of sharks are an important component of HMS fisheries. Recreational shark fishing with rod and reel is a popular sport at all social and economic levels, largely because the resource is accessible. Sharks can be caught virtually anywhere in salt water, depending upon the species. Recreational shark fisheries are oftentimes exploited in nearshore waters by private vessels and charter/headboats. However, there is also some shore-based fishing and some offshore fishing. The following tables provide a summary of landings for each of the three species groups. Amendment 1 to the 1999 Atlantic Tunas, Swordfish, and Shark FMP limited the recreational fishery to rod and reel and handline gear only.

**Table 3.44 Estimates of Total Recreational Harvest of Atlantic Sharks: 1998-2004 (numbers of fish in thousands).** Source: 1998-2000 (Cortés, pers. comm.); 2001-2004 (Cortés, 2005a; 2005b). Estimates for 2001-2004 do not include prohibited species.

### 3.4.4.3 Bycatch Issues and Data Associated with the Fishery

Bycatch in the recreational rod and reel fishery is difficult to quantify because many fishermen value the experience of fishing and may not be targeting a particular pelagic species. Recreational "marlin" or "tuna" trips may yield dolphin, tunas, wahoo, and other species, both undersized and legal sized. Bluefin tuna trips may yield undersized bluefin, or a seasonal closure may prevent landing of a bluefin tuna above a minimum or maximum size. In some cases, therefore, rod and reel catch may be discarded. The Magnuson-Stevens Act (16 USC 1802 (2)) stipulates that bycatch does not include fish under recreational catch-and-release.

The 1999 Billfish Amendment established a catch-and-release fishery management program for the recreational Atlantic billfish fishery. As a result of this program, all Atlantic billfish that are released alive, regardless of size, are not considered bycatch. NMFS believes that establishing a catch-and-release fishery in this situation will further solidify the existing catch-and-release ethic of recreational billfish fishermen, and thereby increase release rates of billfish caught in this fishery. Current billfish release rates range from 89 to 99 percent. The recreational white shark fishery is by regulation a catch-and-release fishery only and white sharks are not considered bycatch.

Bycatch can result in death or injury to discarded fish. Therefore, bycatch mortality should be incorporated into fish stock assessments, and into the evaluation of management measures. Rod and reel discard estimates from Virginia to Maine during June – October could be monitored through the expansion of survey data derived from the LPS (dockside and telephone surveys). However, the actual numbers of fish discarded for many species are so low that presenting the data by area could be misleading, particularly if the estimates are expanded for unreported effort in the future. The number of kept and released fish reported or observed through the LPS dockside intercepts for 1997 – 2004 is presented in Table 3.48.

Outreach programs to address bycatch were included in the 1999 FMP and the Billfish Amendment. These programs have not yet been implemented, but the preparation of program designs is currently in progress. One of the key elements in the outreach program will be to provide information that leads to an improvement in post-release survival from both commercial and recreational gear. Additionally, an outreach program to encourage the use of circle hooks to increase post-release survival within HMS fisheries was introduced in a proposed rule published in 2001 (66 FR 66386, December 26, 2001). The final rule to promote the voluntary use of circle hooks published in 2003 (68 FR 711, January 7, 2003). Initial implementation of the outreach program began in 2004 with workshops conducted on the proper handling and release of sea turtles.

A study by Graves *et al.* (2002), investigated short-term (five days) post-release mortality of Atlantic blue marlin using pop-up satellite tag technology. A total of nine recreationally caught blue marlin were tagged and released during July and August of 1999. All hooks employed in the study were "J" hooks. The attached tags were programmed to detach from the fish after five days and to record direct temperature and inclination of the buoyant tag to determine if the fish were actively swimming after being released. After detachment, the tags floated to the surface and began transmitting recorded position, temperature and inclination data to satellites of the Argos™ system. Three different lines of evidence provided by the tags (movement, water temperature, and tag inclination) suggested that at least eight of the nine blue marlin survived for five days after being tagged and released. One of the tags did not transmit any data, which precluded the derivation of a conclusion regarding the tagged marlin's survival.

This study was continued in 2003 for white marlin to evaluate post release survival and habitat use (NMFS, 2004). Pop-up satellite archival tags (PSATs) were used to estimate survival of white marlin released from four locations in the western North Atlantic recreational fishery. Forty-one tags were attached to white marlin caught using dead baits rigged on straight-shank ("J") hooks (n=21) or circle hooks (n=20) offshore of the U.S. Mid-Atlantic, the Dominican Republic, Mexico, and Venezuela. Survival was significantly higher ($p<0.01$) for white marlin caught on circle hooks (100 percent) relative to those caught on straight-shank ("J") hooks (65 percent). These results, along with previous studies on circle hook performance, suggest that a simple change in hook type can significantly increase the survival of white marlin released from recreational fishing gear. Data from these short term deployments also suggest that white marlin strongly associated with warm, near surface waters. However, based on the frequency, persistence, and patterns of vertical movements, white marlin appear to direct a considerable proportion of foraging effort well below surface waters, a behavior that may account for relatively high catch rates of white marlin on some pelagic longline sets.

[1] NMFS typically expands these "raw" data to report discards of bluefin tuna by the rod and reel fishery to ICCAT. If sample sizes are large enough to make reasonable estimates for other species, NMFS may produce estimates for other species in future SAFE reports.
[2] Amendment One to the Atlantic Billfish FMP established billfish released in the recreational fishery as a "catch-and-release" program, thereby exempting these fish from bycatch considerations.
[3] Includes some commercial handgear landings.

### 3.4.4.4 Safety Issues Associated with the Fishery

The USCG does not maintain statistics on boating accidents, rescue, or casualty data specifically pertaining to recreational fishing as it does for the commercial industry. As a result, the 1999 FMP and the Billfish Amendment contain only minimal safety information regarding recreational HMS fisheries. Safety issues associated with handline fisheries for tunas are discussed in Section 3.4.4.4. The USCG compiles statistics on the total number of recreational boating accidents and casualties, independent of the activity or fishery in which they are engaged (Table 3.49). Two common situations often place recreational boaters in potential danger. Individuals in small vessels often venture out farther than their vessels are designed to travel without proper navigational equipment, and may encounter rougher water than their boats are designed to withstand. Since fishermen targeting HMS species, particularly marlin, often travel 75 to 100 miles offshore, having a properly equipped vessel of adequate size is very important for the safety of recreational HMS constituents. Additionally, as the recreational swordfish fishery off the southeastern coast of Florida occurs at night and usually in small boats ranging from 23 to 40 feet in length, it presents other unique risks. Shipping traffic regularly runs through the recreational swordfish fleet, which could lead to incidents if someone is not on watch at all times. Another frequent safety concern of the Coast Guard is when someone is up in the flying bridge. Both of these situations can lead to people falling overboard. In 2004, approximately 72 percent of all boating casualties were due to drowning and in 89 percent of the drowning deaths, the victim was not wearing a personal floatation device (PFD) (Table 3.50).

### 3.4.4.5 U.S. vs. International Catch

Important directed recreational fisheries for HMS occur in the United States, Venezuela, the Bahamas, and Brazil. Many other countries and entities in the Caribbean and the west coast of Africa are also responsible for significant HMS recreational landings. Directed recreational fisheries for sailfish occur in the Western Atlantic and include the United States, Venezuela, the Bahamas, Brazil, Dominican Republic, Mexico, and other Caribbean nations. However, of these countries, the United States is the only country that currently reports recreational landings to ICCAT. Therefore, a comparison of the percentage of U.S. landings relative to recreational fisheries in other countries is not possible. Further, total landings data are incomplete because many countries that reported landings in 1996 failed to report their 1998 and 1999 landings, which hampered the 2000 Atlantic marlin stock assessments, as well.

As part of a 1997 SCRS survey, 12 ICCAT member countries as well as Chinese Taipei and Senegal provided information on the existence of, and level of data collection for, recreational and artisinal fisheries. The survey results indicated that Brazil, Canada, France, Italy, Morocco, UK, Bermuda, and the United States have recreational fisheries in the ICCAT area of concern. Levels of data collection varied widely from country to country, making any comparison of catch levels difficult and potentially inaccurate. The wide range of recreational catches across nations and species warrants further exploration of potential data sources and the feasibility of increased recreational monitoring.

At the 1999 ICCAT meeting in Rio de Janeiro, Brazil, the Commission adopted a resolution to improve the quantity and quality of recreational data collection. Recreational fisheries were to be discussed and assessed in each country's National Report beginning in the year 2000. In addition, the SCRS was called upon to examine the impact of recreational fishing on tuna and tuna-like species. At this time additional information is not available regarding international HMS recreational catches.

At the 2004 ICCAT meeting in New Orleans, U.S., the Commission adopted a recommendation concerning prohibited gear in the sport and recreational fisheries in the Mediterranean Sea (04-12). Prohibited gear includes towed and encircling nets, seine sliding, dredgers, gill nets, trammel net and longline to fish for tuna and tuna-like species. The recommendation also prohibits the sale of sport and recreational tuna and tuna-like species and stipulates that data on these fisheries be collected and transmitted to the SCRS.

### 3.4.5 Bottom Longline

#### 3.4.5.1 Domestic History and Current Management

In 1993, NMFS implemented the FMP for Sharks of the Atlantic Ocean, which established three management units: large coastal sharks (LCS), small coastal sharks (SCS), and pelagic sharks. At that time, NMFS identified LCS as overfished, and implemented commercial quotas for LCS and established recreational harvest limits for all sharks. In 2003, NMFS amended the measures enacted in the 1999 FMP based on the 2002 LCS and SCS stock assessments, litigation, and public comments. Implementing regulations for Amendment 1 to the 1999 FMP were published on December 24, 2003 (68 FR 74746). Management measures enacted in the amendment included: re-aggregating the large coastal shark complex, using maximum sustainable yield (MSY) as a basis for setting commercial quotas, eliminating the commercial minimum size restrictions, establishing three regional commercial quotas (Gulf of Mexico, South Atlantic, and North Atlantic) for LCS and SCS management units, implementing trimester commercial fishing seasons effective January 1, 2005, imposing gear restrictions to reduce bycatch, and a time/area closure off the coast of North Carolina effective January 1, 2005. As a result of using MSY to establish quotas, and implementing a new rebuilding plan, the overall annual landings quota for LCS in 2004 was established at 1,017 metric tons (mt) dressed weight (dw). The overall annual landings quota for SCS was established at 454 mt dw and the pelagic, blue, and porbeagle shark quotas were established at 488 mt dw, 273 mt dw, and 92 mt dw, respectively.

The regional quotas which were established in Amendment 1 to the 1999 HMS FMP for LCS and SCS were intended to improve overall management of the stocks by tailoring quotas to specific regions based on landings information. These quotas were based upon average historical landings (1999 – 2001) from the canvass and quota monitoring databases. The canvass database provides a near-census of the landings at major dealers in the southeast United States (including state landings) and the quota monitoring database collects information from dealers in the South Atlantic and Gulf of Mexico.

On November 30, 2004, NMFS issued a final rule (69 FR 69537), which established, among other things, new regional quotas based on updated landings information from 1999 –

2003. This final rule did not change the overall quotas for LCS, SCS, and pelagic sharks established in Amendment 1 to the 1999 HMS FMP, but did revise the percentages allocated to each of the regions. The updated information was based on several different databases, including the canvass and quota monitoring databases, the Northeast Commercial Fisheries Database (CFDBS), and the snapper grouper logbook. The new regional quotas and trimester seasons for the commercial Atlantic shark fishery became effective January 1, 2005.

Commercial shark fishing effort is generally concentrated in the southeastern United States and Gulf of Mexico (Cortes and Neer, 2002). During 1997 – 2003, 92 – 98 percent of LCS, 38 – 49 percent of pelagic sharks, and nearly all SCS (80 – 100 percent) came from the southeast region (Cortes, pers. comm.). McHugh and Murray (1997) found in a survey of shark fishery participants that the largest concentration of bottom longline fishing vessels is found along the central Gulf coast of Florida, with the John's Pass - Madeira Beach area considered the center of directed shark fishing activities. Consistent with other HMS fisheries, some shark fishery participants move from their homeports to other fishing areas as the seasons change and fish stocks move.

The Atlantic bottom longline fishery targets both LCS and SCS. Bottom longline is the primary commercial gear employed in the LCS and SCS fisheries in all regions. Gear characteristics vary by region, but in general, an approximately ten-mile long bottom longline, containing about 600 hooks, is fished overnight. Skates, sharks, or various finfishes are used as bait. The gear typically consists of a heavy monofilament mainline with lighter weight monofilament gangions. Some fishermen may occasionally use a flexible 1/16 inch wire rope as gangion material or as a short leader above the hook.

#### 3.4.5.2 Recent Catch and Landings Data

The following section provides information on shark landings as reported in the shark bottom longline observer program. For recent catch and landings data for the shark fishery as a whole, which includes landings from BLL and other gears combined, please refer to Section 3.4.7. In January 2002, the observer coverage requirements in the shark bottom longline fishery changed from voluntary to mandatory participation if selected. NMFS selects approximately 40 - 50 vessels for observer coverage during each season. Vessels are randomly selected if they have a directed shark limited access permit, have reported landings from sharks during the previous year, and have not been selected for observer coverage during each of the three previous seasons.

The U.S. Atlantic commercial shark bottom longline fishery has been monitored by the University of Florida and Florida Museum of Natural History, Commercial Shark Fishery Observer Program (CSFOP) since 1994. In June 2005, responsibility for the observer program was transferred to the Southeast Fisheries Science Center's Panama City Laboratory. The observer program trains and places the observers aboard vessels in the directed shark bottom longline fishery in the Atlantic and Gulf of Mexico to collect data on the commercial shark fishery and thus improve overall management strategies for the fishery. Observers provide baseline characterization information, by region, on catch rates, species composition, catch disposition, relative abundance, and size composition within species for the large coastal and small coastal shark bottom longline fisheries.

During 2003, six observers logged 263 sea days on shark fishing trips aboard 20 vessels in the Atlantic from North Carolina to Florida and in the eastern Gulf of Mexico off Florida. The number of trips taken on each vessel ranged from one to five and the number of sea days each observer logged ranged from nine to 35. Observers documented the catches and fishing effort on approximately 150 longline sets that fished 103,351 hooks. During 2004, five observers logged 196 sea days on 56 shark fishing trips aboard 11 vessels. Observers documented the catches and fishing effort during 120 longline sets that fished 90,980 hooks.

Data from the shark observer program between 2000 and 2002 show that LCS comprised 66.2 percent of the total catch (Burgess and Morgan, 2002). During 2003, LCS comprised 68.4 percent of the total catch, and in 2004 LCS comprised 66.7 percent of the total catch. Sandbar sharks dominated the observed catches with 30.6 percent of total LCS catch in 2003 and 26.6 percent in 2004 (Table 3.52). The overall catch and disposition of species for 2004 is listed in Table 3.53. Regional differences in sandbar shark abundance were evident. For example, in the Carolina region, sandbar sharks comprised 67.4 percent of the total catch and 77.2 percent of the large coastal shark catch. In the Florida Gulf region, sandbar sharks comprised 62.0 percent of the total catch and 66.5 percent of the large coastal catch, whereas in the Florida East Coast region, sandbar sharks comprised only 17.2 percent of the total observed catch, and 37.1 percent of the large coastal shark catch (Burgess and Morgan, 2003). Blacktip sharks comprised 13.9 percent of total observed catch and 20.3 percent of the large coastal catch (Burgess and Morgan, 2002). Tiger sharks comprised 7.5 percent of the total observed catch and 11.0 percent of the large coastal shark catch. A majority of tiger sharks (71.7 percent) and nurse sharks (98.8 percent) were tagged and released.

During 2003, shark observer program data indicate that SCS comprised 28.0 percent of the total observed catch (Burgess and Morgan, 2003; Burgess and Morgan 2004). Atlantic sharpnose shark dominated the SCS catch (80.3 percent). The remainder of the small coastal catch consisted of blacknose sharks (5.5 percent), bonnethead (0.03 percent), and finetooth (0.02 percent)(Table 3.52). In previous seasons, the Atlantic sharpnose shark was the most frequently caught shark in the Florida East Coast region and accounted for 51.6 percent of the total observed catch, and 96.0 percent of the small coastal catch in that region (Burgess and Morgan, 2002).

Bottom longlining for sharks has relatively low observed bycatch rates. Historically, finfish bycatch has averaged approximately five percent in the bottom longline fishery. Finfish bycatch for the bottom longline fishery includes, but is not limited to, skates, rays, cobia, redfish, bluefish, and great barracuda. During the second semi-annual season of 2003, observer data indicate that approximately 4,320 sharks were caught compared to 432 other fish, four invertebrates, and three sea turtles (Burgess and Johns, 1999). In terms of bycatch rates, observed shark catches constitute 91 percent of the 4,759 total animals caught, with other fish comprising 10 percent, invertebrates less than .01 percent, and sea turtles less than .01 percent. For more information on bycatch see Section 3.8.

#### 3.4.5.3 Bottom Longline Bycatch

Under the Marine Mammal Protection Act (MMPA) (16 U.S.C. 1361 et seq.) the Atlantic shark gillnet fishery is classified as Category II (occasional serious injuries and mortalities), and the shark bottom longline as Category III (remote likelihood or no known serious injuries or mortalities) (July 20, 2004, 69 FR 43338). On October 29, 2003, NMFS issued a biological opinion (BiOp) pursuant to the Endangered Species Act (ESA) regarding Atlantic shark fisheries. This BiOp concluded that the level of anticipated take in the Atlantic shark fishery resulting from measures implemented in Amendment 1 to the 1999 FMP (68 FR 74746), were not likely to jeopardize the continued existence of endangered green, leatherback, and Kemp's ridley sea turtles, the endangered smalltooth sawfish, or the threatened loggerhead sea turtle. Furthermore, it concluded that the actions in the rule were not likely to adversely affect marine mammals. As a result of this conclusion, NMFS (NMFS, 2003) anticipates that the continued operation of the shark bottom longline fishery will result in a five year total incidental take of the following numbers of sea turtles: Leatherback – 172; loggerhead – 1,370; a total of 30 in any combination of hawksbill, green, and Kemp's ridley sea turtles. NMFS also anticipates a five year take of 261 smalltooth sawfish, of which no lethal takes are expected. If the actual calculated incidental captures or mortalities exceed the incidental take statement, a formal consultation for that gear type must be re-initiated immediately. More information is available in Amendment 1 to the 1999 FMP and the October 2003 BiOp and is not repeated here.

*Loggerhead Sea Turtles*

In the bottom longline fishery, a total of 65 sea turtles were observed caught from 1994 through 2006 (Table 3.54 Table 3.55 and Figure 3.31). Seasonal variation indicates that most of the sea turtles were caught early in the year. Of the 65 observed sea turtles, 50 were loggerhead sea turtles, of which 26 were released alive. Another nine loggerheads were released in an unknown condition and eight were released dead. Based on extrapolation of observer data in Amendment 1 to the 1999 FMP, it was estimated that a total of 2,003 loggerhead sea turtles were taken in the shark bottom longline fishery from 1994 through 2002 (NMFS, 2003a). An additional 503 unidentified sea turtles were estimated to have been taken. On average, 222 loggerhead sea turtles and 56 unidentified sea turtles were estimated to have been taken annually during this time period in the shark bottom longline fishery.

*Leatherback Sea Turtles*

Of the 65 observed sea turtle interactions in the bottom longline fishery from 1994 – 2006, six were leatherback sea turtles of which one was dead and three were released with their condition unknown (Table 3.54 Table 3.55 and Figure 3.31). Based on extrapolation of observer data done for Amendment 1 to the FMP, it was estimated that 269 leatherback sea turtles were taken in the shark bottom longline fishery from 1994 through 2002 (NMFS, 2003a). On average, 30 leatherback sea turtle interactions occurred each year in the shark bottom longline fishery during this period. This analysis only estimates takes without discriminating between live and dead releases. Of the observed leatherback takes, approximately 25 percent were lethal. Applying the observed mortality rate of 25 percent to the total leatherback takes and an additional 42 percent post-release mortality estimate due to hook ingestion to the remaining, results in an estimated total number of leatherbacks killed as a result of the interaction with bottom longline gear at 17 per year. The leatherback mortality is very conservative because it is known that leatherbacks rarely ingest or bite hooks, but are usually foul hooked on their flippers or carapaces, reducing the likelihood of post-hooking release mortality. However, leatherback-specific data for this fishery is not available and therefore the most conservative estimate is used.

*Smalltooth Sawfish*

As of April 1, 2003, NMFS listed smalltooth sawfish as an endangered species (68 FR 15674) under the ESA. After reviewing the best scientific and commercial information, the status review team determined that the continued existence of the U.S. Distinct Population Segment of smalltooth sawfish was in danger of extinction throughout all or a significant portion of its range from a combination of the following four listing factors: the present or threatened destruction, modification, or curtailment of habitat or range; overutilization for commercial, recreational, scientific, or educational purposes; inadequacy of existing regulatory mechanisms; and other natural or manmade factors affecting its continued existence. NMFS is working on designating critical habitat for smalltooth sawfish.

Sawfish have been observed caught (12 known interactions, 11 released alive, one released in unknown condition) in shark bottom longline fisheries from 1994 through 2006 (Morgan pers. comm., Burgess and Morgan, 2004; Carlson ) (Figure 3.32). Based on these observations, expanded sawfish take estimates for 1994 – 2002 were developed for the shark bottom longline fishery (NMFS, 2003a). A total of 466 sawfish were estimated to have been taken in this fishery from 1994 – 2002, resulting in an average of 52 per year. All but one of the observed sawfish was released alive.

*Marine Mammals*

Four delphinids have been observed caught and released alive between 1994 and 2004 (G. Burgess, pers. comm.). Bycatch estimates for the shark bottom longline fishery have not been extrapolated for marine mammals.

*Seabirds*

Bycatch of seabirds in the shark bottom longline fishery has been virtually non-existent. A single pelican has been observed killed from 1994 through 2005. The pelican was caught in January 1995 off the Florida Gulf Coast (between 25° 18.68 N, 81° 35.47 W and 25° 19.11 N, 81° 23.83 W) (G. Burgess, University of Florida, pers. comm., 2001). No expanded estimates of seabird bycatch or catch rates are available for the bottom longline fishery.

### 3.4.6 Gillnet Fishery

#### 3.4.6.1 Domestic History and Current Management

The southeast shark gillnet fishery is comprised of several vessels based primarily out of ports in northern Florida (South Atlantic Region) that use nets typically 456 to 2,280 meters long and 6.1 to 15.2 meters deep, with stretched mesh from 12.7 to 22.9 cm. This fishery is currently prohibited in the state waters off South Carolina, Georgia, and Florida, thereby forcing some of these vessels to operate in deeper waters under Federal jurisdiction, where gillnets are less effective. The entire process (set to haulback) takes approximately 9 hours (Carlson and Baremore, 2002a).

The 2005 Directed Shark Gillnet Fishery Observer Program report described the gear and soak time deployed by drift gillnet, strike gillnet, and sink gillnet fishermen. Set duration was generally 0.3 hours and haulback averaged 2.9 hours. The average time from setting the net through completion of haulback was 10.2 hours. The most frequently used mesh size for drift gillnets was 12.7 cm. Strikenetters use the largest mesh size (22.9 cm) and the set times were 2.7 hours. Sink gillnets used to target sharks generally use 17.8 cm mesh size and were soaked for approximately 0.8 hours. This gear was also observed being deployed to target non-HMS (kingfish or Spanish mackerel); using a stretched mesh size of 7.6 cm, to comply with mesh size regulations for the Spanish mackerel fishery, and soaked for approximately 5.9 hours (Carlson and Bethea, 2006).

In the southeast shark gillnet fishery, NMFS modified the requirement to have 100 percent observer coverage at all times on March 30, 2001 (66 FR 17370), by reducing the level required to a statistically significant level outside of right whale calving season (100 percent observer coverage is still required during the right whale calving season from November 15 through March 31). This modification of observer coverage reduced administrative costs while maintaining statistically significant and adequate levels of coverage to provide reasonable estimates of sea turtle and marine mammal takes outside the right whale calving season. The level of observer coverage necessary to maintain statistical significance will be reevaluated annually and adjusted accordingly. Additionally, in 2001, NMFS established a requirement to conduct net checks every two hours to look for and remove any protected species.

#### 3.4.6.2 Recent Catch and Landings

The following section provides information on shark landings as reported in the shark gillnet observer program. For recent catch and landings data for the shark fishery as a whole, which includes landings from gillnet, BLL, and other gears combined, please refer to Section 3.4.7. A total of 24 driftnet sets were observed on five vessels from February through September, 2004. Driftnet vessels carried nets ranging in length from 547.2 – 2736 m; depths from 7.6 – 13.7 m and stretched mesh sizes from 12.7 – 22.9 cm. The most frequently used mesh size was 12.7 cm. For all observed driftnet sets, set duration averaged 0.4 hrs. Sets were made in seawater averaging 15.4 m deep. Haulback and processing of the catch averaged 3.4 hrs. Average soak time for the driftnet (time net was first set minus time haulback began) was 10.8 hrs.

The observed driftnet catch consisted of nine species of sharks. Three species of sharks made up 92.9 percent (by number) of the observed shark catch (Table 3.57). These species were the Atlantic sharpnose shark, blacknose shark, and finetooth shark. By weight, the shark catch was made up of Atlantic sharpnose shark, (55.3 percent), blacknose shark (17.1 percent), blacktip shark (10.7 percent), and finetooth shark (10.3 percent). Total observed catch composition (percent of numbers caught) was 79.0 percent sharks, 20.7 percent teleosts, 0.3 percent rays, and 0.03 percent protected species (*i.e.*, marine mammals, sea turtles, sawfish).

*Gillnet Bycatch*

On September 23, 2002, NMFS implemented a restricted area to reduce bycatch of right whales from November 15 through March 31 (67 FR 59471). In this area, only gillnets used in a strikenet fashion can operate during times when right whales are present. Operation in this area at that time requires 100 percent observer coverage. Vessels fishing in a strikenet fashion used nets 364.8 meters long, 30.4 meters deep, and with mesh size 22.9 cm. Observed catch in the strikenet fishery consisted of 6 species of sharks (96.7 percent of total number caught) and seven species of teleosts and rays (3.3 percent of total number caught). No marine mammals or sea turtles were observed caught. The blacktip shark made up 97.5 percent of the number of sharks caught, and 86 percent of the overall catch. Bycatch included crevalle jack, red drum, and great barracuda (Table 3.56).

There were 23 species of teleosts, two species of rays, and one species of marine mammal observed caught during the driftnet season (Table 3.58). Four species of teleosts and rays made up 90.8 percent by number of the overall non-shark species in observed strikenet catches. These species were little tunny (45.6 percent); king mackerel (23.3 percent); great barracuda (11.8 percent); and red drum (10.2 percent). For incidental driftnet catch species, the highest proportion discarded dead (with observed catch greater than 10 specimens) was Atlantic sailfish, (100.0 percent), king mackerel (78.3 percent), and cobia (28.7 percent). Red drum had the highest discard proportion alive (98.1 percent) (Carlson and Baremore, 2003). Observed driftnet sets caught 23 species of teleosts and rays and no sea turtles or marine mammals. Only the great barracuda were retained, with all remaining bycatch discarded alive (Carlson, 2002).

Outside of right whale calving season, observed drift gillnet catch consisted of 26 species of teleosts and rays and one species of marine mammal, which was discarded dead. Five species of teleosts and one species of ray made up 90.6 percent by number of the overall non-shark catch. Little tunny (44.1 percent), king mackerel (20.8 percent), great barracuda (12.5 percent), Atlantic moonfish (9.4 percent), and cobia (3.8 percent) dominated the bycatch (Carlson and Baremore, 2002). During drift gillnet fishing, the highest proportion of species discarded dead (for species with greater than 10 individuals) was for tarpon, crevalle jack, king mackerel, and red drum. Cownose rays and red drum had the highest proportion of discarded alive with 78.1 percent and 50.0 percent, respectively (Carlson and Baremore, 2002).

On January 22, 2006, a dead right whale was spotted offshore of Jacksonville Beach, Florida. The survey team identified the whale as a right whale calf, and photos indicated the calf as having one large wound along the midline and smaller lesions around the base of its tail. The right whale calf was located at 30°14.4’ N. Lat., 81° 4.2′′ W. Long., which was approximately 1 nautical mile outside of the designated right whale critical habitat, but within the Southeast U.S. Restricted Area. NMFS determined that both the entanglement and death of the whale occurred within the Southeast U.S. Restricted Area, and all available evidence suggested the entanglement and injury of the whale by gillnet gear ultimately led to the death of the animal.

On February 16, 2006, NMFS published a temporary rule (71 FR 8223) to prohibit, through March 31, 2006, any vessel from fishing with any gillnet gear in the Atlantic Ocean waters between 32°00’ N. Lat. (near Savannah, GA) and 27°51’ N. Lat. (near Sebastian Inlet, FL) and extending from the shore eastward out to 80°00’ W. long under the authority of the Atlantic Large Whale Take Reduction Plan (ALWTRP) (50 CFR 229.32 (g)) and the Endangered Species Act. NMFS took this action based on its determination that a right whale mortality was the result of an entanglement by gillnet gear within the Southeast U.S. Restricted Area.

The regulations at 50 CFR 229.32(g)(1) also require NMFS to close the Southeast U.S. Restricted Area for the rest of the time period, and for the time period November 15 through March 31 in each subsequent year, unless NMFS revises the restricted period or unless other measures are implemented. NMFS plans to seek assistance and recommendations from the ALWTRT at their next meeting in order to evaluate whether permanent closures within the Southeast U.S. Restricted Area are necessary.

*Loggerhead Sea Turtles*

Loggerhead sea turtles are rarely caught in the shark gillnet fishery. During the 1999 right whale calving season, no loggerhead sea turtles were observed caught in this fishery (Carlson and Lee, 1999), and no loggerheads were observed caught with strikenets during the 2000 – 2002 right whale calving seasons (Carlson 2000; Carlson and Baremore, 2001; Carlson and Baremore, 2002a). However, three loggerhead sea turtles were observed caught with drift gillnets during right whale calving season, one each year from 2000 to 2002 (Carlson, 2000; Carlson and Baremore, 2001; Carlson and Baremore, 2002a; Garrison, 2003). In 2004 there were no observed sea turtle interactions in either the strikenet or drift gillnet fisheries.

No loggerhead sea turtles were caught outside of the right whale calving season in 2002 (Carlson and Baremore, 2002b), and no loggerhead turtles were observed caught during or after the right whale calving season in 2003 or 2004 in the directed shark gillnet fishery (Carlson and Baremore 2003; Carlson, pers. comm). In 2005 five loggerheads were observed caught, and in 2006 three loggerheads were observed caught (Table 3.59). All but two were released alive. One loggerhead sea turtle mortality was reported in abandoned fishing gear in January 2004, and was not considered part of normal fishing operations.

*Leatherback Sea Turtles*

In the shark gillnet fishery, leatherback sea turtles are sporadically caught. During the 1999 right whale calving season, two leatherback sea turtles were caught in this fishery, and both were released alive (Carlson and Lee, 1999). No leatherback sea turtles were observed caught with strikenets during the 2000 – 2002 right whale calving seasons (Carlson, 2000; Carlson and Baremore, 2001; Carlson and Baremore, 2002a). Leatherback sea turtles have been observed caught in shark drift gillnets including 14 in 2001 and two in 2002 (Carlson, 2000; Carlson and

Baremore, 2001; Carlson and Baremore, 2002a; Garrison, 2003). NMFS temporarily closed the shark gillnet fishery (strikenetting was allowed) from March 9 to April 9, 2001, due to the increased number of leatherback interactions that year (66 FR 15045, March 15, 2001).

From 2003 – 2004, no leatherback sea turtles were observed caught in gillnets fished in strikenet or driftnet methods (Carlson and Baremore 2003; Carlson, pers. comm.).

*Smalltooth Sawfish*

To date there has been only one observed catch of a smalltooth sawfish in shark gillnet fisheries (Table 3.60). The sawfish was taken on June 25, 2003, in a gillnet off southeast Florida and was released alive (Carlson and Baremore, 2003). The set was characteristic of a typical drift gillnet set, with gear extending 30 to 40 feet deep in 50 to 60 feet of water. Prior to this event it was speculated that the depth at which drift gillnets are set above the sea floor may preclude smalltooth sawfish from being caught. Although sometimes described as a lethargic demersal species, smalltooth sawfish feed mostly on schooling fish, thus they would occur higher in the water column during feeding activity. In fact, smalltooth sawfish and Atlantic sharks may be attracted to the same schools of fish, potentially making smalltooth sawfish quite vulnerable if present in the area fished. The previous absence of smalltooth sawfish incidental capture records is more likely attributed to the relatively low effort in this fishery and the rarity of smalltooth sawfish, especially in Federal waters. These factors may result in little overlap of the species with the gear. The sawfish was cut from the net and released alive with no visible injuries. This indicates that smalltooth sawfish can be removed safely if entangled gear is sacrificed.

Given the high rate of observer coverage in the shark gillnet fishery, NMFS believes that smalltooth sawfish takes in this fishery are very rare. The fact that there were no smalltooth sawfish caught during 2001 when 100 percent of the fishing effort was observed indicates that smalltooth sawfish takes (observed or total) most likely do not occur on an annual basis. Based on this information, the 2003 BiOp estimated that one incidental capture of a sawfish (released alive) over the next five years, will occur as a result of the use of gillnets in this fishery (NMFS, 2003a).

*Marine Mammals*

Observed takes of marine mammals in the Southeast Atlantic shark gillnet fishery during 1999 – 2004, totaled 12 bottlenose dolphins and four spotted dolphins. Extrapolated observations from these data suggest serious injury and mortality of 25 bottlenose dolphin and one Atlantic spotted dolphin in the shark gillnet fishery from 1999 through 2002 (Garrison, 2003).

### 3.4.7 Fishery Data: Landings by Species

The following tables of finfish landings are taken from the 2005 National Report of the United States to ICCAT (NAT-038) (NMFS, 2005). The purpose of this section is to provide a summary of recent landings of HMS on a species by species basis for comparison to Sections 4.1 through 4.5 of the 2004 HMS SAFE report. Landings for sharks were compiled from the most recent stock assessment documents.

## 3.5 Economic Status of HMS Fisheries

The review of each rule, and of HMS fisheries as a whole, is facilitated when there is a baseline against which the rule or fishery may be evaluated. In this analysis, as in past SAFE reports, NMFS used 1996 as a baseline. NMFS believes that this baseline is appropriate because the Regulatory Flexibility Act (RFA) and Magnuson-Stevens Act were both amended in 1996, NMFS began to collect economic information voluntarily for vessels using the pelagic logbook in 1996, and regarding HMS specifically, no rules were implemented in 1996 that were classified as significant under RFA. Additionally, while the Atlantic Tunas, Swordfish, and Shark FMP and the Billfish Amendment 1 were finalized in 1999, scoping for these two major documents and its final rule began in 1997. It is possible that anticipation of these documents and any potential changes in their implementing regulations could have begun to impact the decisions made by HMS fishermen and any associated businesses.

In addition to using the 1996 baseline, this FEIS also provides six years of data, when possible, in order to facilitate the analysis of trends. It also should be noted that all dollar figures are reported in nominal dollars (*i.e.,* current dollars). If analysis of real dollar (*i.e.,* constant dollar) trends controlled for inflation is desired, price indexes for 1996 to 2004 are provided in. To determine the real price in base year dollars, divide the base year price index by the current year price index, and then multiply this result by the price that is being adjusted for inflation. From 1996 to 2004, the Consumer Price Index (CPI-U) indicates that prices have risen by 20.4 percent, the Gross Domestic Product (GDP) Implicit Price Deflator indicates that prices have risen 16.3 percent, and the Producer Price Index (PPI) for unprocessed finfish indicates a 20.8 percent rise in prices. From 2002 to 2003, the CPI, GDP Deflator, and the PPI for unprocessed finfish indicate prices rose by 2.3 percent, 2.0 percent, and declined by 2.8 percent respectively. From 2003 to 2004, the CPI, GDP Deflator, and the PPI for unprocessed finfish indicate prices rose by 2.7 percent, 2.6 percent, and 14.5 percent respectively.

**Table 3.74** **Inflation Price Indexes.** The CPI-U is the standard Consumer Price Index for all urban consumers (1982-1984=100) produced by U.S. Department of Labor Bureau of Labor Statistics. The source of the Producer Price Index (PPI) for unprocessed finfish (1982=100) is also the Bureau of Labor Statistics. The Gross Domestic Product Implicit Price Deflator (200=100) is produced by the U.S. Department of Commerce Bureau of Economic Analysis and obtained from the Federal Reserve Bank of St. Louis (**http://www.stlouisfed.org/**).

| | | | PPI Unprocessed Finfish |
|---|---|---|---|
| 1996 | 156.9 | 93.8 | 185.5 |
| 1997 | 160.5 | 95.4 | 165.7 |
| 1998 | 163 | 96.5 | 170.7 |
| 1999 | 166.6 | 97.9 | 191.7 |
| 2000 | 172.2 | 100.0 | 182.4 |

| 2002 | 179.9 | 104.2 | 201.5 |
| 2003 | 184 | 106.3 | 195.8 |
| 2004 | 188.9 | 109.1 | 224.1 |

### 3.5.1 Commercial Fisheries[4]

In 2003, the total commercial landings at ports in the 50 states by U.S. fishermen were 9.5 billion pounds valued at $3.3 billion. In 2004, the total commercial landings at ports in the 50 states by U.S. fishermen were 9.6 billion pounds and were valued at $3.7 billion. The overall value of landings between 2003 and 2004 had increased by nine percent. The total value of commercial HMS landings in 2004 was $43.9 million (Table 3.77). The 2004 ex-vessel price index indicated that 12 of the 17 finfish species tracked had increasing ex-vessel prices and five species had decreasing ex-vessel prices since 2003. The total edible finfish ex-vessel price index for 2004 was up eight percent from 2003.

The estimated value of the 2004 domestic production of all fishery products was $6.6 billion. This is $909 million less than the estimated value in 2003. The total import value of fishery products was $22.9 billion in 2004. This is an increase of $1.7 billion from 2003. The total import value in 1996 was $13.1 billion. The total export value of fishery products was $13.6 billion in 2004. This is an increase of $1.6 billion from 2003. The total export value in 1996 was $8.7 billion.

Consumers spent an estimated $61.9 billion for fishery products in 2004 including $42.8 billion at food service establishments, $18.9 billion in retail sales for home consumption, and $213.3 million for industrial fish products. The commercial marine fishing industry contributed $31.6 billion to the U.S. Gross National Product in 2004. In 1996, consumers spent an estimated $41.2 billion including $27.8 billion at food service establishments, $13.2 billion for home consumption, and $283.9 billion for industrial fish products. The commercial marine fishing industry contributed $21.0 billion to the U.S. Gross National Product in 1996.

[4] All the information and data presented in this section were obtained from NMFS 1997a and NMFS 2005b.

### 3.5.1.1 Ex-Vessel Prices

The average ex-vessel prices per pound dressed weight (dw) for 1996 and 1999 to 2004 by area, Atlantic HMS, and major gear types are summarized in Table 3.75. The average ex-vessel prices per lb dw for 1996 and 1999 to 2004 by species and area are summarized in Table 3.76. For both of these tables, prices are reported in nominal dollars. The ex-vessel price depends on a number of factors including the quality of the fish (*e.g.,* freshness, fat content, method of storage), the weight of the fish, the supply of fish, and consumer demand.

**Table 3.75 Average ex-vessel prices per lb dw for Atlantic HMS by gear and area.** Source: Dealer weighout slips from the Southeast Fisheries Science Center and Northeast Fisheries Science Center, and bluefin tuna dealer reports from the Northeast Regional Office. HND=Handline, harpoon, spears, trot lines, and trolls, PLL=Pelagic longline, BLL=Bottom longline, Net=Gillnets and pound nets, TWL=Trawls, SEN=Seines, TRP=Pots and traps, DRG=Dredge, and UNK=Unknown. Gulf of Mexico includes: TX, LA, MS, AL, and the west coast of FL. S. Atlantic includes: east coast of FL. GA, SC, and NC dealers reporting to Southeast Fisheries Science Center. Mid-Atlantic includes: NC dealers reporting to Northeast Fisheries Science Center, VA, MD, DE, NJ, NY, and CT. N. Atlantic includes: RI, MA, NH, and ME. For bluefin tuna, all NC landings are included in the Mid-Atlantic.

Table 3.75 and Table 3.76 indicate that the average ex-vessel prices for bigeye tuna have generally increased since 1996. Prices from 2003 to 2004 have increased in all four regions. The gears used also influenced the average price of bigeye tuna.

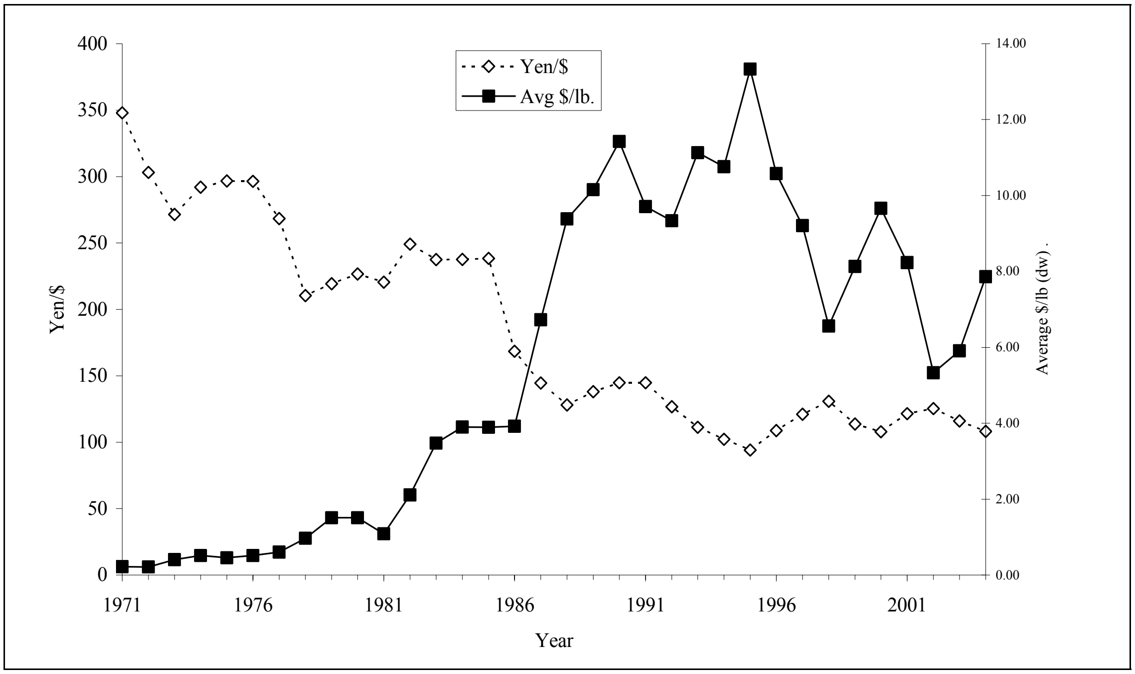

**Figure 3.33 Average Annual Yen/$ Exchange Rate and Average U.S. BFT Ex-vessel $/lb (dw) for all gears: 1971-2003.** Source: Federal Reserve Bank (www.stls.frb.org) and Northeast Regional Office.

Average ex-vessel prices for bluefin tuna have generally declined since 1996. Since 2002, however, prices increased in all regions except the North Atlantic (Table 3.76). The gear used also made a difference in the ex-vessel price (Table 3.75). In the North Atlantic and Mid-Atlantic, bluefin tuna caught with handgear had higher average prices than those caught with longline. This trend has been fairly consistent over the years between 1996 and 2004. The ex-vessel prices for bluefin tuna can be influenced by many factors, including market supply and the Japanese Yen/U.S. Dollar (¥/$) exchange rate. Figure 3.33 shows the average ¥/$ exchange rate, plotted with average ex-vessel bluefin tuna prices, from 1971 to 2003.

The average ex-vessel prices for yellowfin tuna have increased in 2004 in the Gulf of Mexico, Mid-Atlantic and North Atlantic while increasing slightly in the South Atlantic (Table 3.76). Yellowfin tuna caught with longline gear had higher average ex-vessel prices than fish caught with other gear types in 2004 (Table 3.75). The average ex-vessel price for other tunas decreased in all regions except the Gulf of Mexico in 2004 (Table 3.76). The average price of other tunas is lowest in the South Atlantic compared to other regions. The type of gear used did not appear to consistently influence the average ex-vessel prices of other tuna. Average ex-vessel prices for swordfish increased in 2004 in all regions (Table 3.76). Swordfish caught using handline gear had higher average ex-vessel prices than other gear types, except in the Mid-Atlantic where it was trawls (Table 3.75).

The average ex-vessel price for LCS slightly decreased in the Gulf of Mexico in 2004 and North Atlantic. However, prices for LCS increased in the Mid-Atlantic and South Atlantic (Table 3.76). The average ex-vessel prices for pelagic sharks increased in the Mid-Atlantic and North Atlantic regions in 2004 (Table 3.76), while prices decreased in Gulf of Mexico and South Atlantic. The 2004 prices for pelagic sharks are not significantly different than 1996 prices and are actually lower than 1996 when adjusting for inflation. The average ex-vessel prices for small coastal sharks (SCS) rebounded in all regions in 2004 (Table 3.76). Gear type did not consistently affect ex-vessel price of small coastal sharks in 2004 (Table 3.75).

#### 3.5.1.2 Revenues

Table 3.77 summarizes the average annual revenues of the Atlantic HMS fishery based on average ex-vessel prices and the weight reported landed as per the U.S. National Report (NMFS 2005), the Shark Evaluation Reports, information given to ICCAT (Cortes, 2005), as well as price and weight reported to the NMFS Northeast Regional Office by Atlantic bluefin tuna dealers. These values indicate that the estimated total annual revenue of Atlantic HMS fisheries has decreased 34 percent from approximately \$66.4 million in 1996 to approximately \$43.9 million in 2004. From 2003 to 2004, the tuna fishery's total revenue decreased significantly. A majority of that decrease can be attributed to reduced commercial landings of bluefin tuna and yellowfin tuna. From 2003 to 2004, the annual revenues from shark decreased by over 21 percent. In contrast, the annual revenues from swordfish from 2003 to 2004 increased by five percent after having been in decline for several years.

**Table 3.77 Estimates of the total ex-vessel annual revenues of Atlantic HMS fisheries.** Sources: NMFS, 1997; NMFS 2004a; Cortes, 2003; and bluefin tuna dealer reports from the Northeast Regional Office.

Note: Average ex-vessel prices may have some weighting errors, except for bluefin tuna which is based on a fleet-wide average. Other tunas includes skipjack and albacore. ** Swordfish estimates do not include dead discards.

#### 3.5.1.3 Wholesale Market

Currently, NMFS does not collect wholesale price information from dealers. However, the wholesale price of some fish species is available off the web (http://www.st.nmfs.gov/st1/market_news/index.html). The wholesale prices presented in Table 3.78 are from the annual reports of the Fulton Fish Market. As with ex-vessel prices, wholesale prices depend on a number of factors including the quality of the fish, the weight of the fish, the supply of fish, and consumer demand.

As reported by the Fulton Fish Market, Table 3.78 indicates that the average wholesale price of HMS sold in Atlantic and Gulf of Mexico states generally decreased from 1996 to 2003, except for blacktip shark. Prices have appeared to have rebounded in 2004, breaking from the declining trend. During that same period, the wholesale price of swordfish weighing over 100 pounds decreased 19 percent, swordfish weighing between 50 and 99 pounds decreased 25 percent, and swordfish cuts decreased 15 percent. The wholesale price of blacktip shark increased 27 percent from 1996 to 2003, with most of the increase occurring in 2003. The wholesale price of mako shark decreased 14 percent from 1996 to 2003, however 2003 wholesale prices were up from 2002. The wholesale price of thresher shark has decreased 22 percent from 1996 to 2003. Wholesale yellowfin tuna prices have remained relatively stable from 1996 to 2003. The yellowfin tuna wholesale price of #2 quality fish had decreased eight percent while the price of #2 cuts has increased seven percent from 1996 to 2003. Bigeye tuna wholesale prices from 1999 to 2003 have increased significantly for both high grade cuts and fish.

**Table 3.78 The overall average wholesale price per lb of fresh HMS sold in Atlantic and Gulf of Mexico states as reported by the Fulton Fish Market.** Source: NMFS, 2004.

| | | | | | | | | 2004 Price/lb |
|---|---|---|---|---|---|---|---|---|
| Blacktip | - | $1.05 | $1.04 | $1.04 | $1.05 | $1.00 | $1.33 | $1.08 |
| Mako | - | $2.77 | $2.74 | $3.18 | $3.00 | $2.00 | $2.37 | $2.24 |
| Thresher | - | $1.00 | $0.91 | $0.82 | $1.25 | $1.25 | $0.78 | $1.24 |
| Swordfish | 100# and up | $6.28 | $5.26 | $5.26 | $5.42 | $5.19 | $5.08 | $5.66 |
| | 50-99# | $6.02 | $4.54 | $4.72 | $4.81 | $4.59 | $4.50 | $5.15 |
| | 26-49# | $5.50 | $3.36 | $3.58 | $4.05 | $3.50 | - | $3.25 |
| | Cuts | $7.74 | $6.55 | $6.54 | $6.73 | $6.84 | $6.55 | $7.13 |
| Yellowfin tuna | #1: BTF | $7.00 | $5.97 | $5.69 | $5.50 | $7.42 | - | $6.00 |
| | #1: Cuts | $9.38 | $8.23 | $8.00 | $8.23 | $10.67 | - | $8.50 |
| | #2: BTF | $5.00 | $4.24 | $4.36 | $3.97 | $4.92 | $4.60 | $4.62 |
| | #2: Cuts | $6.52 | $6.22 | $6.20 | $6.00 | $7.29 | $6.98 | $7.32 |

| | #2: Cuts | - | $6.00 | - | - | - | - | - |

Note: #'s indicate quality (1 is highest, 3 is lowest); BTF is by the fish.

### 3.5.2 Recreational Fisheries

Although NMFS believes that recreational fisheries have a large influence on the economies of coastal communities, NMFS has only recently been able to gather additional information on the costs and expenditures of anglers or the businesses that rely on them.

An economic survey done by the U.S. Fish and Wildlife Service[2] in 2001 found that for the entire United States 9.1 million saltwater anglers (including anglers in state waters) went on approximately 72 million fishing trips and spent approximately $8.4 billion (USFWS, 2001). Expenditures included lodging, transportation to and from the coastal community, vessel fees, equipment rental, bait, auxiliary purchases (*e.g.*, binoculars, cameras, film, foul weather clothing, *etc.*), and fishing licenses (USFWS, 2001). Saltwater anglers spent $4.5 billion on trip-related costs and $3.9 billion on equipment (USFWS, 2001). Approximately 76 percent of the saltwater anglers surveyed fished in their home state (USFWS, 2001). The next USFWS survey is expected in 2006.

Specific information regarding angler expenditures for trips targeting HMS species was extracted from the recreational fishing expenditure survey add-on (1998 in the Northeast, 1999 – 2000 in the Southeast) to the National Marine Fisheries Service's Marine Recreational Fisheries Statistics Survey (MRFSS). These angler expenditure data were analyzed on a per person per trip-day level and reported in 2003 dollars. The expenditure data include the costs of tackle, food, lodging, bait, ice, boat fuel, processing, transportation, party/charter fees, access/boat launching, and equipment rental. The overall average expenditure on HMS related trips is estimated to be $122 per person per day. Specifically, expenditures are estimated to be $686 per person per day on billfish directed trips (based on a low sample size), $85 on pelagic shark directed trips, $95 on large coastal shark directed trips, $81 on small coastal sharks, and $106 on tuna trips.

The American Sportfishing Association (ASA) also has a report listing the 2001 economic impact of sportfishing on specific states. This report states that all sportfishing (in both Federal and state waters) has an overall economic importance of $116 billion dollars (ASA, 2001). Florida, Texas, North Carolina, New York, and Alabama are among the top ten states in terms of overall economic impact for both saltwater and freshwater fishing (ASA, 2001). Florida is also one of the top states in terms of economic impact of saltwater fishing with $2.9 billion in angler expenditures, $5.4 billion in overall economic impact, $1.5 billion in salaries and wages related to fishing, and 59,418 fishing related jobs (ASA, 2001). California followed Florida with $0.8 billion in angler expenditures, $1.7 billion in overall economic impact, $0.4 billion in salaries and wages, and 15,652 jobs (ASA, 2001). Texas and New Jersey were the next highest states in terms of economic impact (ASA, 2001).

At the end of 2004, NMFS began collecting market information regarding advertised charterboat rates. This preliminary analysis of the data collected includes 99 observations of advertised rates on the internet for full day charters. Full day charters vary from six to 14 hours long with a typical trip being 10 hours. Most vessels can accommodate six passengers, but this

[2] This survey interviewed over 77,000 households during phase 1 and approximately 25,070 sports persons during phase 2. The response rate during phase two of the survey was 75 percent.

also varies from two to 12 passengers. Table 3.79 summarizes the average charterboat rate for full day trips on vessels with HMS Charter/Headboat permits. The average price for a full day boat charter was $1,053 in 2004. Sutton *et al.*, (1999) surveyed charterboats throughout Alabama, Mississippi, Louisiana, and Texas in 1998 and found the average charterboat base fee to be $762 for a full day trip. Holland *et al.* (1999) conducted a similar study on charterboats in Florida, Georgia, South Carolina, and North Carolina and found the average fee for full day trips to be $554, $562, $661, and $701, respectively. Comparing these two studies conducted in the late 1990s to the average advertised daily HMS charterboat rate in 2004, it is apparent that there has been a significant gain in charterboat rates.

**Table 3.79 Average Atlantic HMS charterboat rates for day trips.** Source: NMFS searches for advertised daily charter rates of HMS Charter/Headboat permit holders. (Observations=99)

| | **2004 Average Daily Charter Rate** |
|---|---|
| AL | $1,783 |
| CT | $1,500 |
| DE | $1,060 |
| FL | $894 |
| LA | $1,050 |
| MA | $777 |
| MD | $1,167 |
| ME | $900 |
| NC | $1,130 |
| NJ | $1,298 |
| NY | $1,113 |
| RI | $917 |
| SC | $1,300 |
| TX | $767 |
| VA | $825 |
| **Overall Average** | **$1,053** |

In 2003, Ditton and Stoll published a paper that surveyed the literature regarding what is currently known about the social and economic aspects of recreational billfish fisheries. It was estimated that 230,000 anglers in the United States spent 2,136,899 days fishing for billfish in 1991. This is approximately 3.6 percent of all saltwater anglers over age 16. The states with the highest number of billfish anglers are Florida, California, North Carolina, Hawaii, and Texas in descending order. Billfish anglers studied in the U.S. Atlantic, Puerto Rico, and Costa Rica fished between 39 and 43 days per year.

Billfish recreational anglers tend to spend a great deal of money on trips. Ditton and Stoll (2003) report that a 1990 study of U.S. total trip costs for a typical billfish angler estimated a mean expenditure of $2,105 per trip for the Atlantic and $1,052 per trip for Puerto Rico. The aggregate economic impact of billfish fishing trips in the U.S. Atlantic is conservatively estimated to be $22.7 million annually.

In addition to the economic impact of recreational billfish angling, Ditton and Stoll (2003) report that using a contingent valuation method they estimated consumer's surplus or net economic benefit to maintain current billfish populations in the U.S. Atlantic to be $497 per billfish angler per year in the U.S. Atlantic and $480 in Puerto Rico. They also estimate that the number of annual billfish anglers in the U.S. Atlantic to be 7,915 and 1,627 in Puerto Rico. The aggregate willingness-to-pay for maintaining current billfish populations is $3.93 million in the U.S. Atlantic and 0.78 million in Puerto Rico. The aggregate direct impact of billfish expenditures is estimated to be $15.13 million for the U.S. Atlantic and $32.40 million for Puerto Rico. Thus, the total aggregate economic value of billfish angler fishing is $19.06 million per year for the U.S. Atlantic and $33.18 million per year for Puerto Rico.

Generally, HMS tournaments last from three to seven days, but lengths can range from one day to an entire fishing season. Similarly, average entry fees can range from approximately $0 to $5,000 per boat (average approximately $500/boat – $1,000/boat), depending largely upon the magnitude of the prize money that is being awarded. The entry fee would pay for a maximum of two to six anglers per team during the course of the tournament. Additional anglers can, in some tournaments, join the team at a reduced rate of between $50 and $450. The team entry fee did not appear to be directly proportional to the number of anglers per team, but rather with the amount of money available for prizes and, possibly, the species being targeted. Prizes may include citations, T-shirts, trophies, fishing tackle, automobiles, boats, or other similar items, but most often consists of cash awards. In general, it appears that billfish and tuna tournaments charge higher entry fees and award more prize money than shark and swordfish tournaments, although all species have a wide range.

Cash awards distributed in HMS tournaments can be quite substantial. Several of the largest tournaments, some of which are described below, are part of the World Billfish Series Tournament Trail whereby regional winners are invited to compete in the World Billfish Series Grand Championship for a new automobile and a bronze sculpture. Other tournament series include the International Game Fish Association (IGFA) Rolex Tournament of Champions, and the South Carolina Governor's Cup. White marlin is a top billfish species from Cape Hatteras, North Carolina to the eastern tip of Georges Bank from June through October each year. The White Marlin Open in Ocean City, Maryland, which is billed as the "world's richest fishing tournament," established a new world record payout for catching a fish when it awarded $1.32 million in 2004 to the vessel catching the largest white marlin. The 21st Annual Pirates Cove Billfish Tournament in North Carolina awarded over $1 million in prizes in 2004, with the top boat garnering over $400,000 for winning in six categories. Total prize money awarded in the Big Rock Tournament in North Carolina has exceeded $1 million since 1998.

Blue marlin, sailfish, and tunas are also often targeted in fishing tournaments, including those discussed above. In 2004, blue marlin was the HMS most frequently identified as a prize category in registered HMS tournaments. Forty-five teams participated in the 2004 Emerald Coast Blue Marlin Classic at Sandestin, Florida, with over $482,000 in cash prizes and the top boat receiving over $58,000. The 34th Annual Pensacola (Florida) International Billfish

Tournament indicated that it would award over $325,000 in cash and prizes in 2004. The World Sailfish Championship in Key West, Florida has a $100,000 guaranteed first prize for 2005. In South Carolina, the Megadock Billfishing Tournament offers a $1,000,000 prize for any boat exceeding the current blue marlin state record. The 2004 Florida Billfish Masters Tournament in Miami, Florida awarded over $123,000 in prize money, with the top boat receiving over $74,000. Sixty-two boats competed in the 2003 Babylon Tuna Club Invitational in Babylon, New York for over $75,000 in cash prizes, and the Mid-Atlantic Tuna Tournament sponsored by the South Jersey Marina in Cape May, New Jersey anticipates awarding over $25,000 in prizes in 2005.

Several tournaments target sharks. Many shark tournaments occur in New England, New York, and New Jersey, although other regions hold shark tournaments as well. In 2004, the 24th Annual South Jersey Shark Tournament hosted over 200 boats and awarded over $220,000 in prize money, with an entry fee of $450 per boat. The "Mako Fever" tournament, sponsored by the Jersey Coast Shark Anglers, in 2004 awarded over $55,000 in prizes, with the first place vessel receiving $25,000. In 2004, the 18th Annual Monster Shark Tournament in Martha's Vineyard, Massachusetts was broadcast on ESPN, and featured a new fishing boat valued at over $130,000 awarded to the winner.

Swordfish tournaments have gained increased popularity in recent years, especially on the east coast of Florida, as the swordfish population has recovered. Events include the Islamorada Swordfish Tournament that began in 2004, and the Miami Swordfish Tournament that began in 2003. Both of these tournaments anticipated awarding over $30,000 in total cash and prizes, assuming that 50 boats would participate.

In addition to official prize money, many fishing tournaments may also conduct a "calcutta" whereby anglers pay from $200 to $5,000 to win more money than the advertised tournament prizes for a particular fish. Tournament participants do not have to enter calcuttas. Tournaments with calcuttas generally offer different levels depending upon the amount of money an angler is willing to put down. Calcutta prize money is distributed based on the percentage of the total amount entered into that Calcutta. Therefore, first place winner of a low level Calcutta (entry fee ~$200) could win less than a last place winner in a high level calcutta (entry fee ~$1000). On the tournament websites, it was not always clear if the total amount of prizes distributed by the tournament included prize money from the calcuttas or the estimated price of any equipment. As such, the range of prizes discussed above could be a combination of fish prize money, Calcutta prize money, and equipment/trophies.

Fishing tournaments can sometimes generate a substantial amount of money for surrounding communities and local businesses. Besides the entry fee to the tournament and possibly the calcutta, anglers may also pay for marina space and gas (if they have their own vessel), vessel rental (if they do not have their own vessel), meals and awards dinners (if not covered by the entry fee), hotel, fishing equipment, travel costs to and from the tournament, camera equipment, and other miscellaneous expenses. Fisher and Ditton (1992) found that the average angler who attended a billfish tournament spent $2,147 per trip (2.59 days), and that billfish tournament anglers spent an estimated $180 million (tournament and non-tournament trips) in 1989. Ditton and Clark (1994) estimated annual expenditures for Puerto Rican billfish fishing trips (tournaments and non-tournaments) at $21.5 million. More recently, Ditton, *et al.*,

(2000) estimated that the total expenditure (direct economic impact) associated with the 1999 Pirates Cove Billfish Tournament, not including registration fees, was approximately $2,072,518. The total expenditure (direct economic impact) associated with the 2000 Virginia Beach Red, White, and Blue Tournament was estimated at approximately $450,359 (Thailing, *et al*., 2001). These estimated direct expenditures do not include economic effects that may ripple through the local economy leading to a total impact exceeding that of the original purchases by anglers (*i.e*., the multiplier effect). Less direct, but equally important, fishing tournaments may serve to generally promote the local tourist industry in coastal communities. In a survey of participants in the 1999 Pirates Cove Billfish Tournament, Ditton, *et al*., (2000) found that almost 80 percent of tournament anglers were from outside of the tournament's county. For this reason, tourism bureaus, chambers of commerce, resorts, and state and local governments often sponsor fishing tournaments.

## 3.6 Community and Social Update

According to National Standard 8 (NS 8), conservation and management measures should, consistent with conservation requirements, attempt to both provide for the continued participation of a community and, to the extent practicable, minimize the economic effects on the community. The information presented here addresses new data concerning the social and economic well-being of participants in the fishery and considers the impact of significant regulatory measures enacted in the past year.

### 3.6.1 Overview of Current Information and Rationale

The Magnuson-Stevens Act requires, among other things, that all FMPs include a fishery impact statement intended to assess, specify, and describe the likely effects of the measures on fishermen and fishing communities (§303(a)).

The National Environmental Policy Act (NEPA) also requires federal agencies to consider the interactions of natural and human environments by using a "systematic, interdisciplinary approach which will ensure the integrated use of the natural and social sciences...in planning and decision-making" (§102(2)(A)). Moreover, agencies need to address the aesthetic, historic, cultural, economic, social, or health effects which may be direct, indirect, or cumulative. Consideration of social impacts is a growing concern as fisheries experience increased participation and/or declines in stocks. The consequences of management actions need to be examined to better ascertain and, if necessary, mitigate impacts of regulations on affected constituents.

Social impacts are generally the consequences to human populations that follow from some type of public or private action. Those consequences may include alterations to the ways in which people live, work or play, relate to one another, and organize to meet their needs. In addition, cultural impacts which may involve changes in values and beliefs that affect people's way of identifying themselves within their occupation, communities, and society in general are included under this interpretation. Social impact analyses help determine the consequences of policy action in advance by comparing the status quo with the projected impacts. Although public hearings and scoping meetings provide input from those concerned with a particular action, they do not constitute a full overview of the fishery.

While geographic location is an important component of a fishing community, the transient nature of HMS may necessitate permitted fishermen to shift location in an attempt to follow the fish. Because of this characteristic, management measures for HMS often have the most identifiable impacts on fishing fleets that use specific gear types. The geographic concentrations of HMS fisheries may also vary from year to year as the behavior of these migratory fish is unpredictable. The relationship between these fleets, gear types, and geographic fishing communities is not always a direct one; however, they are important variables for understanding social and cultural impacts. As a result, the inclusion of typical community profiles in HMS management decisions is somewhat difficult as geographic factors and the use of a specific gear type have to be considered.

NMFS (2001) guidelines for social impact assessments specify that the following elements are utilized in the development of FMPs and FMP amendments:

1. The size and demographic characteristics of the fishery-related work force residing in the area; these determine demographic, income, and employment effects in relation to the work force as a whole, by community and region.
2. The cultural issues of attitudes, beliefs, and values of fishermen, fishery-related workers, other stakeholders, and their communities.
3. The effects of proposed actions on social structure and organization; that is, on the ability to provide necessary social support and services to families and communities.
4. The non-economic social aspects of the proposed action or policy; these include life-style issues, health and safety issues, and the non-consumptive and recreational use of living marine resources and their habitats.
5. The historical dependence on and participation in the fishery by fishermen and communities, reflected in the structure of fishing practices, income distribution and rights.

The information used in the 1999 FMP and the 1999 Billfish Amendment was obtained through a contract with Dr. Doug Wilson, from the Ecopolicy Center for Agriculture, Environmental and Resource Issues at Rutgers, the State University of New Jersey. Dr. Wilson and his colleagues completed their field work in July 1998. Their study considered HMS that have important commercial and recreational fisheries extending along the Atlantic and Gulf Coast from Maine to Texas and in the Caribbean. The study investigated the social and cultural characteristics of fishing communities in five states and one U.S. territory: Massachusetts, New Jersey, North Carolina, Florida, Louisiana, and Puerto Rico. These areas were selected because they each have important fishing communities that could be affected by measures included in the 1999 FMP and the 1999 Billfish Amendment, and because they are fairly evenly spread along the Atlantic and Gulf Coast and the Caribbean. For each state or territory, a profile of basic sociologic information was compiled, with at least two coastal communities visited for further analysis. Towns were selected based on HMS landings data, the relationship between the geographic communities and the fishing fleets, the existence of other community studies, and inputs from the Advisory Panels for HMS and Billfish. Complete descriptions of the study results can be found in Chapter 9 of the 1999 FMP and Chapter 7 of the Billfish Amendment.

In 2002, NMFS contracted the Virginia Institute of Marine Science (VIMS) at the College of William and Mary to re-evaluate several of the baseline communities and, specifically, to determine if the 1999 HMS FMP had a negative social impact on the communities dependent upon HMS. The 2005 report provided a brief overview and examination of changes in social and economic structures of communities which land HMS. The analysis of change since the 1999 HMS FMP regulations were implemented was based on demographics, landings information, and informal interviews with individuals from three different communities. Some of the report's findings are incorporated into the community profiles in Chapter 9 of this document.

### 3.6.2 Social Impacts of Selected 2005 Regulatory Actions

*Final Rule Implementing Atlantic Bluefin Tuna Quota Specifications for 2004 (70 CFR 43, March 7, 2005)*

This action set BFT quotas for each of the established domestic fishing categories and sets General category effort controls for the 2004 fishing year (June 1, 2004 – May 31, 2005) and established a catch-and-release provision, in addition to the tag-and release provision, for recreational and commercial BFT handgear vessels during a respective quota category closure.

The action was not expected to have any significant, positive or negative, social or economic impacts. The final action was expected to have modest positive social and economic impacts, by implementing the ICCAT-recommended adjusted BFT TAC for the United States in the western Atlantic management area of 1,489.6 mt. The action was not expected to have highly controversial effects on the human environment. There were no highly uncertain effects associated with this action due to the fact that the BFT fishery has been in operation for years. Thus, implementing the 2002 ICCAT BFT quota recommendation is consistent with the past, would not set a new precedence, and would provide positive economic impacts due to the application of the additional BFT quota. Although controversial issues associated with the BFT fishery remain, they are beyond the scope of this particular rulemaking and will be addressed in future regulatory and FMP amendments. The action is not expected to have substantial adverse impacts on public health and safety. Fishing activity or behavior would not change, although fishing effort may increase slightly as a result of this action.

*Final Rule Implementing Atlantic Bluefin Tuna Quota Specifications and General Category Effort Controls for 2005 (70 FR 108, June 7, 2005)*

This action set BFT quotas for each of the established domestic fishing categories and set General category effort controls for the 2005 fishing year (June 1, 2005 – May 31, 2006). NMFS also established the restricted fishing days to extend the General category BFT fishery into the late season for the southern Atlantic region. This action implemented the recommendations of the International Commission for the Conservation of Atlantic Tunas (ICCAT), as required by the Atlantic Tunas Convention Act, and were implemented to achieve domestic management objectives under the Magnuson-Stevens Fishery Conservation and Management Act.

NMFS prepared an EA for the final rule, concluding that the action is not expected to have any significant, positive or negative, social or economic impacts. The selected action was expected to have modest positive social and economic impacts, by implementing the ICCAT-recommended adjusted BFT TAC for the United States in the western Atlantic management area of 1,489.6 mt and is consistent with the ICCAT recommendation regarding the eight-percent tolerance of school BFT harvest. The action is not expected to be highly controversial on the human environment. There are no highly uncertain effects associated with this action due to the fact that the BFT fishery has been in operation for years. The action is not expected to have substantial adverse impacts on public health and safety. Fishing activity or behavior would not change, although fishing effort may increase slightly. For further background information, please see the Environmental Assessment and associated Final Regulatory Flexibility Analysis for this rule, http://www.nmfs.noaa.gov/sfa/hms/Tuna/05_Specs_Final_EA.RIR.FRFA.0523.pdf.

### 3.6.3 Summary of New Social and Economic Data Available

#### 3.6.3.1 2005 Social Science Publications

The following two reports were delivered in 2005. An additional two reports, completing the community profiles for the Gulf of Mexico, are currently in peer review. Both reports are summarized in the abstract below.

Impact Assessment. 2005. *Identifying communities associated with the fishing industry in Alabama and Mississippi.* La Jolla, California. (NOAA-NMFS-Contract WC133F-02-SE-0297). p.661.

Impact Assessment. 2005. *Identifying communities associated with the fishing industry in Louisiana*. La Jolla, California. (NOAA-NMFS-Contract WC133F-02-SE-0297). p. 661.

> *Abstract*. The research has been conducted for NOAA Fisheries Southeast Regional Office (SERO), in fulfillment of its goal to effectively manage the various fisheries upon which residents of certain towns and cities in the Gulf of Mexico have depended and/or continue to depend, to greater and lesser degrees, for economic and social purposes. A systematic methodology was developed to investigate and describe Gulf communities likely to exhibit some or all of the attributes of "fishing communities" as defined by the Magnuson-Stevens Fishery Conservation and Management Act as Amended (the Magnuson Act; MSFCMA), and by National Standard 8 (NS-8). The project methodology emphasized: (a) collection and geospatial analysis of various fishing license, landings, economic, and demographic attribute data, and (b) collection and analysis of a variety of descriptive economic and social data considered viable indicators of fishing community status. The scope of this study is quite large, encompassing 30 communities in three counties in Alabama, 14 communities in three counties in Mississippi, and 106 communities in Louisiana. The overarching goal of the project was to provide the information needed to make preliminary determinations about whether, or to what degree, each community fits the federal definition of "fishing community." This report provides: (a) fisheries-relevant narrative description of historic and contemporary life in the study parishes, cities, and towns, (b) tabular and spatial description of fisheries infrastructure and services, and fleet characteristics specific to those study areas; and (c) preliminary assessment of the manner in, and degree to which, each study town or city does or does not approximate the National Standard 8 definition of fishing community. As the final version of these reports is being submitted

immediately following the passage of Hurricane Katrina in late August of 2005, the reports and associated data may also serve as a timely and accurate baseline for assessing the effects of the event on the study counties, cities, and towns, and their residents.

Jacob, S., M. Jepson, and F.L. Farmer. 2005. *What you see is not always what you get: Aspect dominance as a confounding factor in the determination of fishing dependent communities. Human Organization* 64(4):374-385.

*Abstract*. Many residents of coastal towns believe that they live in communities that are economically dependent upon commercial fishing. However, employment data indicate that fishing is a relatively minor economic component of many of these communities. We apply the concept of aspect dominance from the field of ecology to help explain this discrepancy. In addition we explore other forms of ecological dominance in regard to perceptions of fishing dependence. A key idea is that residents and sometimes researchers confuse forms of ecological dominance with economic dependence. Our study relied upon secondary and key informant data for six Florida coastal communities. In addition, we conducted a random telephone sample with 1,200 residents of these villages to establish their perceptions of the importance of commercial fishing to their communities.

Sutton, S.G., and R.B. Ditton. 2005. *The substitutability of one type of fishing for another*. North American Journal of Fisheries Management 25:536-546.

*Abstract*. We investigated the willingness of saltwater anglers in Florida and Texas to substitute other types of fishing for the type of fishing they most preferred. Anglers were asked if there was a suitable substitute for their most preferred species and, if so, what species would provide them with the same satisfaction and enjoyment as their most preferred species at the same cost. Most anglers (86 percent) reported that other species would provide acceptable substitutes for their preferred species and were able to identify acceptable substitutes from a list of common saltwater species in Texas and Florida. Logistic regression was used to determine the effects of demographic and fishing participation variables on willingness to substitute. Willingness to substitute was positively related to years of education and negatively related to age and the importance placed on trophy-seeking experiences. Also, females were more willing to substitute than males. Results suggest that for some species substitution behavior in response to biologically or managerially imposed constraints on fishing activity could result in increased effort for other species in the saltwater fisheries of Texas and Florida.

#### 3.6.3.2 Summary of Social Data and Information for FEIS

This document consolidates all of the community profiles from previous HMS management plans or amendments and updates the community information, where possible. To ensure continuity with the 1999 HMS FMP and previous amendments, if a community was selected and described as being involved with an HMS fishery, the same community was included in this assessment. The communities profiled were originally selected due to the proportion of HMS landings, the relationship between the geographic communities and the fishing fleets, the existence of other community studies, and input from the HMS and Billfish Advisory Panels. The communities selected for detailed study are Gloucester and New Bedford, Massachusetts; Barnegat Light and Brielle, New Jersey; Wanchese, and Hatteras Township, North Carolina; Pompano Beach, Fort Pierce, Madeira Beach, Panama City Beach, and Islamorada, Florida; Boothville/Venice and Dulac, Louisiana; and Arecibo, Puerto Rico. These communities are not intended to be an exhaustive list of every HMS-related community in the United States; rather the objective is to give a broad perspective of representative areas.

The demographic profiles in this document have been modified to include the same baseline information for each community profiled; as a result, most of the tables include more information than portrayed in the 1999 HMS FMP and its amendments. The demographic tables still use both 1990 and 2000 Bureau of the Census data for comparative purposes. The descriptive community profiles include the same information provided by the Wilson, *et al.,* (1998) and Kirkley (2005) analyses with some new information provided by Impact Assessment, Inc (2004) on the Gulf of Mexico communities. Unlike the Wilson, *et al.,* (1998) study used in the 1999 HMS FMP, it was not possible to undertake field research for this assessment.

This assessment also reviewed the HMS permit databases to incorporate information about residence. This information was also used to identify additional HMS-related fishing communities that should be profiled in the future. Six GIS maps were generated to identify the communities where angler, charter/headboat, HMS dealers (tunas, shark, and swordfish combined), commercial tuna (all gear categories combined), directed and incidental shark, and swordfish (directed, incidental, and handgear combined) permit holders reside (Figure 9.1 to Figure 9.6). In past community profile and social impact analyses, it was difficult to identify where recreational HMS fishermen were located because no data were available for the number of recreational fishermen, as well as recreational landings by community. Previous social impact assessments report on charter fishing operations, fishing tournaments, and related activities to identify the scope of recreational fishing for each of the communities described. The information provided by the HMS permit databases should facilitate the identification of recreational HMS communities that should be profiled in the future.

#### 3.6.3.3 HMS Community Profile Needs

For future social impact analyses, the HMS permit databases, landings information, and HMS APs should be consulted to determine the most appropriate community profiles for HMS-related fisheries. The 2005 HMS permit data indicate that several new community profiles should be developed and some of the previously profiled communities may no longer be as significantly involved in the fishery as they were in the past (Figure 9.1 to Figure 9.6). Wakefield, Rhode Island should be considered due to the number of commercial tuna and swordfish permit holders in the area. Montauk, New York has a large concentration of charter/headboat, commercial tuna, and HMS dealer permit holders in the community. A large number of Cape May, New Jersey residents hold an HMS angling, charter/headboat, shark and/or swordfish permits. Morehead City, North Carolina is home to a number of HMS angling, charter/headboat, and commercial tuna permit holders. Each of these towns is actively involved with more than one sector of the HMS fisheries and therefore be impacted be any changes to HMS regulations.

While the permit holders in Puerto Rico and the Virgin Islands are not as numerous as the permit holders on the U.S. mainland, HMS fisheries are active in these two areas and several of the communities benefit from those activities. Due to the number of HMS permit holders in these areas, future HMS actions should consider developing community profiles for Christiansted, St. Croix, as well as San Juan, Guaynabo, Aguadilla, Mayaguez, and/or Vega Baja, Puerto Rico. While NMFS may have community profiles describing these areas, an HMS-specific community profile should be developed for these towns to best determine the impact of changes to HMS-related regulations.

## 3.7 International Trade and Fish Processing

Several regional fishery management organizations (RFMOs) including ICCAT have taken steps to improve collection of international trade data to further international conservation policy for management of HMS. While RFMOs cannot re-create information about stock production based on trade data, this information can be used provisionally to estimate landings related to these fisheries, and to identify potential compliance problems with certain ICCAT management measures. United States participation in HMS related international trade programs, as well as a review of trade activity, is discussed in this section. This section also includes a review of the available information on the processing industry for Atlantic HMS species.

### 3.7.1 Overview of International Trade for Atlantic HMS

#### 3.7.1.1 Trade Monitoring

The United States collects general trade monitoring data through the U.S. Bureau of Customs and Border Protection (CBP; imports) and the U.S. Bureau of the Census (Census Bureau; exports and imports). These programs collect data on the amount and value of imports and exports categorized under the Harmonized Tariff Schedule (HTS). Many HMS have distinct HTS codes, and some species are further subdivided by product (*e.g.* fresh or frozen, fillets, steaks, etc.). NMFS provides Census Bureau trade data for marine fish products online for the public at http://www.st.nmfs.gov/st1/trade/index.html. Some species, such as sharks, are grouped together, which can limit the value of these data for fisheries management when species specific information is needed. These data are further limited since the ocean area of origin for each product is not distinguished. For example, the HTS code for Atlantic, Pacific, and even Indian Ocean bigeye tuna is the same.

Trade data for Atlantic HMS are of more use as a conservation tool when they indicate the flag of the harvesting vessel, the ocean of origin, and the species for each transaction. Under the authority of ATCA and the Magnuson-Stevens Act, NMFS collects this information while monitoring international trade of bluefin tuna, swordfish, southern bluefin tuna, and frozen bigeye tuna. These programs implement ICCAT recommendations and support rebuilding efforts by collecting data necessary to identify nations and individuals that may be fishing in a manner that diminishes the effectiveness of ICCAT fishery conservation and management measures. Copies of all trade monitoring documents associated with these programs may be found on the NMFS HMS Management Division webpage at http://www.nmfs.noaa.gov/sfa/hms/. These and several other trade monitoring programs established by NMFS for HMS are described in further detail below.

#### 3.7.1.2 Bluefin Tuna Statistical Document

The trade of bluefin tuna is tracked internationally as a result of the ICCAT recommendation to implement the Bluefin Statistical Document (BSD) program

(Recommendation 92-01). Japan's support for the program, as a major importer of bluefin tuna, is partially responsible for the success of this program. In the United States, each bluefin tuna is tagged when documented, and for all nations, the BSD travels with each shipment until the final point of destination. This document is used to track both imports and exports of bluefin tuna by ICCAT and other participating nations. If bluefin tuna are exported from, or imported to, the United States, the document is submitted to NMFS as part of the monitoring program. Since 1997, NMFS has also received CBP data (derived from Entry Form 7501) on imports of fresh and frozen bluefin tuna and swordfish on a monthly basis. Comparison of these data with BSD data allows NMFS to identify shipments without BSDs in order to obtain missing data and enforce dealer reporting requirements. In 2003, ICCAT updated the BSD program to include the collection of farming related information on the BSD. In 2005, NMFS added a re-export certificate to the program and expanded it to include southern bluefin tuna as well. Data collected under the BSD program are discussed in Sections 3.7.2 and 3.7.3 addressing U.S. exports and imports of HMS.

#### 3.7.1.3 Swordfish Certificate of Eligibility and Statistical Document

The U.S. Swordfish Certificate of Eligibility (COE) has tracked U.S. imports of swordfish since it was implemented in 1999. In 2005, this program was replaced by a swordfish statistical document (SD) program similar to the BSD program described above. The swordfish SD program is based on a 2001 ICCAT recommendation (01-22), and incorporates all of the prior functions of the COE, including the following: ensuring that all imported swordfish are greater than the minimum size of 14.9 kg (33 lb) dw, identifying the flag of the harvesting vessel, and indicating ocean area of origin. Similar to the BSD program, CBP data on swordfish imports is also used to obtain missing data and identify dealers that are not following the required reporting procedures. With implementation of the swordfish SD program, the swordfish COE is longer in effect.

#### 3.7.1.4 Bigeye Tuna Statistical Document

Like the two previous trade monitoring programs, the bigeye tuna SD program is used to track movement of internationally traded bigeye tuna to its final destination. ICCAT recommended the implementation of a bigeye tuna SD program in 2001 (01-21). The initial program was implemented in 2005 along with the swordfish SD, and applies only to frozen bigeye tuna. It may be expanded to cover fresh product in the future. Other RFMOs including the Inter-American Tropical Tuna Commission and the Indian Ocean Tuna Commission have also adopted frozen bigeye SD programs.

#### 3.7.1.5 Yellowfin Tuna Form 370

Since the late 1970s, NOAA Form 370 has been used to document imports of yellowfin tuna and other species of tuna for the purpose of protecting dolphins in the Eastern Tropical Pacific Ocean. Form 370 is filed with other documents necessary for entry of yellowfin tuna into the United States. The form is *not* required for fresh tuna, animal food, or canned petfood made from tuna.

#### 3.7.1.6 Billfish Certificate of Eligibility

The Billfish Certificate of Eligibility is used to ensure that any billfish being imported or sold in the United States (outside of the Pacific states) is not of Atlantic origin. In the Pacific states, billfish involved in trade are presumed to be of Pacific origin. Any statement that contains the specified information is sufficient to meet the certificate of eligibility documentation requirements; it is not necessary to use the form available from NMFS or to submit the form to NMFS upon final disposition of the billfish.

### 3.7.2 U.S. Exports of HMS

"Exports" may include merchandise of both domestic and foreign origin. The Census Bureau defines exports of "domestic" merchandise to include commodities which are grown, produced, or manufactured in the United States (*e.g.*, fish caught by U.S. fishermen). For statistical purposes, domestic exports also include commodities of foreign origin which have been altered in the United States from the form in which they were imported, or which have been enhanced in value by further manufacture in the United States. The value of an export is the f.a.s. (free alongside ship) value defined as the value at the port of export based on a transaction price including inland freight, insurance, and other charges incurred in placing the merchandise alongside the carrier. It excludes the cost of loading the merchandise, freight, insurance, and other charges or transportation costs beyond the port of exportation.

#### 3.7.2.1 Atlantic and Pacific Bluefin Tuna Exports

As discussed in the previous section, NMFS collects detailed export data on Atlantic and Pacific bluefin tuna through the BSD program. Table 3.80 gives bluefin tuna export data for exports from the United States. Recent decreases in Atlantic BFT exports since 1999 could in part be a result of the growing U.S. market for high-quality fresh bluefin tuna meat. In 2003 – 2004, exports also could have been impacted by a reduction in U.S. landings. BFT re-exports are discussed separately in Section 3.7.3.1 and shown in Table 3.7.

**Table 3.80 United States exports of Atlantic and Pacific bluefin tuna, 1999-2004.** Sources: NMFS BSD Program, NERO, and Census Bureau.

| | | | | | | **Value of U.S. Exports (Census Bureau, $ million)** |
|---|---|---|---|---|---|---|
| 1999 | 876.0 | 735.6 | 95.7 | 831.3 | 1,183 | 9.37 |
| 2000 | 903.9 | 758.0 | 76.0 | 834.0 | 1,044 | 11.20 |
| 2001 | 987.0 | 812.3 | 67.0 | 879.0 | 1,020 | 10.70 |
| 2002 | 964.0 | 730.4 | 0.1 | 730.5 | 922 | 10.74 |
| 2003 | 756.9 | 572.2 | 2.1 | 574.3 | 998 | 11.36 |
| 2004 | 495.0 | 247.2 | 0.0 | 247.2 | 370 | 4.50 |

Note: most exports of Pacific BFT were in round (whole) form, although some exports were of dressed and gilled/gutted fish; Atlantic exports included whole, dressed, and product forms (dw); data are preliminary and subject to change.

### 3.7.2.2 Other Tuna Exports

Export data for other tunas is gathered by the Census Bureau, and includes trade data for albacore, yellowfin, bigeye, and skipjack tuna from all ocean areas of origin combined. Behind bluefin tuna, albacore tuna accounts for the next most valuable tuna export from the United States (Table 3.81). Comparing the last five years, the amount and value of exported albacore was greatest for the year 2004. In general, the amount and value of albacore exports appears to be on the rise. During the time period covered by this table, the annual amount and value of frozen exports exceeded fresh exports for every year.

**Table 3.81 Amount and value of U.S. exports of albacore tuna from all ocean areas, 1999-2004 (Census Bureau data) and U.S. landings of North Atlantic albacore tuna (*2005 U.S. National Report to ICCAT*).**

| | | **Exports** (from all ocean areas) | | | | | |
|---|---|---|---|---|---|---|---|
| | | | | | | **Total for all Exports** | |
| | | | | | | | **US$ (million)** |
| 1999 | 317 | 517 | 1.01 | 2,743 | 5.52 | 3,260 | 6.54 |
| 2000 | 407 | 263 | 0.78 | 2,747 | 6.04 | 3,010 | 6.83 |
| 2001 | 324 | 1,542 | 3.62 | 4,609 | 9.83 | 6,151 | 13.45 |
| 2002 | 488 | 680 | 1.50 | 4,483 | 8.28 | 5,163 | 9.78 |
| 2003 | 448 | 894 | 1.86 | 9,731 | 18.85 | 10,624 | 20.71 |
| 2004 | 636 | 1,360 | 3.28 | 10,737 | 24.11 | 12,097 | 27.38 |

Note: Landings may be calculated on a calendar or fishing year basis; exports may be in whole (ww) or product weight (dw); data are preliminary and subject to change.

Table 3.82 and Table 3.83 show U.S. Atlantic landings and U.S. exports from all ocean areas combined for yellowfin and skipjack tuna, respectively. Yellowfin exports were greater and more valuable than exports for skipjack or bigeye tuna (Table 3.84), although yellowfin tuna exports decreased markedly in 2004. Export of fresh yellowfin product exceeded the value of frozen yellowfin product for all years except 2001. Fresh product exports were highest in 2002 and 2003. The amount and value of exported fresh and frozen skipjack tuna has varied over the six year period covered in Table 3.83, without any discernable trends. Exports and landings of skipjack in 1999 far exceeded values for the following five years.

**Table 3.82 Amount and value of U.S. exports of yellowfin tuna from all ocean areas, 1999-2004 (Census Bureau data) and U.S. landings of Atlantic yellowfin tuna (*2005 U.S. National Report to ICCAT).***

| | | **Exports** (from all ocean areas) | | | | | |
|---|---|---|---|---|---|---|---|
| | | | | | | **Total for all Exports** | |
| | | | | | | | **US$ (million)** |
| 1999 | 7569 | 947 | 2.09 | 390 | .84 | 1337 | 2.93 |
| 2000 | 7051 | 412 | 1.12 | 406 | .76 | 819 | 1.89 |
| 2001 | 6703 | 290 | .71 | 834 | 1.45 | 1124 | 2.17 |
| 2002 | 5653 | 1612 | 2.37 | 420 | .81 | 2033 | 3.19 |
| 2003 | 7701 | 1792 | 2.93 | 176 | .68 | 1968 | 3.62 |
| 2004 | 6421 | 306 | 1.54 | 242 | .31 | 549 | 1.86 |

Note: Landings may be calculated on a calendar or fishing year basis; exports may be in whole (ww) or product weight (dw); data are preliminary and subject to change.

**Table 3.83 Amount and value of U.S. exports of skipjack tuna from all ocean areas, 1999-2004 (Census Bureau data) and U.S. landings of West Atlantic skipjack tuna (*2005 U.S. National Report to ICCAT*).**

| | | **ports** (from all ocean areas) | | | | | |
|---|---|---|---|---|---|---|---|
| | | | | | | **Total for all Exports** | |
| | | | | | | | **US$ (million)** |
| 1999 | 152 | 88 | .20 | 1092 | .89 | 1,181 | 1.10 |
| 2000 | 44 | 7 | .01 | 83 | .05 | 91 | .06 |
| 2001 | 69 | 82 | .15 | 34 | .04 | 117 | .20 |
| 2002 | 66 | 66 | .17 | 11 | .01 | 77 | .18 |
| 2003 | 77 | 81 | .22 | 0 | 0 | 81 | .22 |
| 2004 | 61 | 55 | .30 | 140 | .78 | 196 | .48 |

Note: Landings data may have been ported on either a fishing year or calendar year basis; exports may be in whole (ww) or product weight (dw); data are preliminary and subject to change.

Bigeye tuna exports and Atlantic landings are given in Table 3.84. No data were available for bigeye tuna exports in 2001, and prior to 2001 bigeye exports were included in the category of unspecified tuna. Annually, bigeye tuna exports include more fresh than frozen product, and have increased gradually from 2002 to 2004.

**Table 3.84 Amount and value of U.S. exports of bigeye tuna from all ocean areas, 1999-2004 (Census Bureau data) and U.S. landings of Atlantic bigeye tuna (*2005 U.S. National Report to ICCAT*).**

| | | **rts** (from all ocean areas) | | | | | |
|---|---|---|---|---|---|---|---|
| | | | | | | **Total for all Exports** | |
| | | | | | | | **US$ (million)** |
| 2002 | 600 | 95 | .22 | 8 | .01 | 104 | .24 |
| 2003 | 480 | 255 | .47 | 40 | .08 | 295 | .56 |
| 2004 | 418 | 361 | 1.40 | 48 | .10 | 410 | 1.51 |

NOTE: Landings data may have been reported on either a fishing year or calendar year basis; exports may be in whole (ww) or product weight (dw); data are preliminary and subject to change.

#### 3.7.2.3 Shark Exports

Export data for sharks is gathered by the Census Bureau, and includes trade data for sharks from any ocean area of origin. Shark exports are not categorized down to the species level with the exception of dogfish, and are not identified by specific product code other than fresh or frozen meat and fins. Due to the popular trade in shark fins and their high relative value compared to shark meat, a specific HTS code was assigned to shark fins in 1998. It should be noted that there is no tracking of other shark products besides meat and fins. Therefore, NMFS cannot track trade in shark leather, oil, or shark cartilage products.

Table 3.85 indicates the magnitude and value of shark exports by the United States from 1999 – 2004. The reduction in shark fin exports from 2001 to 2002 and 2003 is of particular note, as is the increase in the unit value of shark fins during this time period. Decreases in shark fin trade are expected to be the result of the Shark Finning Prohibition Act, which was enacted in December of 2000 and implemented by final rule in February 2002.

**Table 3.85 Amount and value of U.S. shark product exports from 1999-2004.** Source: Census Bureau.

| | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | | | | | **US$ (million)** |
| 1999 | 106 | .91 | 8.54 | 270 | .48 | 1.80 | 155 | .46 | 2.97 | 532 | 1.86 |
| 2000 | 365 | 3.51 | 9.62 | 430 | .78 | 1.82 | 345 | .81 | 2.35 | 1140 | 5.10 |
| 2001 | 335 | 3.16 | 9.44 | 332 | .54 | 1.64 | 634 | 2.34 | 3.69 | 1301 | 6.04 |
| 2002 | 123 | 3.46 | 28.00 | 968 | 1.47 | 1.52 | 982 | 2.34 | 2.38 | 2075 | 7.28 |
| 2003 | 45 | 4.03 | 87.79 | 837 | 1.31 | 1.57 | 592 | 1.34 | 2.28 | 1476 | 6.70 |
| 2004 | 63 | 3.02 | 47.53 | 536 | 1.18 | 2.21 | 472 | .98 | 2.09 | 1071 | 5.18 |

Note: Exports may be in whole (ww) or product weight (dw); data are preliminary and subject to change.

#### 3.7.2.4 Re-exports of Atlantic HMS

For purposes of international trade tracking of HMS, the term “re-export” refers to a product that has been entered for consumption into the United States and then exported to another country, with or without further processing in the United States (from 50 CFR Part 300, Subpart M, International trade documentation and tracking programs for HMS). For most HMS species, re-export activity is a small fraction of export activity and well below reference points of 1000 mt and/or one million dollars annually. Exceptions to this include fresh yellowfin tuna re-exports which were valued at $1.5 million in 2003 and fresh and frozen yellowfin valued at $1.1 million in 2002 (Census Bureau data). In 2004, dried shark fin re-exports reached a six year maximum value of $1.8 million (29 mt, down from 34 mt in 2003).

Bluefin tuna re-exports also reached a five year maximum in 2004 at 2,118 mt valued at $29.46 million (Census Bureau data), which exceeded the amount of bluefin exports for the year, for the first time in the history of the BSD program (K. Goldsmith, pers. com.). Further investigation into BSD program data found that the recent increases in bluefin re-exports reflects the growth of the Mexican farming/mariculture industry which exports product to the United States for re-export to Japan.

#### 3.7.2.5 Summary of Atlantic HMS Exports

Nationally, the value of HMS exports (from all ocean areas combined) is dominated by bluefin tuna, albacore tuna, and shark products. In 2003, fresh and frozen products of these three species accounted for 14,873 mt dw or 1.3 percent of the 1,120,354 mt dw of fresh and frozen seafood products exported from the United States, as indicated in *Fisheries of the United States, 2004*. The value of these HMS products accounted for $40.77 million, out of a national total of $2.8 billion.

Data reflecting international trade of HMS species harvested from all ocean areas are of limited value for describing trade of HMS harvested from the Atlantic Ocean. For example, Atlantic landings of albacore tuna (commercial and recreational) for 2003 were reported in the *2004 U.S. National Report to ICCAT* as 448 mt (Table 3.81). National trade data show that over 10,000 mt of albacore were exported, which indicates that the majority of albacore exports were Pacific Ocean product. Trade tracking programs such as the bluefin tuna, swordfish, and bigeye tuna statistical document programs are much more useful for describing the international disposition of Atlantic HMS.

### 3.7.3 U.S. Imports of Atlantic HMS

All import shipments must be reported to the U.S. Bureau of Customs and Border Protection. “General” imports are reported when a commodity enters the country, and "consumption" imports consist of entries into the United States for immediate consumption combined with withdrawals from CBP bonded warehouses. “Consumption” import data reflect the actual entry of commodities originating outside the United States into U.S. channels of consumption. As discussed previously, CBP data for certain products are provided to NMFS for use in implementing statistical document programs. U.S. Census Bureau import data are used by NMFS as well.

#### 3.7.3.1 Bluefin Tuna Imports

United States imports and re-exports of bluefin tuna for 1999 through 2004, as reported through both CBP and BSD program data, are shown in Table 3.86. The difference in import numbers between the CBP and BSD data may be explained by a lack of knowledge and compliance with the BSD program by importers, especially those on the Pacific coast.

The rise in popularity of sashimi in the United States has generated increased imports of bluefin tuna, and dealers are reporting an expanded domestic market for both locally-caught and imported raw tuna. As discussed previously, the large amount of re-exports in the last several years resulted from the increase in importation of farmed bluefin from Mexico and re-exportation to Japan.

**Table 3.86 Imports of Atlantic and Pacific bluefin tuna into the United States: 1999-2004.** Sources: NMFS BSD program and CBP data.

| | | | **U.S. CBP Data** | |
|---|---|---|---|---|
| | | | | **VALUE (US$ million)** |
| 1999 | 411.9 | 16.6 | 558.6 | 3.02 |
| 2000 | 361.9 | 99.3 | 453.4 | 7.67 |
| 2001 | 512.9 | 7.0 | 532.3 | 8.21 |
| 2002 | 529.3 | 94.1 | 605.0 | 9.75 |
| 2003 | 649.9 | 691.0 | 780.3 | 11.67 |
| 2004 | 823.4 | 684.8 | 886.1 | 15.25 |

Note: Most imports of BFT were in dressed form, and some were round and gilled/gutted fish, fillets or belly meat (dw); data are preliminary and subject to change. Southern bluefin tuna trade was included in figures for Atlantic and Pacific bluefin tuna trade prior to 2002.

### 3.7.3.2 Other Tuna Imports

Since January 2001, CBP has been collecting species specific import information for bigeye tuna (grouped to include all ocean areas). Previously, bigeye tuna had been included under general tuna imports. The total amount and value of bigeye tuna imports have been gradually increasing over the last four years, as shown in Table 3.87.

**Table 3.87 Imports of bigeye tuna into the United States from all ocean areas combined: 2001-2004.** Source: Census Bureau data.

| | | | | | Total for all Imports | |
|---|---|---|---|---|---|---|
| | | | | | | US$ (million) |
| 2001 | 4684 | 25.70 | 135 | .32 | 4,820 | 26.02 |
| 2002 | 6312 | 39.84 | 319 | .70 | 6,632 | 40.55 |
| 2003 | 7312 | 51.01 | 560 | 1.48 | 7,872 | 52.49 |
| 2004 | 6752 | 49.10 | 1175 | 2.62 | 7928 | 51.73 |

Note: Imports may be whole weight (ww) or product weight (dw); data are preliminary and subject to change.

Annual yellowfin tuna imports into the United States for all ocean areas combined are given in Table 3.88. As indicated by the data in this section, yellowfin tuna are imported in the greatest quantity of all fresh and frozen tuna products. The annual value of yellowfin imports has increased gradually from 1999 – 2004. The total annual amount of product imported has remained fairly consistent, with a slight dip in 2000.

**Table 3.88 Imports of yellowfin tuna into the United States from all ocean areas combined: 1999-2004.** Source: Census Bureau data.

| | | | | | Total for all Imports | |
|---|---|---|---|---|---|---|
| | | | | | | US$ (million) |
| 1999 | 11,756 | 63.04 | 9411 | 24.90 | 21,168 | 87.94 |
| 2000 | 13,153 | 70.27 | 3290 | 18.73 | 16,443 | 89.00 |
| 2001 | 15,563 | 85.50 | 3967 | 23.45 | 19,530 | 108.95 |
| 2002 | 15,966 | 95.22 | 4619 | 29.31 | 20,585 | 124.53 |
| 2003 | 15,299 | 94.03 | 5579 | 39.67 | 20,878 | 133.71 |
| 2004 | 15,624 | 99.41 | 5833 | 35.35 | 21,457 | 134.96 |

NOTE: Imports may be whole weight (ww) or product weight (dw); data are preliminary and subject to change.

The amount of fresh albacore imports from all ocean areas have been fairly consistent since 2001 while imports of frozen product have decreased dramatically over the last six years, with the greatest reduction occurring between 2001 and 2002 (Table 3.89). In 1999, albacore imports were valued at $144 million while in 2004 the value dropped to approximately $15 million. (Products in airtight containers are not included in these data.)

**Table 3.89 Imports of albacore tuna into the United States from all ocean areas combined: 1999-2004.**
Source: Census Bureau data.

| | | | | | Total for all Imports | |
|---|---|---|---|---|---|---|
| | | | | | | US$ (million) |
| 1999 | 1776 | 5.39 | 63,284 | 139.50 | 65,060 | 144.89 |
| 2000 | 1843 | 6.42 | 51,001 | 127.33 | 52,845 | 133.76 |
| 2001 | 1107 | 3.85 | 40,428 | 105.58 | 41,536 | 109.43 |
| 2002 | 1296 | 4.81 | 11,903 | 24.49 | 13,200 | 29.31 |
| 2003 | 1062 | 4.11 | 12,569 | 25.90 | 13,632 | 30.02 |
| 2004 | 1004 | 3.12 | 4943 | 11.67 | 5947 | 14.80 |

Note: Imports may be whole weight (ww) or product weight (dw); data are preliminary and subject to change.

Skipjack tuna imports into the United States are comprised mainly of frozen product (Table 3.90). Like albacore tuna, the amount and value of skipjack imports have also decreased dramatically since 1999. The amount of product imported fell from over 8,000 mt dw in 1999 to 112 mt dw in 2004. Likewise, the value of these products during this time period fell from $6.3 million to $0.27 million.

**Table 3.90 Imports of skipjack tuna from all ocean areas combined into the United States: 1999-2004.**

### 3.7.3.3 Swordfish Imports

Table 3.91 summarizes swordfish import data collected by NMFS' Swordfish Import Monitoring Program for the 2004 calendar year. According to these data, most swordfish imports were Pacific Ocean product. For Atlantic product, the most imports came from Brazil (48 percent), followed by Canada (22 percent) and Uruguay (16 percent). CBP data located at the bottom of the table reflect a larger amount of imports than reported by the import monitoring program, and may be used by NMFS staff to follow up with importers, collect statistical documents that have not been submitted, and enforce dealer reporting requirements.

**Table 3.91 Swordfish import data for the 2004 calendar year collected under the NMFS Swordfish Import Monitoring Program.**

| | Ocean Area of Origin | | | | TOTAL (mt dw) |

COE Data as of 8/18/05

Table 3.92 indicates the amount and value of swordfish product imports by the United States from 1999 – 2004, as recorded by the U.S. Census Bureau, for all ocean areas combined. The amount of each product imported per year and annual totals for product and value were fairly consistent for the time period covered, although the data show a slight decrease in 2004.

**Table 3.92 Imported swordfish products by year: 1999-2004.** Source: Census Bureau data.

| Year | | | | | | Total for all Imports | |
|---|---|---|---|---|---|---|---|
| | | Other | | | | | US$ (million) |
| 1999 | 81 | 8595 | 4377 | 401 | 386 | 13,842 | 71.70 |
| 2000 | 161 | 8626 | 4833 | 524 | 167 | 14,314 | 85.57 |
| 2001 | 71 | 8982 | 3814 | 710 | 119 | 13,697 | 81.89 |

| 2004 | 157 | 6568 | 3261 | 387 | 351 | 10,726 | 70.95 |

NOTE: Imports may be whole weight (ww) or product weight (dw); data are preliminary and subject to change.

#### 3.7.3.4 Shark Imports

Similar to tuna imports other than bluefin tuna and frozen bigeye tuna, NMFS does not require importers to collect and submit information regarding the ocean area of catch. Shark imports are also not categorized by species, and lack specific product information on imported shark meat such as the proportion of fillets, steaks, or loins. The condition of shark fin imports; *e.g.*, wet, dried, or further processed products such as canned shark fin soup, is also not collected. There is no longer a separate tariff code for shark leather, so its trade is not tracked by CBP or Census Bureau data.

The United States may be an important transshipment port for shark fins, which may be imported wet, processed and then exported dried. It is also probable that U.S.-caught shark fins are exported to Hong Kong or Singapore for processing, and then imported back into the United States for consumption by urban-dwelling Asian Americans (Rose, 1996).

Table 3.93 summarizes Census Bureau data on shark imports for 1999 through 2004. Imports of fresh shark products and shark fins have decreased significantly since 1999. The 2004 ICCAT recommendation addressing the practice of shark finning may result in a further reduction of imports in the near future. Over the last 5 years, the overall annual amount and value of shark imports decreased fairly consistently year after year to equal approximately half the 1999 amount and value in 2003, with a slight increase in each product category in 2004.

**Table 3.93 U.S. imports of shark products from all ocean areas combined: 1999-2004.** Source: Census Bureau data.

| | | | | | | | Total For All Imports | |
|---|---|---|---|---|---|---|---|---|
| | | | | | | | | US$ (million) |
| 1999 | 59 | 2.10 | 1,095 | 2.03 | 105 | .62 | 1,260 | 4.76 |
| 2000 | 66 | 2.35 | 1,066 | 1.85 | 90 | .57 | 1,222 | 4.79 |
| 2001 | 50 | 1.08 | 913 | 1.38 | 123 | 1.78 | 1,087 | 4.25 |
| 2002 | 39 | 1.02 | 797 | 1.24 | 91 | 1.09 | 928 | 3.35 |
| 2003 | 11 | 0.01 | 515 | 0.72 | 100 | 0.99 | 626 | 1.82 |
| 2004 | 14 | 0.34 | 650 | 1.00 | 156 | 2.35 | 821 | 3.70 |

NOTE: Imports may be whole weight (ww) or product weight (dw); data are preliminary and subject to change.

#### 3.7.3.5 Summary of U.S. Imports of Atlantic HMS

The import data in this section show that many HMS species are part of a valuable import market. As discussed previously regarding exports, most data documenting imports include products harvested from many ocean areas, not just the Atlantic Ocean. However, the statistical document programs for bluefin tuna, swordfish, and frozen bigeye tuna provide information specifically about product harvested from the Atlantic Ocean and imported into the United States.

In 2004, the U.S. domestic market for swordfish supported a domestic fishery of 2,896 mt round weight worth $14.64 million (Pritchard 2005) and an active import market of 10,726 mt dw valued at $70.95 million (Table 3.13). Despite recent increases in the U.S. quota of North Atlantic swordfish (consistent with ICCAT rebuilding programs), swordfish from the Pacific and Indian Oceans are expected to continue to supply the lucrative U.S. swordfish market during the near future.

### 3.7.4 The Use of Trade Data for Conservation Purposes

Trade data has been used in a number of ways to support international management of HMS. When appropriate, the SCRS uses trade data on bluefin tuna, swordfish, bigeye tuna, and yellowfin tuna that are submitted to ICCAT as an indication of landings trends. These data can then be used to augment estimates of fishing mortality rates (F) of these species, which improves scientific stock assessments. In addition, these data can be used to assist in assessing compliance with ICCAT recommendations and identify those countries whose fishing practices diminish the effectiveness of ICCAT conservation and management measures. On numerous occasions, ICCAT has adopted recommendations to address the lack of compliance with management programs for the bluefin tuna, bigeye tuna, and North and South Atlantic swordfish fisheries by ICCAT members. Penalties for non-compliance or fishing in a manner that diminishes the effectiveness of ICCAT conservation measures may include catch limit reductions and, if necessary, trade restrictive measures.

For example, an analysis of vessel sighting and Japanese BSD data led to the 1996 determination that fishing vessels from the countries of Panama, Honduras, and Belize were fishing in a manner that diminished the effectiveness of the bluefin tuna rebuilding program, and resulted in a 1996 ICCAT recommendation for sanctions against the import of bluefin tuna from these countries (Table 3.94). In 1999, ICCAT recommended this trade restriction on Panama be lifted as a result of the Government of Panama's efforts to substantially reduce fishing vessel activities deemed inconsistent with ICCAT measures. In 2001, Honduras became a member of ICCAT, and based on this change in status and Honduras' significant efforts to control its fleet and address ICCAT concerns, ICCAT recommended lifting trade sanctions for bluefin tuna. The bluefin sanction for Belize was lifted by ICCAT in 2002.

In another example, import data from 1997–1999 revealed significant Atlantic bluefin tuna exports from Equatorial Guinea despite the fact that a zero catch limit was in effect for that country. The government of Equatorial Guinea had not responded to ICCAT inquiries and had reported no bluefin tuna catch data to ICCAT, and as a result ICCAT recommended trade restrictions as a penalty for non-compliance. Based on information regarding improved compliance presented by Equatorial Guinea at the 2004 ICCAT meeting, specifically, that Equatorial Guinea had canceled licenses and flags of large-scale longline vessels previously participating in IUU tuna fishing in the Convention area and guaranteed compliance with ICCAT conservation and management measures, the trade sanction was lifted by ICCAT.

As indicated in Table 3.94, most of the trade sanctions recommended by ICCAT since 1996 have been lifted. In fact, only trade sanctions for Bolivia and Georgia remain in effect. Thus, the imposition of trade sanctions seems to be an effective measure for ensuring that countries involved in international trade operate in a manner consistent with ICCAT recommended conservation programs. As illustrated above, the data obtained by monitoring international trade in HMS is instrumental in the development of ICCAT trade restrictions. Current discussions at ICCAT include expanding the statistical document program to a catch documentation scheme, which may better assist in preventing IUU fishing.

**Table 3.94 Summary and current status of ICCAT recommended trade sanctions for bluefin tuna, swordfish, and bigeye tuna implemented by the United States.**

### 3.7.5 Overview of the Processing Industry for Atlantic HMS

Understanding the harvesting and processing sectors is essential when analyzing world trade in highly migratory fish species. The processing related entities that depend on Atlantic HMS are as diverse as the species and products themselves. Processing techniques range from the simple dressing and icing of swordfish at sea, to elaborate grading and processing schemes for bluefin tuna, to processing shark fins. Like all other seafood, HMS are perishable and may pose health hazards if not handled properly. Products range from those having a long shelf-life, such as swordfish, to highly perishable species like yellowfin tuna. Improperly handled yellowfin tuna can produce histamine, swordfish and sharks may contain high levels of mercury, and shark meat requires careful handling due to the high concentrations of urea in the body of the shark. Processing companies are aware of these characteristics and their costs of doing business vary accordingly to protect consumers. The Food and Drug Administration (FDA) works closely with NOAA Office of Law Enforcement to monitor incoming shipments of seafood, including highly migratory species.

FDA's Seafood Hazard Analysis Critical Control Point (HACCP) program implemented regulations that require processors of fish and fishery products to operate preventive control systems to ensure human food safety. Among other things, processors must effectively maintain the safety of their products, systematically monitor the operation of critical control points to ensure that they are working as they should, and keep records of the results of that monitoring. Processors must also develop written HACCP plans that describe the details and operation of their HACCP systems. Each processor may tailor its HACCP system to meet its own circumstances. The best way for FDA to determine whether a processor is effectively operating a HACCP system is by inspecting the processor. Federal review of monitoring and other records generated by the HACCP system is a critical component of an inspection because it allows the inspector to match records against the practices and conditions being observed in the plant and it discourages fraud. NMFS works closely with the FDA, in support of the HACCP program.

Just as HACCP plans vary between processors, transportation of the seafood to market also varies widely from the direct domestic sale of some shark or swordfish meat by a fisherman to a restaurant (carried by truck) to the quick, and sometimes complicated, export of bluefin tuna from fisherman to dealer to broker to the Japanese auction (carried by a commercial airline carrier). Frozen swordfish and tunas are often brought to the United States by overseas shipping companies and sharks and other products may be exported from the United States, processed overseas, and imported in a final product form.

It is unknown how many U.S. companies depend on HMS fisheries, other than the registered dealers who buy fish directly from U.S. fishermen and/or who import bluefin tuna or swordfish. The proportion of those companies that depend solely on Atlantic HMS versus those that handle other seafood and/or products is also unknown. This section provides a summary of the most recent trade data that NMFS has analyzed, as well as a brief description of the processing and trade industries employed in transitioning Atlantic HMS from the ocean to the plate.

#### 3.7.5.1 Processing and Wholesale Sectors

NMFS has limited quantitative information on the processing sector, including the amount of HMS products sold in processed forms. In addition, knowledge regarding the utilization of Atlantic HMS is largely limited to the major or most valuable product forms, such as export quality bluefin tuna.

Much of the processing of export-quality Atlantic bluefin tuna occurs onboard the vessel harvesting the fish, which serves to maximize fish quality. Bluefin are gutted and bled, and protected from the heat and sunlight by immersion in ice or an icy brine. Upon landing, bluefin are immediately graded and prepared for export to Japan's fresh fish market. The fish are either refrigerated or exported immediately in insulated crates or "coffins" filled with ice or icepacks.

Other Atlantic tunas, especially bigeye tuna, are frequently shipped fresh to Japan in dressed form. Swordfish are sold fresh and frozen in dressed form and as processed products (*e.g.*, steaks and fillets). The utilization of sharks is also not well known since trade statistics frequently do not indicate product forms such as skins and leather, jaws, fishmeal and fertilizer, liver oil, and cartilage (Rose, 1996). Domestically-landed sandbar and blacktip shark meat may be sold to supermarkets and processors of frozen fish products. NMFS continues to work with industry to collect information specific to U.S. and foreign processing of Atlantic HMS to better track markets, conserve stocks, and manage sustainable fisheries.

The U.S. processing and wholesale sectors are dependent upon both U.S. and international HMS fisheries. Individuals involved in these businesses buy the seafood, cut it into pieces that transform it into a consumer product, and then sell it to restaurants or retail outlets. Employment varies widely among processing firms. Often employment is seasonal unless the firms also process imported seafood or a wide range of domestic seafood. The majority of firms handles other types of seafood and is not solely dependent on HMS. Other participants in the commercial trade sector include brokers, freight forwarders, and carriers (primarily commercial airlines, trucking, and shipping companies). Swordfish, tunas, and sharks are important commodities on world markets, generating significant amounts in export earnings in recent years.

NMFS has recently observed that many seafood dealers that buy and sell highly migratory species and other seafood products have expanded their operations into internet-powered trading platforms specifically designed to meet the needs of other seafood professionals. Through these platforms, interested parties can conduct very detailed negotiations with many trading partners simultaneously. Buyers and sellers can bargain over all relevant elements of a market transaction (not just price) and can specify the product needed to buy or sell in detail, using seafood-specific terminology. The platforms are purportedly very easy to use because they mimic the pattern of traditional negotiations in the seafood industry. NMFS expects that the use of the internet will continue to change the way HMS trade occurs in the future.

## 3.8 Bycatch, Incidental Catch, and Protected Species

Bycatch in commercial and recreational fisheries has become an important issue for the fishing industry, resource managers, scientists, and the public. Bycatch can result in death or injury to the discarded fish, and it is essential that this component of total fishing-related mortality be incorporated into fish stock assessments and evaluation of management measures. Bycatch precludes other more productive uses of fishery resources and decreases the efficiency of fishing operations. Although not all discarded fish die, bycatch can become a large source of mortality, which can slow the rebuilding of overfished stocks. Bycatch imposes direct and indirect costs on fishing operations by increasing sorting time and decreasing the amount of gear available to catch target species. Incidental catch concerns also apply to populations of marine mammals, sea turtles, seabirds, and other components of ecosystems which may be protected under other applicable laws and for which there are no commercial or recreational uses but for which existence values may be high.

In 1998, NMFS developed a national bycatch plan, *Managing the Nation's Bycatch* (NMFS, 1998), which includes programs, activities, and recommendations for Federally managed fisheries. The national goal of the Agency's bycatch plan activities is to implement conservation and management measures for living marine resources that will minimize, to the extent practicable, bycatch and the mortality of bycatch that cannot be avoided. Inherent in this goal is the need to avoid bycatch, rather than create new ways to utilize bycatch. The plan also established a definition of bycatch as fishery discards, retained incidental catch, and unobserved mortalities resulting from a direct encounter with fishing gear.

### 3.8.1 Bycatch Reduction and the Magnuson-Stevens Act

The Magnuson-Stevens Act defines bycatch as fish which are harvested in a fishery, but which are not sold or kept for personal use, and includes economic and regulatory discards. Fish is defined as finfish, mollusks, crustaceans, and all other forms of marine animal and plant life other than marine mammals and birds. Seabirds and marine mammals are therefore not considered bycatch under the MSA but are examined as incidental catch. Bycatch does not include fish released alive under a recreational catch-and-release fishery management program.

National Standard 9 of the Magnuson-Stevens Act requires that fishery conservation and management measures shall, to the extent practicable, minimize bycatch and minimize the mortality of bycatch that cannot be avoided. In many fisheries, it is not practicable to eliminate all bycatch and bycatch mortality. Some relevant examples of fish caught in Atlantic HMS fisheries that are included as bycatch or incidental catch are marlin, undersized swordfish and bluefin tuna caught and released by commercial fishing gear; undersized swordfish and tunas in recreational hook and line fisheries; species for which there is little or no market such as blue sharks; and species caught and released in excess of a bag limit.

There are benefits associated with the reduction of bycatch, including the reduction of uncertainty concerning total fishing-related mortality, which improves the ability to assess the status of stocks, to determine the appropriate relevant controls, and to ensure that overfishing levels are not exceeded. It is also important to consider the bycatch of HMS in fisheries that target other species as a source of mortality for HMS and to work with fishery constituents and resource manager partners on an effective bycatch strategy to maintain sustainable fisheries. This strategy may include a combination of management measures in the domestic fishery, and if appropriate, multi-lateral measures recommended by international bodies such as ICCAT or coordination with Regional Fishery Management Councils or States. The bycatch in each fishery is summarized annually in the SAFE report for Atlantic HMS fisheries. The effectiveness of the bycatch reduction measures is evaluated based on this summary.

A number of options are currently employed (*) or available for bycatch reduction in Atlantic HMS fisheries. These include but are not limited to:

Commercial

1. *Gear Modifications (including hook and bait types)
2. *Circle Hooks
3. *Time/Area Closures
4. Performance Standards
5. *Education/Outreach
6. *Effort Reductions (*i.e.*, Limited Access)
7. Full Retention of Catch
8. *Use of De-hooking Devices (mortality reduction only)

Recreational

1. Use of Circle Hooks (mortality reduction only)
2. Use of De-hooking Devices (mortality reduction only)
3. Full Retention of Catch
4. *Formal Voluntary or Mandatory Catch-and-Release Program for all Fish or Certain Species
5. Time/Area Closures

There are probably no fisheries in which there is zero bycatch because none of the currently legal fishing gears are perfectly selective for the target of each fishing operation (with the possible exception of the swordfish/tuna harpoon fishery and proposed speargun fishery). Therefore, to totally eliminate bycatch of all non-target species in Atlantic HMS fisheries would be impractical. The goal then is to minimize the amount of bycatch to the extent practicable and minimize the mortality of species caught as bycatch.

### 3.8.2 Standardized Reporting of Bycatch

Section 303(a)(11) of the Magnuson-Stevens Act requires that a fishery management plan establish a standardized reporting methodology to assess the amount and type of bycatch occurring in the fishery. In 2004, NMFS published a report entitled *"Evaluating Bycatch: A National Approach to Standardized Bycatch Monitoring Programs,"* which described the current status of and guidelines for bycatch monitoring programs (NMFS, 2004a). The data collection and analyses that are used to estimate bycatch in a fishery constitute the "standardized bycatch reporting methodology" (SBRM) for that fishery (NMFS, 2004a). Appendix 5 of the report specifies the protocols for SBRMs established by NMFS throughout the country.

As part of the Agency's National Bycatch Strategy, NMFS established a National Working Group on Bycatch (NWGB) to develop a national approach to standardized bycatch reporting methodologies and monitoring programs. This work is to be the basis for regional teams, established in the National Bycatch Strategy, to make fishery-specific recommendations.

The NWGB reviewed regional issues related to fisheries and bycatch and discussed advantages and disadvantages of various methods for estimating bycatch including: (1) fishery-independent surveys; (2) self-reporting through logbooks, trip reports, dealer reports, port sampling, and recreational surveys; (3) at-sea observation, including observers, digital video cameras, digital observers, and alternative platform and remote monitoring; and (4) stranding networks. All of the methods may contribute to useful bycatch estimation programs, but at-sea observation (observers or electronic monitoring) provides the best mechanism to obtain reliable and accurate bycatch estimates for many fisheries. Often, observer programs also will be the most cost-effective of these alternatives. However, observers are not always the most cost-effective or practicable method for assessing bycatch (NMFS, 2004a).

The effectiveness of any SBRM depends on its ability to generate estimates of the type and quantity of bycatch that are both precise and accurate enough to meet the conservation and management needs of a fishery. The National Bycatch Report (NMFS, 2004a) contains an in-depth examination of the issues of precision and accuracy in estimating bycatch. Accuracy refers to the closeness between the estimated value and the (unknown) true value that the statistic was intended to measure. Precision refers to how closely multiple measurements of the same statistic cluster to one another when obtained under the same protocol. The more precise an estimate is the tighter the cluster. The precision of an estimate is often expressed in terms of the coefficient of variation (CV) defined as the standard error of the estimator divided by the estimate. The lower the CV, the more precise the estimate is considered to be. A precise estimate is not necessarily an accurate estimate. The National Bycatch Report (NMFS, 2004a) contains an extensive discussion of how precision relates to sampling and to assessments.

The other important aspect of obtaining bycatch estimates that are useful for management purposes is accuracy. Accuracy is the difference in the mean of the sample and the true value of that property in the sampled universe (NMFS, 2004a). In other words, accuracy refers to how correct the estimate is. Efficient allocation of sampling effort within a stratified survey design improves the precision of the estimate of overall discard rates (Rago *et al.*, 2005). Accuracy of sample estimates can be evaluated by comparing performance measures (e.g., landings, trip duration) between vessels with and without observers present. While there are differences between the terms accuracy and bias they have been used interchangeably. A "biased" estimate is inaccurate while an "accurate" estimate is unbiased (Rago *et al.*, 2005).

The NWGB recommended that at-sea sampling designs should be formulated to achieve precision goals for the least amount of observation effort, while also striving to increase accuracy (NMFS, 2004a). This can be accomplished through random sample selection, developing appropriate sampling strata and sampling allocation procedures, and by implementing appropriate tests for bias. Sampling programs will be driven by the precision and accuracy required by managers to address management needs for estimating management quantities such as allowable catches through a stock assessment, for evaluating bycatch relative to a management standard such as allowable take, and for developing mitigation mechanisms.

The recommended precision goals for estimates of bycatch are defined in terms of the coefficient of variation (CV) of each estimate. For marine mammals and other protected species, including seabirds and sea turtles, the recommended precision goal is a 20 to 30 percent CV for estimates of interactions for each species/stock taken by a fishery. For fishery resources, excluding protected species, caught as bycatch in a fishery, the recommended precision goal is a 20 to 30 percent CV for estimates of total discards (aggregated over all species) for the fishery; or if total catch cannot be divided into discards and retained catch, then the goal is a 20 to 30 percent CV for estimates of total catch (NMFS, 2004a). The report also states that attainment of these goals may not be possible or practical in all fisheries and should be evaluated on a case-by-case basis.

The CV of an estimate can be reduced and the precision increased by increasing sample size. In the case of observer programs, this would entail increasing the number of trips or gear deployments observed. Increasing the number of trips observed increases both the cost in terms of funding, but also the logistical complexities and safety concerns. However, the improvements in precision will decline at a decreasing rate as sample size is increased to a point where it will not be cost-effective to increase sample size any further. This concept is illustrated in Figure 1 of the National Bycatch Report (NMFS, 2004a). As a result of this statistical relationship, fishery managers select observer coverage levels that should achieve the desired or required balance between precision of bycatch estimates and cost.

While the relationship between precision and sample size is relatively well known (NMFS, 2004), the relationship between sample size and accuracy is not reliable. Observer programs strive to achieve samples that are representative of both fishing effort and catches. Representativeness of the sample is critical not only for obtaining accurate (*i.e.*, unbiased) estimates of bycatch, but also for collecting information about factors that may be important for mitigating bycatch. Bias may be introduced at several levels: when vessels are selected for coverage, when hauls are selected for sampling, or when only a portion of the haul can be sampled (NMFS, 2004a).

Rago *et al.*, (2005) examined potential sources of bias in commercial fisheries of the Northeast Atlantic by comparing measures of performance for vessels with and without observers. Bias can arise if the vessels with observers onboard consistently catch more or less than other vessels, if trip durations change, or if vessels fish in different areas. Average catches (pounds landed) for observed and total trips compared favorably and the expected differences of the stratum specific means and standard deviations for both kept weight and trip duration was near zero (Rago *et al.*, 2005). Although mean trip duration was slightly longer on observed trips, the difference was not significantly different from zero. The spatial distribution of trips matched well based on a comparison of VMS data with observed trips (Murawski *et al.*, in press; as cited by Rago *et al.*, 2005). The authors concluded that the level of precision in discard ratios as a whole was high and that there was little evidence of bias. The results of this study indicate that bias may not be as large an issue in self-reported data as has been suggested by Babcock *et al.*

(2003), but additional analyses would need to be conducted to determine the applicability to HMS fisheries.

A simplistic approach in trying to get more accurate bycatch estimates is to increase observer coverage. A report by Babcock *et al.* (2003) suggests that relatively high percentages of observer coverage are necessary to adequately address potential bias in bycatch estimates from observer programs. However, the examples cited by Babcock *et al.* (2003) as successful in reducing bias through high observer coverage levels are fisheries comprised of relatively few vessels compared to many other fisheries, including the Atlantic HMS fisheries. Their examples are not representative of the issues facing most observer programs and fishery managers, who must work with limited resources to cover large and diverse fisheries. It is also incorrect to assume that simply increasing observer coverage ensures accuracy of the estimates (Rago *et al.*, 2005). Bias due to unrepresentative sampling may not be reduced by increasing sample size due to logistical constraints, such as if certain classes of vessels cannot accommodate observers. Increasing sample size may only result in a larger, but still biased, sample.

Although the precision goals for estimating bycatch are important factors in determining observer coverage levels, other factors are also considered when determining actual coverage levels. These may result in lower or higher levels of coverage than that required to achieve the precision goals for bycatch estimates. Factors that may justify lower coverage levels include lack of adequate funding; incremental coverage costs that are disproportionately high compared to benefits; and logistical consideration such as lack of adequate accommodations on a vessel, unsafe conditions, and lack of cooperation by fishermen (NMFS, 2004a).

Factors that may justify higher coverage levels include incremental coverage benefits that are disproportionately high compared to costs and other management focused objectives for observer programs. The latter include total catch monitoring, in-season management of total catch or bycatch, monitoring bycatch by species, monitoring compliance with fishing regulations, monitoring requirements associated with the granting of Experimental Fishery Permits, or monitoring the effectiveness of gear modifications or fishing strategies to reduce bycatch. In some cases, management may require one or even two observers to be deployed on every fishing trip. Increased levels of coverage may also be desirable to minimize bias associated with monitoring "rare" events with particularly significant consequences (such as takes of protected species), or to encourage the introduction of new "standard operating procedures" for the industry that decrease bycatch or increase the ease with which bias can be monitored (NMFS, 2004a).

NMFS utilizes self-reported logbook data (Fisheries Logbook System or FLS, and the supplemental discard report form in the reef fish/snapper-grouper/king and Spanish mackerel/shark logbook program), at-sea observer data, and survey data (recreational fishery dockside intercept and telephone surveys) to produce bycatch estimates in HMS fisheries. These data are collected with respect to fishing gear type (see Section 3.8.2). The number and location of discarded fish are recorded, as is the disposition of the fish (*i.e.*, released alive vs. released dead). Post-release mortality of HMS can be accounted for in stock assessments to the extent that the data allow.

The fishery logbook systems in place are mandatory programs, and it is expected that the reporting rates are generally high (Garrison, 2005). Due to the management focus on HMS fisheries, there has been close monitoring of reporting rates, and observed trips can be directly linked to reported effort. In general, the gear characteristics and amount of observed effort is consistent with reported effort. However, under-reporting is possible, which can lead to a negative bias in bycatch estimates. Cramer (2000) compared dead discards of undersized swordfish, sailfish, white and blue marlin, and pelagic sharks from HMS logbook and POP data in the U.S. Atlantic pelagic longline fishery. Cramer (2000) provided the ratio of catch estimated from the POP data divided by the reported catch in the HMS logbooks. The ratio indicated the amount of underreporting for each species in a given area. However, the data analyzed by Cramer (2000), was based on J-hook data from 1997 – 1999 and that gear is illegal now. In some instances, logbooks are used to provide effort information against which bycatch rates obtained from observers is multiplied to estimate bycatch. In other sectors/fisheries, self-reporting provides the primary method of reporting bycatch because of limited funding, priorities, etc.

The following section provides a review of the bycatch reporting methodologies for all HMS fisheries currently in place. Future adjustments may be implemented based on evaluation of the results of studies developed as part of the HMS Bycatch Reduction Implementation Plan, or as needed due to changing conditions in the fisheries. In addition, NMFS is in the process of developing a National Bycatch Report which may provide additional insight and guidance on areas to be addressed for each fishery. Further analyses of bycatch in the various HMS fisheries may be conducted as time, resources and priorities allow.

#### 3.8.2.1 U.S. Atlantic Pelagic Longline Fishery

NMFS utilizes both self-reported data (mandatory logbooks for all vessels) and observer data to monitor bycatch in the pelagic longline fishery. The observer program has been in place since 1992 to document finfish bycatch, characterize fishery behavior, and quantify interactions with protected species (Beerkircher *et al.*, 2002). The program is mandatory for those vessels selected and all vessels with directed and indirect swordfish permits are selected. The program had a target coverage level of five percent of the U.S. fleet within the North Atlantic (waters north of $5^{o}$ N. latitude), as was agreed to by the United States at ICCAT. Actual coverage levels achieved from 1992 – 2003 ranged from two to nine percent depending on quarter and year. Observer coverage was 100 percent for vessels participating in the NED experimental fishery during 2001 – 2003. Overall observer coverage in 2003 was 11.5 percent of the total sets made, including the NED experiment. The program began requiring an eight percent coverage rate due to the requirements of the 2004 Biological Opinion for Atlantic Pelagic Longline Fishery for HMS. Observer coverage in 2004 ranged from 6.2 – 9.0 percent per quarter. Since 1992, data collection priorities have been to collect catch and effort data of the U.S. Atlantic pelagic longline fleet on highly migratory fish species, although information is also collected on bycatch of protected species.

Fishery observer effort is allocated among eleven large geographic areas and calendar quarter based upon the historical fishing range of the fleet (Walsh and Garrison, 2006). The target annual coverage is eight percent of the total reported sets, and observer coverage is randomly allocated based upon reported fishing effort during the previous fishing year/quarter/statistical reporting area (Beerkircher *et al.*, 2002). Bycatch rates of protected species (catch per 1,000 hooks) are quantified based upon observer data by year, fishing area, and quarter (Garrison, 2005). The estimated bycatch rate is then multiplied by the fishing effort (number of hooks) in each area and quarter reported to the FLS program to obtain estimates of total interactions for each species of marine mammal and sea turtle (Garrison, 2005).

#### 3.8.2.2 Purse Seine Fishery

Vessels operating in the bluefin tuna purse seine fishery submit either Vessel Trip Reports (NERO) or HMS logbooks (Southeast) based on the type of Federal permits they hold in addition to their HMS permit. Observers were placed on purse seine vessels operating in this fishery in 1996 and 2001 in order to monitor groundfish bycatch in closed areas in the Northwest Atlantic (B. McHale, pers. comm., 2005). The purse seine fishery was observed to have very little bycatch of groundfish or other species of fish and no protected species interactions. As a result, observer coverage has not been used recently to document bycatch or validate logbook reports.

#### 3.8.2.3 Shark Bottom Longline Fishery

Vessels participating in the bottom longline fishery for sharks are required to submit snapper/grouper/reef fish/shark logbooks to report their catch and effort, including bycatch species. All vessels having Shark Limited Access Permits are required to report. The Commercial Shark Fishery Observer Program (CSFOP) has monitored the shark bottom longline fishery since 1994. The program has been mandatory for vessels selected to carry observers beginning in 2002. Prior to that, it was a voluntary program relying on cooperating vessels/captains to take observers. From 2002 – 2005, the objective of the vessel selection was to achieve a representative five percent level of coverage of the total fishing effort in each fishing area (North Atlantic, South Atlantic, and Gulf of Mexico) and during each fishing season of that year (Smith *et al*., 2006). Beginning in 2006, target coverage level will be 3.9 percent of the total fishing effort. This level is estimated to attain a sample size needed to provide estimates of sea turtle, smalltooth sawfish, or marine mammal interactions with an expected CV of 0.3 (Carlson, unpubl., as cited in Smith *et al*., 2006)

Effective August 1, 2001, selected Federal permit holders that report on the Gulf of Mexico reef fish, South Atlantic snapper-grouper, king and Spanish mackerel, and shark fisheries logbook must report all species and quantities of discarded (alive and dead) sea turtles, marine mammals, birds, and finfish on a supplemental discard form. A randomly selected sample of 20 percent of the vessels with active permits in the above fisheries is selected each year. The selection process is stratified across geographic area (Gulf of Mexico and South Atlantic), gear (handline, longline, troll, gillnet, and trap), and number of fishing trips (ten or less trips and more than 11 trips). Of the 3,359 vessels with Federal permits in these fisheries in 2003, a total of 452 vessels were selected to report. Of the 3,517 vessels with Federal permits in the fisheries in 2004, 428 were selected to report. Shark fishermen can use the pelagic longline logbook or the northeast vessel trip reports depending on the permits held by the vessel. If they use either the PLL logbook or VTR, they need to report all of the catch and effort, as well as all the bycatch or incidental catch.

#### 3.8.2.4 Shark Gillnet Fishery

Vessels participating in the gillnet fishery for sharks are required to submit logbooks to report their catch and effort, including bycatch species. An observer program for the directed shark gillnet fishery has been in place from 1993 – 1995 and from 1998 to the present. The objectives of this program are to obtain estimates of catch and bycatch and bycatch mortality rates of protected species, juvenile sharks, and other fish species. Catch and bycatch estimates are produced to meet the mandates of the Atlantic Large Whale Take Reduction Plan and the October 2003 Biological Opinion.

During right whale calving season (15 November to 31 March), 100 percent observer coverage is required for shark gillnet vessels operating from West Palm Beach, FL, to Sebastian Inlet, FL. Outside right whale calving season, observer coverage is equal to that which would obtain a sample size needed to provide estimates of sea turtle or marine mammal interactions with an expected CV of 0.3 (in 2003, this was 33.8 percent of the total trips) (Carlson and Baremore, 2002). On June 21, 2005, NMFS proposed modifying the time and areas where 100 percent observer coverage is required during right whale calving season (70 FR 35894). NMFS has proposed that, from November 15 to April 15, 100 percent observer coverage would be required for gillnet vessels fishing between the SC/GA border and 29$^{o}$ 00 N. Gillnet vessels fishing between 29$^{o}$ 00 N and 26$^{o}$ 46.5 N would be required to have 100 percent observer coverage from December 1 to March 31.

Starting in 2005, a pilot observer program was begun to include all vessels that have an active directed shark permit and fish with sink gillnet gear (Carlson and Bethea, 2006). These vessels were not subject to observer coverage because they were either targeting non-highly migratory species or were not fishing gillnets in a drift or strike fashion. These vessels were selected for observer coverage in an effort to determine their impact on finetooth shark landings and their overall impact on shark resources when not targeting sharks. One of the alternatives to reduce mortality of finetooth sharks in this document would thereby increase observer coverage to these vessels with directed shark permits that report landing sharks with gillnet.

#### 3.8.2.5 Commercial Handgear Fishery

The commercial handgear fishery includes vessels using handline, harpoon, rod and reel, or bandit gear to fish for HMS. NMFS has the authority to use observers to collect bycatch information from commercial vessels fishing for tunas. Many of these vessels are already required to complete Federal and/or state logbooks (*e.g.*, the NMFS Northeast Region Vessel Trip Report (VTR) Program), in which they are required to report all fishing information, including that for HMS and bycatch. NMFS is currently evaluating various alternatives to increase fishery data collection of vessels fishing for HMS with handgear, such as selecting additional HMS permitted vessels to report in logbooks or to be selected for observer coverage, and is investigating alternatives for electronic reporting. Therefore, no estimates of bycatch are available at this time. Bycatch and bycatch mortality are considered to be low due to the nature of the gear but this should be validated in the future.

#### 3.8.2.6 Recreational Handgear Fishery

NMFS collects recreational catch-and-release data from dockside surveys (the Large Pelagics Survey and the Marine Recreational Fishery Statistics Survey) for the rod and reel fishery and uses these data to estimate total landings and discards of bycatch or incidental catch. Statistical problems associated with small sample size remain an obstacle to estimating bycatch reliably in the rod and reel fishery. CVs can be high for many HMS (rare event species in the MRFSS) and the LPS does not cover all times/geographic areas for non-bluefin tuna species. New survey methodologies are being developed, however, especially for the Charter/Headboat sector of the rod and reel fishery, which should help to address some of the problems in estimating bycatch for this fishery. In addition, selecting recreational vessels for voluntary logbook reporting may be an option for collecting bycatch information for this sector of the HMS fishery.

NMFS has the authority to use observers to voluntarily collect bycatch information from vessels with HMS Charter/Headboat or Angling category permits. Many of the charter/headboat vessels are required to complete Federal and/or state logbooks (*e.g.*, the NMFS Northeast Region Vessel Trip Report (VTR) Program), in which they are required to report all fishing information, including that for HMS and bycatch. NMFS is currently evaluating various alternatives to increase logbook coverage of vessels fishing for HMS, such as selecting additional HMS vessels to report in logbooks or be selected for observer coverage, and is investigating alternatives for electronic reporting.

The National Academy of Sciences assembled a committee to review current marine recreational fishing surveys at the request of NMFS (NAS, 2006). The committee was tasked with developing recommendations for improvements to current surveys and to recommend the implementation of possible alternative approaches. The committee's final report was published in April 2006, and NMFS is in the process of evaluating the recommendations. At the present time, no other alternative approach is available.

### 3.8.3 Bycatch Reduction in HMS Fisheries

The NMFS HMS bycatch reduction program includes an evaluation of current data collection programs, implementation of bycatch reduction measures such as gear modifications and time/area closures, and continued support of data collection and research relating to bycatch (Table 3.107). Additional details on bycatch and bycatch reduction measures can be found in Section 3.5 of the Fishery Management Plan for Atlantic Tunas, Swordfish and Sharks (NMFS, 1999), in Regulatory Amendment 1 to the 1999 FMP (NMFS, 2000), in Regulatory Adjustment 2 to the 1999 FMP (NMFS, 2002), and in Amendment 1 to the 1999 FMP (NMFS, 2003a). In addition, an HMS Bycatch Reduction Implementation Plan was developed in late 2003 which identify priority issues to be addressed in the following areas: 1) monitoring, 2) research, 3) management, and 4) education/outreach. Individual activities in each of these areas were identified and new activities may be added or removed as they are addressed or identified.

## 3.9 HMS Permits and Tournaments

This section provides updates for the number of permits that were issued in conjunction with HMS fishing activities as of February 2006. Furthermore, Section 3.9.6, Atlantic HMS Tournaments, provides a comprehensive synthesis of recreational fishing tournaments and their role in the context of HMS management.

NMFS' HMS Management Division continues to monitor capacity in HMS fisheries. Updated permit numbers for HMS fisheries as of April 2005, are included in Table 3.95 through Table 3.101. These tables have been updated since the Draft Consolidated HMS FMP, which listed numbers of permits as of April 2005. The overall number of limited access permits for Atlantic swordfish, tunas, and sharks increased from 1,128 to 1,131 (Table 3.95) between October 2005 and February 2006, however, these numbers are subject to change based upon on-going permit renewal or expiration. The overall number of tuna permits increased in all categories between October 2005 and February 2006 (Table 3.96). The HMS Angling Permit category went into effect on March 1, 2003 (67 FR 77434, December 18, 2003), and there has been a significant increase in Angling category permits over the past few years (Table 3.96). The number of tuna dealer permits increased from 364 (April 20, 2005) to 416 (February 1, 2006) (Table 3.99).

**Table 3.95 Distribution of Shark, Swordfish, and Tuna longline Limited Access Permits Between 2001 and 2006. Data for 2001-2005 are as of October 1 for each year.**

### 3.9.1 Upgrading and Safety Issues

When the limited access program was implemented, NMFS included upgrading restrictions that were the same as those implemented by the New England Fishery Management Council (NEFMC) and Mid-Atlantic Fishery Management Council (MAFMC) in order to help minimize the number of regulations for fishermen in those areas. These regulations restrict vessels from any increase over ten percent length overall (LOA), ten percent gross or net tonnage, and 20 percent horsepower. NMFS continues to receive comments that these vessel upgrading restrictions are not appropriate for longline fisheries, may inhibit full utilization of the domestic swordfish quota, are not the preferred vessel characteristics to limit overcapitalization, and have caused safety at sea concerns. In developing the current upgrading restrictions, hold capacity was identified by constituents as a vessel characteristic that would not impact safety at sea and would meet the objective of addressing overcapitalization in HMS commercial fisheries. NMFS did not implement hold capacity as a measure to limit vessel upgrading in 1999 due to the lack of standard measurements of vessel hold capacity as well as the lack of consistent collection of this information for HMS commercial vessels as part of existing vessel registration systems. NMFS has considered other possible options including: eliminating upgrading restrictions; limiting hold capacity instead of, or in addition to, the current restrictions; allowing a greater percentage increase; and creating vessel categories. NMFS heard similar comments as those listed above from the Advisory Panel (AP) in February of 2004. NMFS is considering these options, and, as with any potential changes in the permitting system, will allow for adequate public comment during the rulemaking process before making any changes to the regulations.

### 3.9.2 Atlantic Tunas Permits

The number of Atlantic Tunas permit holders by category is listed in Table 3.96. The number of permits in the Longline, General, and Charter/Headboat (CHB) categories increased between 2004 and April 2005. In previous years, CHB vessels fishing for HMS only needed a CHB permit if they were fishing for Atlantic tunas.

**Table 3.96 The number of Atlantic tuna permit holders in each category as of October 2001 through 2005. Permit numbers for 2006 are as of February 1, 2006. The actual number of 2006 permit holders in each category is subject to change as individuals renew or allow their permits to expire.**

| | | | | | | **2006** |

| CHB** | 3,260 | 3,659 | 4,167 | 3,881 | 3,963 | 4,173 |
| | | | | | | **34,501** |

* HMS Angling permit became effective March 1, 2003 (67 FR 77434, December 18, 2003) and includes all HMS, not just tunas.
****** No longer a tuna-only permit, became a HMS CHB permit on March 1, 2003

In December 2002, NMFS published a final rule (67 FR 77434, December 18, 2002) that required the owner of each vessel used to fish recreationally for Atlantic HMS or on which Atlantic HMS are retained or possessed, to obtain an HMS Angling permit. Effective March 1, 2003, this permit replaced the Atlantic Tunas Angling category permit. It is discussed in greater detail in the HMS Angling Permit section.

### 3.9.3 HMS CHB Permits

In 2002, NMFS published a final rule (67 FR 77434, Dec. 18, 2002) expanding the HMS recreational permit from tuna only to include all HMS and define CHB operations. This established a requirement that owners of charterboats or headboats that are used to fish for, take, retain, or possess Atlantic tunas, sharks, swordfish, or billfish must obtain a HMS CHB permit. This permit replaced the Atlantic Tunas CHB permit. A vessel issued a HMS CHB permit for a fishing year will not be issued an HMS Angling permit or any Atlantic Tunas permit in any category for that same fishing year, regardless of a change in the vessel's ownership. The total number of CHB increased between April 2005 and February 2006.

**Table 3.97 CHB Permits by State as of February 1, 2006.**

### 3.9.6 HMS Angling Permit

Effective March 2003 (67 FR 77434, Dec. 18, 2002), the HMS Angling category permit allows all recreational anglers aboard permitted vessels to fish for HMS and is required to fish for, retain, or possess, including catch and release fishing, any federally regulated HMS. These species include: sharks, swordfish, white and blue marlin, sailfish, spearfish, and federally regulated Atlantic tunas (bluefin, yellowfin, bigeye, skipjack, and albacore). Atlantic HMS caught, retained, possessed, or landed by persons on board vessels with an HMS Angling permit may not be sold or transferred to any person for a commercial purpose. By definition, recreational landings of Atlantic HMS are those that cannot be marketed through commercial channels, therefore it is not possible to monitor anglers' catches through ex-vessel transactions as in the commercial fishery. Instead, NMFS conducts statistical sampling surveys of the recreational fisheries. These survey programs have been used for over a decade and include the Marine Recreational Fisheries Statistics Survey (MRFSS) and the Large Pelagic Survey (LPS). A vessel issued an HMS Angling permit for a fishing year shall not be issued an HMS Charter/ Headboat permit or an Atlantic Tunas permit in any category for that same fishing year, regardless of a change in the vessel's ownership.

### 3.9.4 Dealer Permits

Dealer permits are required for commercial receipt of Atlantic tuna, swordfish, and sharks, and are described in further detail in the 1999 Tunas, Swordfish, and Sharks FMP. Dealer permits are not limited access. Fishermen caught selling HMS to unpermitted dealers and persons without a dealer permit buying HMS from fishermen could be subject to enforcement action. Similarly, persons caught buying HMS from non-commercial fishermen could also be subject to enforcement action. All dealer permit holders are required to submit reports detailing the nature of their business. For swordfish and shark permit holders (including those who *only* import swordfish), dealers must submit bi-weekly dealer reports on all HMS they purchase. Tuna dealers must submit, within 24 hours of the receipt of a bluefin tuna, a landing report for each bluefin purchased from U.S. fishermen. Dealers must also submit bi-weekly reports that include additional information on tunas that they purchase. To facilitate quota monitoring "negative reports" for shark and swordfish are also required from dealers when no purchases are made (*i.e.*, NMFS can determine who has not purchased fish versus who has neglected to report). NMFS continues to automate and improve its permitting and dealer reporting systems and plans to make additional permit applications and renewals available online in the near future.

Starting July 1, 2005, dealers who import and/or export certain HMS species are required to obtain the NMFS HMS International Trade Permit (ITP) (69 FR 67268, November 17, 2004) (Table 3.100). The permit has been established to coordinate U.S. implementation of ICCAT and IATTC trade tracking recommendations. The HMS ITP is required for trade of bluefin tuna, southern bluefin tuna, swordfish, and frozen bigeye tuna. Reporting associated with the HMS ITP will include biweekly reports and submission of swordfish, bluefin tuna, southern bluefin tuna and bigeye tuna statistical documents. Atlantic tunas and swordfish dealer permits will no longer be required for international trade of these species, and will be necessary only for domestic transactions. Additionally, the Pacific Ocean bluefin tuna dealer permit will no longer be in effect.

**Table 3.98 Number of shark and swordfish dealer permits issued in each state or country as of October 2001-2005. Permits for 2006 are as of February 1, 2006. The actual number of permits per may change as permit holders move or sell their businesses.**

### 3.9.5 Exempted Fishing Permits (EFPs), Display Permits, Chartering Permits, and Scientific Research Permits (SRPs)

EFPs, display permits, and SRPs are requested and issued under the authority of the Magnuson-Stevens Act (16 U.S.C. 1801 et seq.) and/or the ATCA (16 U.S.C. 971 et seq.). EFPs are issued to individuals interested in being exempted from regulations for the purpose of conducting research or other fishing activities using private (non-NOAA) vessels, whereas an SRP would be issued to agency scientists who are using NOAA vessels as their research platform. Display permits are issued to individuals who are fishing for, catching, and then transporting HMS to certified aquariums for public display. Regulations at 50 CFR 600.745 and 50 CFR 635.32 govern scientific research activity, exempted fishing, and exempted educational activity with respect to Atlantic HMS. Amendment 1 to the Atlantic Tunas, Swordfish, and Sharks FMP implemented and created a separate display permitting system, which operates apart from the exempted fishing activities that are focusing on scientific research. However, the application process for display permits is similar to that required for EFPs and SRPs. The quota is 60 mt ww for all sharks collected under exempted fishing permits.

Issuance of EFPs, display permits, and SRPs may be necessary because possession of certain shark and billfish species are prohibited, possession of billfishes on board commercial fishing vessels is prohibited, the commercial fisheries for bluefin tuna, swordfish and large coastal sharks may be closed for extended periods during which collection of live animals and/or biological samples would otherwise be prohibited, or for other reasons. These EFPs, SRPs, and display permits would authorize collections of tunas, swordfish, billfishes, and sharks from Federal waters in the Atlantic Ocean and Gulf of Mexico for the purposes of scientific data collection and public display. In addition, NMFS regulations at 50 CFR 635.32 regarding implantation or attachment of archival tags in Atlantic HMS require prior authorization and a report on implantation activities.

In order to implement the chartering recommendations of ICCAT, NMFS recently published a rule on December 6, 2004 (69 FR 70396), requiring U.S. vessel owners with HMS permits to apply for and obtain a chartering permit before fishing under a chartering arrangement outside U.S. waters. These permits are issued in a similar manner as other EFPs. Under this final rule and consistent with the ICCAT recommendations, vessels issued a chartering permit are not authorized to use the quota or entitlement of the United States until the chartering permit expires or is terminated. This is because of the fact that under a chartering arrangement it is assumed that vessels have attained temporary authorization to harvest another ICCAT Contracting Parties' quota. Having a chartering permit does not obviate the need to obtain a fishing license, permits, or other authorizations issued by the chartering nation in order to fish in foreign waters, or obtain other authorizations such as a High Seas Fishing Compliance Act Permit, 50 CFR 300.10 et seq. Additionally, incidental takes of, or interactions with, protected resources are included against the Incidental Take Statement specified in any relevant Biological Opinions. A U.S. vessel shall not be authorized to fish under more than one chartering arrangement at the same time. NMFS will issue chartering permits only if it determines that the chartering arrangement is in conformance with ICCAT's conservation and management programs.

The number of EFPs, display permits, and SRPs issued from 2002 – 2006 by category and species are listed in Table 3.101. Year-end reports for permits issued for 2004 are required, and are expected to be submitted to NMFS in early 2005.

### 3.9.6 Atlantic HMS Tournaments

Fishing tournaments are an important component of HMS recreational fisheries. A tournament is defined in the HMS regulations as any fishing competition involving Atlantic HMS in which participants must register or otherwise enter or in which a prize or award is offered for catching or landing such fish. Since 1999, Federal regulations have required that each HMS tournament operator register their tournament with NMFS at least four weeks prior to the commencement of tournament fishing activities. Tournament operators may be selected for reporting and must submit tournament results to NMFS within seven days of the conclusion of the tournament.

Tournament registration and reporting is necessary because it provides an important source of information used to assess HMS fish stocks and to estimate the annual catch of Atlantic HMS. The information may be used by NMFS to plan for the assignment of tournament observers to assist in catch/effort data compilation and to obtain biological data and samples from landed fish (length/weight, stomach contents, injuries, parasites, hard and soft tissue samples for age determination, genetic and microconstituent analysis, spawning condition, fecundity, etc.). Additionally, with an accurate tournament database, NMFS may better assess the practicality of using tournaments for angler educational outreach efforts including distribution of written informational materials, notification of public hearings, and explanation of HMS regulations. HMS tournament registration and reporting information further allows NMFS, in the course of developing fishery management plans, to evaluate the social and economic impact of tournament angling in relation to other types of angling (*e.g*., commercial, non-tournament recreational) and the relative effect of tournament angling on populations of various regulated HMS. Finally, the information is essential for the U.S. to meet its reporting obligations to ICCAT.

When registering an HMS tournament, the following information is required to be submitted to the HMS Management Division in St. Petersburg, FL: (1) Tournament name; (2) tournament location; (3) name, address, phone number, fax number, and e-mail address of tournament operator; (4) fishing dates; and (5) HMS species for which points or prizes are awarded. If selected for reporting, operators must submit the following information to the SEFSC: (1) Tournament name; (2) tournament dates; (3) tournament location; (4) number of boats fishing; (5) hours fished; (6) recorder's name, phone number, and e-mail address; (7) the number of each species kept; (8) the number of each species lost; (9) the number of each species tagged and released; (10) the number of each species released without a tag; (11) the number of each species released dead; and, (12) the weight and length of all fish boated. This information is routinely collected during tournament operations to award prizes. Generally, 100 percent of all billfish tournaments are selected for reporting, as this information is critical to determining billfish landings. Tournament registration forms are available at: http://www.nmfs.noaa.gov/sfa/hms/linkpages/reporting_forms.htm.

The reasons for participation in fishing tournaments include, but are not limited to, competition, camaraderie, and the opportunity to win valuable prizes. A search on the Internet for fishing tournaments (December, 2004) indicated that many saltwater tournaments target HMS. It has been estimated that approximately 300 – 400 HMS fishing tournaments occur annually along the U.S. Atlantic coast, including the Gulf of Mexico and Caribbean (NMFS, 1999). These tournaments may range from smaller, club member-only events with as few as ten participating boats (40 – 60 anglers) to larger, statewide tournaments with 250 or more participating vessels (1,000 – 1,500 anglers). For the larger tournaments, corporate sponsorship from tackle manufactures, marinas, boat dealers, beverage distributors, resorts, publications, chambers of commerce, restaurants, and others are often involved.

Many HMS fishing tournaments, particularly those that target billfish, promote strict conservation principles in their rules. For example, significant numbers of blue marlin, white marlin, and sailfish tournaments are "release-only," utilizing observers, angler affidavits, polygraph tests, photographs, or video cameras to document the live release of marlins.

Minimum sizes for fish that are landed are often larger than state and Federal requirements. Also, some tournaments prohibit treble hooks and may require circle hooks on certain baits. Because tournament participants are often well-respected anglers (*i.e*. highliners), these conservation trends and ethics likely influence the general angling population in a positive manner.

For anglers in HMS tournaments, winning the prize money may not be the only motive for participation. Many HMS fishing tournaments support charitable organizations; an internet search revealed that some of the charities who have benefited from fishing tournaments include: the Cystic Fibrosis Foundation, Make-A-Wish Foundation, Sloan-Kettering Skin Cancer Center, Boy Scouts of America, Ducks Unlimited, The Boys and Girls Club, The Broadstreet Clinic, Core Sound Waterfowl Museum, Hope Mission Christian Ministries, Sertoma by the Bay (breast cancer research), Take A Kid Fishing, Capt. Bob Lewis Scholarship Fund, South Nassau Communities Hospital, South Texas Children's, T. H. Rogers School for Impaired Children's Home, The Billfish Foundation, and Kids In Distress.

Table 3.102 presents the number of registered HMS tournaments, by state, between 2001 and 2005. This table indicates that, in 2005, HMS fishing tournaments were conducted most frequently in Florida, Louisiana, Puerto Rico, North Carolina, Texas, New Jersey, Maryland, Georgia, New York, Virgin Islands, and South Carolina. By far, the largest number of registered HMS tournaments has consistently occurred in the state of Florida.

| Handgear - Recreational | Undersize target species<br>Non-target finfish | Category III | ITS, Terms & Conditions | Large Pelagic Survey (1992); MRFSS (1981) | Regulations vary by species, including minimum sizes, retention limits, landing form; BFT quotas |

### 3.9.7 Evaluation and Monitoring of Bycatch

The identification of bycatch in Atlantic HMS fisheries is the first step in reducing bycatch and bycatch mortality. The Magnuson-Stevens Act requires the amount and type of bycatch to be summarized in the annual SAFE reports. Bycatch reporting is addressed in Section 3.8.3. Additional species and fishery specific data have already been presented in Section 3.2.

Pelagic longline dead discards of swordfish, billfish, large coastal sharks and pelagic sharks are estimated using data from NMFS observer reports and pelagic logbook reports. Shark bottom longline and shark gillnet discards can be estimated using logbook data and observer reports as well. Shark gillnet discards have also been estimated using logbook data when observer coverage is equal to 100 percent.

NMFS has not estimated bycatch in the swordfish harpoon fishery. NMFS has limited historical observer data on harpooned swordfish from driftnet trips in which harpoons were sometimes used. Swordfish harpoon fishermen are required to submit pelagic logbooks and NMFS can examine those for their utility in estimating bycatch. NMFS has not estimated bycatch in the bluefin tuna harpoon fishery because these fishermen have not been selected to submit logbooks. NMFS has not estimated bycatch in the General category commercial rod and reel tuna fishery although anecdotal evidence indicates that some undersized bluefin tuna may be captured. Studies of post-release mortality are ongoing.

There is concern about the accuracy of discard estimates in the recreational rod and reel fishery for HMS due to the low number of observations by the LPS and the MRFSS. Recreational bycatch estimates (numbers of fish released alive and dead) are not currently available, except for bluefin tuna. For some species, encounters are considered rare events, which might result in bycatch estimates with considerable uncertainty. Due to improvements in survey methodology, increased numbers of intercepts (interviews with fishermen) have been collected since 2002. NMFS intends to develop bycatch estimates (live and dead discards) and estimates of uncertainty from the recreational fishery from the LPS. These data will be included in future SAFE reports. Bycatch estimates may also be examined by using tournament data for the recreational fishery.

### 3.9.8 Bycatch Mortality

#### 3.9.8.1 Introduction

The reduction of bycatch mortality is an important component of National Standard 9. Physical injuries may not be apparent to the fisherman who is quickly releasing a fish because there may be injuries associated with the stress of being hooked or caught in a net. Little is known about the mortality rates of many of the species managed under this FMP but there are some data for certain species. Information on bycatch mortality of these fish should continue to be collected, and in the future, could be used to estimate bycatch mortality in stock assessments.

NMFS submits annual data (Task I) to ICCAT on mortality estimates (dead discards). These data are included in the SAFE reports and National Reports to ICCAT to evaluate bycatch trends in HMS fisheries.

#### 3.9.8.2 Mortality by Fishery

*Pelagic Longline Fishery*

NMFS collects data on the disposition (released alive or dead) of bycatch species from logbooks submitted by fishermen in the pelagic longline fishery. Observer reports also include disposition of the catch as well as information on hook location, trailing gear and injury status of protected species interactions. These data are used to estimate post-release mortality of sea turtles and marine mammals based on guidelines for each (Angliss and DeMaster 1998, Ryder *et al*. 2006). See Section 3.4.1 for estimates of sea turtle and marine mammal bycatch estimates.

*Purse Seine Fishery*

NMFS has limited observer data on the bluefin tuna purse seine fishery. There are no recorded instances of non-tuna finfish, other than minimal numbers of blue sharks, caught in tuna purse seines. Anecdotal evidence indicates that if fish are discarded, they are easily released out of the net with minimal bycatch mortality.

*Bottom Longline Fishery*

The shark bottom longline fishery has relatively low observed bycatch rates. Historically, finfish bycatch has averaged approximately five percent in the bottom longline fishery. Observed protected species bycatch (sea turtles) has typically been much lower, less than 0.01 percent of the total observed catch. See Section 3.4.5.1 for more information. Disposition of discards is recorded by observers and can be used to estimate discard mortality.

*Shark Gillnet Fishery*

The shark gillnet fishery has relatively low observed bycatch rates. Finfish bycatch during the 2003 fishery ranged from 3.3 to 20.7 percent of the total catch. Observed protected species bycatch (sea turtles and marine mammals) was very low, less than 0.1 percent. See Section 3.4.5 for more information. Disposition of discards is recorded by observers and can be used to estimate discard mortality.

*Commercial Handgear Fishery*

Vessels targeting bluefin tuna with harpoon gear have not been selected for observer coverage since the deliberate fishing nature of the gear is such that bycatch is expected to be low. Therefore, there are no recorded instances of non-target finfish caught with harpoons and NMFS cannot quantify the bycatch of undersized bluefin tuna in this fishery. Bycatch in the swordfish harpoon fishery is virtually if not totally, non-existent. Since bycatch approaches zero in this fishery, it follows that bycatch mortality is near zero. Disposition of bycatch reported in logbooks is used to estimate mortality of bycatch in the hook and line handgear fisheries.

*Recreational Handgear Fishery*

The LPS collects data on disposition of bycatch (released alive or dead) in recreational HMS fisheries. Rod and reel discard estimates from Virginia to Maine during June through October can be monitored through the expansion of survey data derived from the LPS (dockside and telephone surveys). However, the actual numbers of fish discarded for many species are low. See Section 3.4.4 for more information.

Post-release mortality studies have been conducted on few HMS at this time. Immediate mortality in recreational hook and line-caught juvenile bluefin tuna can be high (29.2 percent) due to injuries or predation (Belle, 1997). This is thought to be a conservative estimate because scientific personnel in the study were professionally trained and had extensive experience in fish handling techniques designed to reduce mortality. Mortality often occurs ten minutes or longer after the fish is released under normal circumstances. Injuries may not be readily apparent to the angler and seemingly minor capture injuries may be related to substantial internal injuries. Forty percent of sampled tuna that died during that study did not have injuries that would be apparent to the angler in the boat. Skomal and Chase (1996) provided evidence that the stress of rod and reel angling did not cause immediate post-release mortality in larger bluefin tuna (50 to 150 kg). However, they did document metabolic and pH disturbances in bluefin tuna sampled off Cape Hatteras, NC. The physiological consequences of angling stress are poorly understood for several species of large pelagic fishes (Skomal and Chase, 1996).

A study by Graves *et al.* (2002), investigated short-term (five days) post-release mortality of Atlantic blue marlin using pop-up satellite tag technology. A total of nine recreationally-caught blue marlin were tagged and released during July and August of 1999. All hooks employed in the study were "J" hooks. The attached tags were programmed to detach from the fish after five days and to record direct temperature and inclination of the buoyant tag to determine if the fish were actively swimming after being released. After detachment, the tags floated to the surface and began transmitting recorded position, temperature and inclination data to satellites of the Argos™ system. Three different lines of evidence provided by the tags (movement, water temperature, and tag inclination) suggested that at least eight of the nine blue marlin survived for five days after being tagged and released. One of the tags did not transmit any data which precluded the derivation of a conclusion regarding the tagged marlin's survival.

The study was continued in 2003 to evaluate post release survival and habitat use of white marlin using pop-up satellite archival tags (PSATs) caught and released from four locations in the western North Atlantic recreational fishery (Horodysky and Graves, 2005). Forty-one tags were attached to white marlin caught using dead baits rigged on straight shank ("J") hooks (n = 21) or circle hooks (n = 20) offshore of the U.S. Mid-Atlantic, the Dominican Republic, Mexico, and Venezuela. Survival was significantly higher ($p<0.01$) for white marlin caught on circle hooks (100 percent) relative to those caught on straight-shank ("J") hooks (65 percent). These results, along with previous studies on circle hook performance, suggest that a change in hook type can significantly increase the survival of white marlin released from recreational fishing gear. Data from these short term deployments also suggest that white marlin strongly associate with warm, near surface waters. However, based on the frequency, persistence, and patterns of vertical movements, white marlin appear to direct a considerable proportion of foraging effort well below surface waters, a behavior that may account for relatively high catch rates of white marlin on some pelagic longline sets. NMFS continues to support studies on recreational post-release mortality and intends to account for this source of mortality when additional information becomes available.

#### 3.9.8.3 Code of Angling Ethics

NMFS developed a Code of Angling Ethics as part of implementing Executive Order 12962 – Recreational Fisheries. NMFS implemented a national plan to support, develop, and implement programs that were designed to enhance public awareness and understanding of marine conservation issues relevant to the wellbeing of fishery resources in the context of marine recreational fishing. This code is consistent with National Standard 9, minimizing bycatch and bycatch mortality, and is therefore reproduced below. These guidelines are discretionary, not mandatory, and are intended to inform the angling public of NMFS views regarding what constitutes ethical angling behavior. Part of the code covers catch-and-release fishing and is directed towards minimizing bycatch mortality.

**Code of Angling Ethics**

- Promotes, through education and practice, ethical behavior in the use of aquatic resources.
- Values and respects the aquatic environment and all living things in it.
- Avoids spilling, and never dumps any pollutants, such as gasoline and oil, into the aquatic environment.
- Disposes of all trash, including worn-out lines, leaders, and hooks, in appropriate containers, and helps to keep fishing sites litter-free.
- Takes all precautionary measures necessary to prevent the spread of exotic plants and animals, including live baitfish, into non-native habitats.
- Learns and obeys angling and boating regulations, and treats other anglers, boaters, and property owners with courtesy and respect.
- Respects property rights, and never trespasses on private lands or waters.
- Keeps no more fish than needed for consumption, and never wastefully discards fish that are retained.
- Practices conservation by carefully handling and releasing alive all fish that are unwanted or prohibited by regulation, as well as other animals that may become hooked or entangled accidentally.
- Uses tackle and techniques, which minimize harm to fish when engaging in "catch-and-release" angling.

### 3.9.9 Interactions of HMS Fishing Gears with Protected Species

This section examines the interaction between protected species and Atlantic HMS fisheries under consideration in this FMP. As a point of clarification, interactions are different than bycatch. Interactions take place between fishing gears and marine mammals, sea turtles, and seabirds while bycatch consists of discards of fish. Following a brief review of the three acts (Marine Mammal Protection Act, Endangered Species Act, and Migratory Bird Treaty Act) affecting protected species, the interactions between HMS gears and each species is examined. Additionally, the interaction of seabirds and longline fisheries are considered under the auspices of the United States "National Plan of Action for Reducing the Incidental Catch of Seabirds in Longline Fisheries" (NPOA – Seabirds).

#### 3.9.9.1 Interactions and the Marine Mammal Protection Act

The Marine Mammal Protection Act of 1972 as amended (MMPA) is one of the principal Federal statutes that guide marine mammal species protection and conservation policy. In the 1994 amendments, section 118 established the goal that the incidental mortality or serious injury of marine mammals occurring during the course of commercial fishing operations be reduced to insignificant levels approaching a zero mortality rate goal (ZMRG) and serious injury rate within seven years of enactment (*i.e*,. April 30, 2001). In addition, the amendments established a three-part strategy to govern interactions between marine mammals and commercial fishing operations. These include the preparation of marine mammal stock assessment reports, a registration and marine mammal mortality monitoring program for certain commercial fisheries (Category I and II), and the preparation and implementation of take reduction plans (TRP).

NMFS relies on both fishery-dependent and fishery-independent data to produce stock assessments for marine mammals in the Atlantic Ocean, Gulf of Mexico, and Caribbean Sea. Draft stock assessment reports are typically published around January and final reports are typically published in the Fall. Final 2005 stock assessment reports are available and can be obtained on the web at:
http://www.nmfs.noaa.gov/prot_res/PR2/Stock_Assessment_Program/sars.html

The following marine mammal species occur off the Atlantic and Gulf Coasts that are or could be of concern with respect to potential interactions with HMS fisheries.

| Common Name | Scientific Name |
|---|---|
| Atlantic spotted dolphin | *Stenella frontalis* |
| Blue whale | *Balaenoptera musculus* |
| Bottlenose dolphin | *Tursiops truncatus* |
| Common dolphin | *Delphinis delphis* |
| Fin whale | *Balaenoptera physalus* |
| Harbor porpoise | *Phocoena phocoena* |
| Humpback whale | *Megaptera novaeangliae* |
| Killer whale | *Orcinus orca* |
| Long-finned pilot whale | *Globicephela melas* |
| Minke whale | *Balaenoptera acutorostrata* |
| Northern bottlenose whale | *Hyperoodon ampullatus* |
| Northern right whale | *Eubalaena glacialis* |
| Pantropical spotted dolphin | *Stenella attenuata* |
| Pygmy sperm whale | *Kogia breviceps* |
| Risso's dolphin | *Grampus griseus* |
| Sei whale | *Balaenoptera borealis* |

| | |
|---|---|
| Short-beaked spinner dolphin | *Stenella clymene* |
| Short-finned pilot whale | *Globicephela macrorhynchus* |
| Sperm whale | *Physeter macrocephalus* |
| Spinner dolphin | *Stenella longirostris* |
| Striped dolphin | *Stenella coeruleoalba* |
| White-sided dolphin | *Lagenorhynchus acutus* |

Under MMPA requirements, NMFS produces an annual list of Fisheries (LOF) that classifies domestic commercial fisheries, by gear type, relative to their rates of incidental mortality or serious injury of marine mammals. The LOF includes three classifications:

1. Category I fisheries are those with frequent serious injury or mortality to marine mammals;
2. Category II fisheries are those with occasional serious injury or mortality; and
3. Category III fisheries are those with remote likelihood of serious injury or mortality to marine mammals.

The final 2005 MMPA LOF was published on January 4, 2004 (71 FR 247) and the draft 2006 MMPA LOF was published on April 24, 2006 (71 FR 20941). The Atlantic Ocean, Caribbean, and Gulf of Mexico large pelagic longline fishery is classified as Category I (frequent serious injuries and mortalities incidental to commercial fishing) and the southeastern Atlantic shark gillnet fishery is classified as Category II (occasional serious injuries and mortalities). The following Atlantic HMS fisheries are classified as Category III (remote likelihood or no known serious injuries or mortalities): Atlantic tuna purse seine; Gulf of Maine and Mid-Atlantic tuna, shark and swordfish, hook-and-line/harpoon; southeastern Mid-Atlantic and Gulf of Mexico shark bottom longline; and Mid-Atlantic, southeastern Atlantic, and Gulf of Mexico pelagic hook-and-line/harpoon fisheries. Commercial passenger fishing vessel (charter/headboat) fisheries are subject to Section 118 and are listed as a Category III fishery. Recreational vessels are not categorized since they are not considered commercial fishing vessels. For additional information on the fisheries categories and how fisheries are classified, see http://www.nmfs.noaa.gov/pr/interactions/lof/.

Fishermen participating in Category I or II fisheries are required to register under the MMPA and to accommodate an observer aboard their vessels if requested. Vessel owners or operators, or fishermen, in Category I, II, or III fisheries must report all incidental mortalities and serious injuries of marine mammals during the course of commercial fishing operations to NMFS. There are currently no regulations requiring recreational fishermen to report takes, nor are they authorized to have incidental takes (*i.e.*, they are illegal).

NMFS continues to investigate serious injuries to marine mammals as they are released from fishing gear. In April 1999, NMFS held a joint meeting of the three regional scientific review groups to further discuss the issue. NMFS is continuing to develop marine mammal serious injury guidelines and until these are published, NMFS will apply the criteria listed by the review groups to make determinations for specific fisheries. The current Biological Opinions for Atlantic HMS fisheries have resulted in a conclusion of no jeopardy for marine mammals.

However, a Pelagic Longline Take Reduction Team (PLTRT) was recently formed and first met on June 29-30, 2005. The PLTRT replaces the disbanded Atlantic Offshore Cetacean Take Reduction Team (AOCTRT). The PLTRT must develop a Take Reduction Plan (TRP) for pilot whales within 11 months. The Draft TRP has been transmitted to NMFS and will be published shortly. The 1999 HMS FMP implemented several of the recommendations of the AOCTRT including: 1) a requirement that vessels fishing for HMS move one nautical mile (nm) after an entanglement with protected species; 2) limiting the length of the mainline to 24 nm in the MAB from August 1, 1999 through November 30, 2000; 3) voluntary vessel operator education workshops for HMS pelagic longline vessels; 4) handling and release guidelines; and 5) limited access for swordfish, shark and tuna longline permits. A summary of the observed and estimated marine mammal interactions with the pelagic longline fishery is presented in Table 3.26 and Table 3.27 of Section 3.4.1.

#### 3.9.9.2 Interactions and the ESA

The Endangered Species Act of 1973 as amended (16 U.S.C. 1531 et seq.) provides for the conservation and recovery of endangered and threatened species of fish, wildlife, and plants. The listing of a species is based on the status of the species throughout its range or in a specific portion of its range in some instances. Threatened species are those likely to become endangered in the foreseeable future [16 U.S.C. §1532(20)] if no action is taken to stop the decline of the species. Endangered species are those in danger of becoming extinct throughout all or a significant portion of their range [16 U.S.C. §1532(20)]. Species can be listed as endangered without first being listed as threatened. The Secretary of Commerce, acting through NMFS, is authorized to list marine and anadromous fish species, marine mammals (except for walrus and sea otter), marine reptiles (such as sea turtles), and marine plants. The Secretary of the Interior, acting through the USFWS, is authorized to list walrus and sea otter, seabirds, terrestrial plants and wildlife, and freshwater fish and plant species.

In addition to listing species under the ESA, the service agency (NMFS or USFWS) generally must designate critical habitat for listed species concurrently with the listing decision to the "maximum extent prudent and determinable" [16 U.S.C. §1533(a)(3)]. The ESA defines critical habitat as those specific areas that are occupied by the species at the time it is listed that are essential to the conservation of a listed species and that may be in need of special consideration, as well as those specific areas that are not occupied by the species that are essential to their conservation. Federal agencies are prohibited from undertaking actions that are likely to destroy or adversely modify designated critical habitat.

| Marine Mammals | Status |
|---|---|
| Blue whale *(Balaenoptera musculus)* | Endangered |
| Fin whale *(Balaenoptera physalus)* | Endangered |
| Humpback whale *(Megaptera novaeangliae)* | Endangered |
| Northern right whale *(Eubalaena glacialis)* | Endangered |
| Sei whale *(Balaenoptera borealis)* | Endangered |
| Sperm whale *(Physeter macrocephalus)* | Endangered |

| | |
|---|---|
| **<u>Sea Turtles</u>** | |
| Green turtle *(Chelonia mydas)* | *Endangered/Threatened |
| Hawksbill sea turtle *(Eretmochelys imbricata)* | Endangered |
| Kemp's ridley sea turtle *(Lepidochelys kempii)* | Endangered |
| Leatherback sea turtle *(Dermochelys coriacea)* | Endangered |
| Loggerhead sea turtle *(Caretta caretta)* | Threatened |
| Olive ridley sea turtle *(Lepidochelys olivacea)* | Threatened |
| | |
| **<u>Critical Habitat</u>** | |
| Northern right whale | Endangered |
| | |
| **<u>Finfish</u>** | |
| Smalltooth sawfish *(Pristis pectinata)* | Endangered |

*Green sea turtles in U.S. waters are listed as threatened except for the Florida breeding population, which is listed as endangered. Due to the inability to distinguish between the populations away from the nesting beaches, green sea turtles are considered endangered wherever they occur in U.S. waters.

*Sea Turtles*

NMFS has taken several steps in the past few years to reduce sea turtle bycatch and bycatch mortality in domestic longline fisheries. On March 30, 2001, NMFS implemented via interim final rule requirements for U.S. flagged vessels with pelagic longline gear on board to have line clippers and dipnets to remove gear on incidentally captured sea turtles (66 FR 17370). Specific handling and release guidelines designed to minimize injury to sea turtles were also implemented. NMFS published a final report which provides the detailed guidelines and protocols (Epperly *et al*., 2004) and a copy can be found at http://www.nmfs.noaa.gov/sfa/hms/Protected%20Resources/TM_524.pdf

A Biological Opinion completed on June 14, 2001, found that the actions of the pelagic longline fishery jeopardized the continued existence of loggerhead and leatherback sea turtles. This document reported that the pelagic longline fishery interacted with an estimated 991 loggerhead and 1,012 leatherback sea turtles in 1999. The estimated take levels for 2000 were 1,256 loggerhead and 769 leatherback sea turtles (Yeung 2001).

On July 13, 2001 (66 FR 36711), NMFS published an emergency rule that closed the Northeast Distant (NED) area to pelagic longline fishing (effective July 15, 2001), modified how pelagic longline gear may be deployed effective August 1, 2001, and required that all longline vessels (pelagic and bottom) post safe handling guidelines for sea turtles in the wheelhouse. On December 13, 2001 (66 FR 64378), NMFS extended the emergency rule for 180 days through July 8, 2002. On July 9, 2002, NMFS published a final rule (67 FR 45393) that closed the NED to pelagic longline fishing. As part of the Reasonable and Prudent Alternative, the BiOp required NMFS to conduct an experiment with commercial fishing vessels to test fishery-specific gear modifications to reduce sea turtle bycatch and mortality. This rule also required the length of any gangions to be 10 percent longer than the length of any floatline on vessels where the length of both is less than 100 meters; prohibited stainless steel hooks; and required gillnet vessel operators and observers to report any whale sightings and required gillnets to be checked every 0.5 to 2 hours.

The experimental program required in the BiOp was initiated in the NED area in 2001 in cooperation with the U.S. pelagic longline fleet that historically fished on the Grand Banks fishing grounds. The goal of the experiment was to test and develop gear modifications that might prove useful in reducing the incidental catch and post-release mortality of sea turtles captured by pelagic longline gear while striving to minimize the loss of target catch. The experimental fishery had a three-year duration and utilized 100 percent observer coverage to assess the effectiveness of the measures. The gear modifications tested in 2001 included blue-dyed squid and moving gangions away from floatlines. In 2002, the NED experimental fishery examined the effectiveness of whole mackerel bait, squid bait, circle and "J" hooks, and reduced daylight soak time in reducing the capture of sea turtles. The experiment tested various hook and bait type combinations in 2003 to verify the results of the 2002 experiment.

On November 28, 2003, based on the conclusion of the three-year NED experiment, and preliminary data that indicated that the Atlantic pelagic longline fishery may have exceeded the Incidental Take Statement in the June 14, 2001, BiOp, NMFS published a Notice of Intent to prepare an SEIS to assess the potential effects on the human environment of proposed alternatives and actions under a proposed rule to reduce sea turtle bycatch (68 FR 66783). A new BiOp for the Atlantic pelagic longline fishery was completed on June 1, 2004. The BiOp concluded that long-term continued operation of the Atlantic pelagic longline fishery, authorized under the 1999 FMP, was not likely to jeopardize the continued existence of loggerhead, green, hawksbill, Kemp's ridley, or olive ridley sea turtles; and was likely to jeopardize the continued existence of leatherback sea turtles.

On July 6, 2004, NMFS implemented additional regulations for the Atlantic pelagic longline fishery to further reduce the mortality of incidentally caught sea turtles (69 FR 40734). These measures include requirements on hook type, hook size, bait type, dipnets, lineclippers, and safe handling guidelines for the release of incidentally caught sea turtles. These requirements were developed based on the results of the 2001 – 2003 NED experiment (Watson *et al*., 2003; Watson *et al*., 2004a; Shah *et al*., 2004). These requirements are predicted to decrease the number of total interactions, as well as the number of mortalities, of both leatherback and loggerhead sea turtles (NMFS, 2004c). Post-release mortality rates are expected to decline due to a decrease in the number of turtles that swallow hooks which engage in the gut or throat, a decrease in the number of turtles that are foul-hooked and improved handling and gear removal protocols. NMFS is working to export this new technology to pelagic longline fleets of other nations to reduce global sea turtle bycatch and bycatch mortality. U.S gear experts have presented this bycatch reduction technology and data from research activities at approximately 15 international events that included fishing communities and resource managers between 2002 and mid-2005 (NMFS, 2005).

Internationally, the United States is pursuing sea turtle conservation through international, regional, and bilateral organizations such as ICCAT, the Asia Pacific Fisheries Commission, and FAO Committee on Fisheries (COFI). The United States intends to provide a summary report to FAO for distribution to its members on bycatch of sea turtles in U.S. longline fisheries and the research findings as well as recommendations to address the issue. At the 24th session of COFI held in 2001, the United States distributed a concept paper for an international technical experts meeting to evaluate existing information on turtle bycatch, to facilitate and standardize collection of data, to exchange information on research, and to identify and consider solutions to reduce turtle bycatch. COFI agreed that an international technical meeting could be useful despite the lack of agreement on the specific scope of that meeting. The United States has developed a prospectus for a technical workshop to address sea turtle bycatch in longline fisheries as a first step. Other gear-specific international workshops may be considered in the future.

*Smalltooth sawfish*

On April 1, 2003, NMFS listed smalltooth sawfish as an endangered species (68 FR 15674) under the Endangered Species Act (ESA). After reviewing the best scientific and commercial information, the status review team determined that the U.S. DPS (Distinct Population Segment) of smalltooth sawfish is in danger of extinction throughout all or a significant portion of its range from a combination of the following four listing factors: the present or threatened destruction, modification, or curtailment of habitat or range; over utilization for commercial, recreational, scientific, or educational purposes; inadequacy of existing regulatory mechanisms; and other natural or manmade factors affecting its continued existence. NMFS is working on designating critical habitat for smalltooth sawfish.

NMFS believes that smalltooth sawfish takes in the shark gillnet fishery are rare given the high rate of observer coverage. The fact that there were no smalltooth sawfish caught during 2001, when 100 percent of the fishing effort was observed, indicates that smalltooth sawfish takes (observed or total) most likely do not occur on an annual basis. Based on this information, the 2003 BiOp estimates that one incidental capture of a sawfish (released alive) over the next five years, will occur as a result of the use of gillnets in this fishery (NMFS, 2003a).

Smalltooth sawfish have been observed caught (eight known interactions, seven released alive, one released in unknown condition) in shark bottom longline fisheries from 1994 through 2004 (A. Morgan pers. comm., 2003). Based on these observations, expanded sawfish take estimates for 1994 – 2002 were developed for the shark bottom longline fishery (NMFS, 2003a). A total of 466 sawfish were estimated to have been taken in this fishery during 1994 – 2002, resulting in an average of 52 per year. It is important to note that all of the sawfish takes observed, except for one, were released alive.

#### 3.9.9.3 Interactions with Seabirds

Observer data from 1992 through 2005 indicate that seabird bycatch is relatively low in the U.S. Atlantic pelagic longline fishery (Table 3.29). Since 1992, a total of 129 seabird interactions have been observed, with 95 observed killed (73.6 percent). In 2005, there were 110 active U.S. pelagic longline vessels fishing for swordfish in the Atlantic Ocean, Gulf of Mexico, and Caribbean Sea that reportedly set approximately 5.9 million hooks. A total of four seabirds were observed taken.

The National Plan of Action (NPOA) for Reducing the Incidental Catch of Seabirds in Longline Fisheries was released in February 2001. The NPOA for Seabirds calls for detailed assessments of longline fisheries, and, if a problem is found to exist within a longline fishery, for measures to reduce seabird bycatch within two years. NMFS, in collaboration with the appropriate Councils and in consultation with the U.S. Fish and Wildlife Service, will prepare an annual report on the status of seabird mortality for each longline fishery. The United States is committed to pursuing international cooperation, through the Department of State, NMFS, and U.S. Fish and Wildlife Service, to advocate the development of National Plans of Action within relevant international fora. NMFS intends to meet with longline fishery participants and other members of the public in the future to discuss possibilities for complying with the intent of the plan of action. Because interactions appear to be relatively low in Atlantic HMS fisheries, the adoption of immediate measures is unlikely.

Bycatch of seabirds in the shark bottom longline fishery has been virtually non-existent. A single pelican has been observed killed from 1994 through 2005. No expanded estimates of seabird bycatch or catch rates for the bottom longline fishery have been made due to the rarity of seabird takes.

### 3.9.10 Measures to Address Protected Species Concerns

NMFS has taken a number of actions designed to reduce interactions with protected species over the last few years. Bycatch reduction measures have been implemented through the Fishery Management Plan for Atlantic Tunas, Swordfish and Sharks (NMFS, 1999), in Regulatory Amendment 1 to the 1999 FMP (NMFS, 2000), in Regulatory Adjustment 2 to the 1999 FMP (NMFS, 2002), in Amendment 1 to the 1999 FMP (NMFS, 2003a), and in the June 2004 Final Rule for Reduction of Sea Turtle Bycatch and Bycatch Mortality in the Atlantic Pelagic Longline Fishery (69 FR 40734). NMFS closed the Southeast U.S. Restricted Area to gillnet fisheries from February 15, 2006, to March 31, 2006, as a result of an entanglement and subsequent mortality of a right whale with gillnet gear (71 FR 8223). NMFS continues to monitor observed interactions with marine mammals and sea turtles on a quarterly basis and reviews data for appropriate action, if any, as necessary.

### 3.9.11 Bycatch of HMS in Other Fisheries

NMFS is concerned about bycatch mortality of Atlantic HMS in any Federal or state-managed fishery which captures them. NMFS plans to address bycatch of these species in the appropriate FMPs through coordination with the responsible management body. For example, capture of swordfish and tunas incidental to squid trawl operations is addressed in the Squid, Mackerel, and Butterfish FMP. Capture rates of tunas in coastal gillnet fisheries are being explored through issuance of exempted fishing permits and reporting requirements. NMFS continues to solicit bycatch data on HMS from all state, interjurisdictional, and Federal data collection programs. NMFS supports development of an interstate management plan for coastal sharks by the ASMFC to protect sharks caught incidentally in state-managed fisheries. NMFS has requested assistance from the ASMFC, GSMFC, and Atlantic and Gulf Regional Fishery Management Councils in identifying potential sources of bycatch of finetooth sharks in state waters fisheries or other fisheries outside the jurisdiction of this FMP.

### 3.9.11.1 Squid Mid-Water Trawl

U.S. squid trawl fishermen, using mid-water gear, landed 8.6 mt ww of yellowfin tuna, skipjack tuna, albacore tuna, bigeye tuna, and swordfish in 2003 incidental to the squid, mackerel, and butterfish trawl fishery (Table 3.108). Bycatch of HMS in other trawl fisheries may be included as a portion of the overall reported trawl landings in Table 3.108. Landings decreased from 2002 for bigeye and albacore tuna, and increased slightly for yellowfin and skipjack tuna. Swordfish landings increased by 50 percent but remain at a low level relative to the directed fishery landings. A retention limit of five swordfish per trip allows squid trawl fishermen with swordfish limited access permits to land some of the swordfish that are encountered, although regulatory discards still occur.

### 3.9.11.2 Menhaden Purse Seine Fishery

In the menhaden purse seine fishery, sharks were caught incidentally in approximately 30 percent of the purse seine sets observed (deSilva *et al.*, 2001). Ten species of sharks were identified with blacktip sharks being the most common species. Approximately 20 percent of the sharks were not identified to species. An estimated 30,000 sharks were taken in this fishery annually in 1994 and 1995. At the time of release, 75 percent of sharks were dead, 12 percent were disoriented, and eight percent were healthy. The odds of observing shark bycatch was highest in April and May. Stomach analyses of sharks suggest that their occurrence in the fishery is probably the result of sharks preying on gulf menhaden (deSilva *et al.*, 2001). No new data are available at this time.

Industry workers in this fishery employ a fish excluder device to reduce the retention of sharks and other large species (Rester and Condrey, 1999). In addition, a recently introduced hose cage modification may prove to be effective in reducing shark bycatch. These devices vary in effectiveness and no standards exist for such bycatch reduction measures in this fishery. In addition, there are currently no reporting requirements for takes of sharks in the menhaden purse seine fishery. Recent estimates of large coastal sharks discarded in this fishery range from 24,000 – 26,200 individuals (Cortés, 2005).

### 3.9.11.3 Shrimp Trawl Fishery

Shark bycatch in the shrimp trawl fishery consists mainly of sharks too small to be highly valued in the commercial market. As a result, few sharks are retained. Bycatch estimates of LCS in this fishery have been generated and were reviewed in the most recent LCS assessment (Cortés *et al*. 2002). Cortés (2002) estimated bycatch in the south Atlantic shrimp trawl fishery (North Carolina, South Carolina, Georgia, and Florida) for Atlantic sharpnose, bonnethead, and finetooth sharks based on expansion by fishing effort. Annual estimates of bycatch ranged from zero to almost six million sharks from 1992 to 1997 (Table 3.109) (Cortés, 2002). The 2002 SCS assessment included estimates of SCS bycatch because they were likely to exceed the actual landings for those species (Cortés, 2002). However, requirements for turtle excluder devices in this fishery have probably resulted in less bycatch because sharks are physically excluded from entering the gear.

**Table 3.109 Expanded estimates of bycatch (number of fish) of bonnethead, Atlantic sharpnose, and finetooth sharks in the U.S. south Atlantic shrimp trawl fishery based on within stratum expansion by effort as trips by fishing year.** Source: Cortés, 2002.

| 1996-97 | 19,320 | 38,517 | 358,457 | 0 |

Bycatch of the SCS complex in the Gulf of Mexico shrimp trawl fishery consists mainly of Atlantic sharpnose and bonnethead sharks (Cortés, 2002). Estimates of the bycatch of SCS in this fishery ranged from 3.2 to 1.3 million sharks per year from 1972 - 2000 (Table 3.110). Finetooth sharks were added as a select species for the shrimp trawl observer program in 2005 to help determine if this fishery has bycatch of finetooth sharks. Prior to this, data on finetooth shark bycatch was not recorded.

#### 3.9.11.4 Southeast Gillnet Fishery

Gillnet fisheries operating in the south Atlantic, particularly off Florida, have been shown to incidentally take various species of sharks (see Section 4.2.2 for full description). These fisheries are primarily targeting Spanish mackerel and whiting (kingfish). Vessels participating in these fisheries either have a mackerel permit and a commercial shark permit which allows retention and landing of sharks, or may be operating in an unmanaged fishery (whiting) that requires no permit at this time. Vessels operating in these fisheries and holding a Federal permit are required to file trip reports (Coastal Fisheries Logbook). Preliminary data from observed gillnet trips not targeting sharks indicate that Atlantic sharpnose, bonnethead, blacktip, finetooth, scalloped hammerhead, blacknose, spinner and tiger sharks were caught (Carlson and Bethea, 2006). Expanding observer coverage in South Atlantic gillnet fisheries that are landing sharks could provide additional data on the extent of the bycatch of HMS species in these fisheries and thereby improving the stock assessments for these species. NMFS will attempt to continue expanded observer coverage in these fisheries as resources allow.

### 3.9.12 Effectiveness of Existing Time/Area Closures in Reducing Bycatch

During the past several years, NMFS has implemented several time/area closures in the Atlantic Ocean and Gulf of Mexico for the PLL fishery to reduce discards and bycatch of a number of species (juvenile swordfish, bluefin tuna, billfish, sea turtles, etc.). Analyses of the effectiveness of these closures are included in Section 4.1.2 and summarized here.

The combined effects of the individual area closures were examined by comparing the 2001 – 2003 catch and discards to the averages for 1997 – 1999 throughout the entire U.S. Atlantic fishery. Changes in the numbers of fish caught and discarded were compared to the predicted values from Regulatory Amendment 1 to the 1999 FMP (NMFS, 2000). Overall effort, expressed as the number of hooks set, declined by 15 percent between the two time periods. Declines were noted for both the numbers of kept and discards of all species examined including swordfish, tunas, sharks, billfish, and sea turtles. The number of reported discards of swordfish, bluefin and bigeye tuna, pelagic sharks, dolphin, wahoo, blue and white marlin, sailfish, and spearfish all declined by more than 30 percent. The reported discards of blue and white marlin declined by about 50 percent and sailfish discards declined by almost 75 percent. The reported number of sea turtles caught and released declined by almost 28 percent.

The reported declines in swordfish kept and discarded, large coastal sharks kept and discarded, and dolphin kept were similar to the predicted values developed for Regulatory Amendment 1. Reported discards of bluefin tuna, pelagic sharks, all billfish (with the exception of spearfish for which no predicted change was developed in Regulatory Amendment 1), and total BAYS tunas kept all declined more than the predicted values.

#### 3.9.12.1 Prohibition of Live Bait in the Gulf of Mexico

Regulatory Amendment 1 to the 1999 FMP also prohibited the use of live bait on pelagic longline gear in the Gulf of Mexico due to concerns over the incidental bycatch of billfish. Based on logbook data, the number of hooks reported set with live bait or a combination of live and dead bait in the Gulf of Mexico decreased from 22.7 percent in 2000, to less than 0.1 percent in 2003 (Table 3.111). However, the number of hooks reported set with no bait type specified increased from zero in 1999 – 2001 to 3.7 percent in 2003, but declined to less than one percent in 2004. Also, the reported number of hooks set in the Gulf of Mexico has increased in recent years. The reported effort in 2004 represents an increase of 21.8 percent from 2000. NMFS will continue to analyze the effectiveness of the live bait prohibition in the Gulf of Mexico pelagic longline fishery.

**Table 3.111 Comparison of the number of hooks reported set in the Gulf of Mexico with dead or live bait, or a combination of both baits, 1999-2004 (numbers in parentheses are percent of the total number of hooks set in the Gulf of Mexico).** Source: PLL Logbook data.

### 3.9.12.2 Conclusions

The time/area closures and live bait prohibition in the Gulf of Mexico have been relatively successful at reducing bycatch in the HMS pelagic longline fishery. Reported discards of all species of billfish have declined (Table 4.8). The reported number of turtles caught, swordfish discarded, bluefin tuna discarded, and pelagic and large coastal shark discards have also declined. However, the reported number of target species kept, such as swordfish and BAYS tuna, have decreased more than was predicted. This is contrary to the other objective of the time/area closures, which was to minimize the reduction in target catch. NMFS will continue to analyze these measures as additional data become available and examine the effects of ongoing regulatory change over time.

### 3.9.13 Evaluation of Other Bycatch Reduction Measures

NMFS continues to monitor and evaluate bycatch in HMS fisheries through direct enumeration (pelagic and bottom longline observer programs, shark gillnet observer program), evaluation of management measures (closed areas, trip limits, gear modifications, etc.), and vessel monitoring systems (VMS).

The following section provides a review of additional management measures or issues that may address bycatch reduction:

- Atlantic Large Whale Take Reduction Plan (ALWTRP) regulations

Observers were placed on shark gillnet vessels during the 2005 season and covered 33 strikenet and 31 driftnet sets during and outside of right whale calving season (Carlson and Bethea, 2006). In addition, observers were placed on vessels fishing with sink gillnets as part of a pilot program and observed 88 sets. Protected species interactions occurred with all three types of gear. One leatherback and four loggerhead sea turtles were observed with all but one loggerhead released alive. One loggerhead was observed taken by strikenet and one with sink net. Both were released alive. No marine mammals or smalltooth sawfish were observed taken. NMFS has published a proposed rule to modify the right whale areas and the time periods when 100 percent observer coverage would be required (70 FR 35894; 21 June 2005).

- Atlantic Bottlenose Dolphin Take Reduction Team

Due to the observed takes of Atlantic bottlenose dolphin in the shark drift gillnet fishery, representatives of the fishery have been included in the Atlantic Bottlenose Dolphin Take Reduction Team. The Team held seven meetings during 2001 – 2003 and developed a set of recommendations which formed the basis for a TRP. NMFS published a proposed rule on November 10, 2004, to implement the TRP (69 FR 65127), and a final rule was published on April 26, 2006 (71 FR 24776). Included in the final rule are: 1) effort reduction measures; 2) gear proximity rules; 3) gear or gear deployment modifications; 4) fishermen training; and 5) outreach and education measures to reduce dolphin bycatch below the stock’s potential biological removal level. The final rule also includes time/area closures and size restrictions on large mesh fisheries to reduce incidental takes of endangered and threatened sea turtles as well as to reduce dolphin bycatch.

- MMPA List of Fisheries Update/Stock Assessment

NMFS continues to update the MMPA List of Fisheries and the 2005 final list is available at http://www.nmfs.noaa.gov/pr/pdfs/fr/fr71-247.pdf. The proposed 2006 List of Fisheries published on April 24, 2006 (71 FR 20941). Final 2005 marine mammal stock assessment reports and draft 2006 reports are also available. See Section 3.9.9.1 for information on obtaining these reports.

- Atlantic Offshore Cetacean Take Reduction Team (AOCTRT)

NMFS has disbanded the AOCTRT due to the fact that two of the three fisheries addressed by the AOCTRT were closed by fishery management actions, leaving only the pelagic longline fishery in operation. This fishery has been the subject of recent fishery management actions and increased observer coverage related to bycatch. As discussed below, a take reduction team specific to the pelagic longline fishery has been formed.

- Pelagic Longline Take Reduction Team (PLTRT)

NMFS appointed a PLTRT in June 2005, to address marine mammal interactions in the longline fishery, specifically pilot whales. As required by the MMPA, the PLTRT must develop a TRP within eleven months. The PLTRT has met four times since and a draft TRP should be available shortly. NMFS intends to continue reviewing the fishery and any marine mammal interactions to determine if additional take reduction measures are necessary.

- Observer coverage of shark drift gillnet fleet

On March 30, 2001, NMFS reduced the level of observer coverage required in the shark drift gillnet fishery from 100 percent year-round to 100 percent during right whale calving season and to a statistically significant level during the rest of the year. Recent scientific analyses indicate that a 33.8 percent level of coverage is statistically significant and adequate to provide reasonable estimates of sea turtle and marine mammal takes outside of the right whale calving season. The level of observer coverage necessary will be re-evaluated annually and adjusted accordingly. During the 2005 season, 33 strikenet and 31 driftnet sets were observed (Carlson and Bethea, 2006). No interactions with marine mammals were observed in either drift gillnet or strikenet sets. Four loggerhead sea turtles were observed caught in drift gillnet sets (three released alive, one released injured and assumed to be dead). One leatherback sea turtle was caught in drift gillnet gear and released alive. NMFS began placing observers on vessels with directed shark permits that were targeting species other than sharks in 2005. Management options to address issues in the shark drift gillnet fishery, particularly overfishing of finetooth sharks, are considered in this document.

- Vessel monitoring systems in the pelagic longline fishery

NMFS adopted fleet-wide VMS requirements in the Atlantic pelagic longline fishery in May 1999, but was subsequently sued by an industry group. By order dated September 25, 2000, the U.S. District Court for the District of Columbia prevented any immediate implementation of VMS in the Atlantic pelagic longline fishery, and instructed to "undertake further consideration of the scope of the [VMS] requirements in light of any attendant relevant conservation benefits." On October 15, 2002, the court issued a final order that denied plaintiff's objections to the VMS regulations. Based on this ruling, NMFS implemented the VMS requirement in September 2003.

- Vessel monitoring systems in other HMS fisheries

Starting in 2004, gillnet vessels with a directed shark permit and gillnet gear onboard were required to install and operate a VMS unit during the Right Whale Calving Season (November 15 – March 31). In an attempt to better quantify bycatch, NMFS will require all vessels with Limited Access Shark Permits to participate in the Directed Shark Gillnet Observer program. Directed shark bottom longline vessels located between 33$^{o}$ N and 36$^{o}$ 30' N need to install and operate a VMS unit from January through July.

## CHAPTER 4 LIST OF FIGURES

# 4.0 ENVIRONMENTAL CONSEQUENCES OF ALTERNATIVES

## 4.1 Bycatch Reduction

### 4.1.1 Workshops

The 1999 FMP identified reducing bycatch and bycatch mortality as a critical management goal pursuant to National Standard 9 of the Magnuson-Stevens Fishery Conservation and Management Act (MSA). The October 29, 2003, Biological Opinion (BiOp) for the Atlantic shark fishery and the June 1, 2004, BiOp for the Atlantic pelagic longline fishery recommend and in some cases require further actions to reduce bycatch and bycatch mortality of protected resources in the HMS fisheries. The following sections evaluate a number of alternatives to meet these goals. Workshops enabling fishermen to become more proficient with the techniques, protocols, and equipment for dehooking and disentanglement of protected resources, as well as proper identification of these species, are an integral component to ensuring that the post-release mortality reduction goals are realized.

#### *4.1.1.1 Protected Species Safe Handling, Release, and Identification Workshops for Pelagic Longline, Bottom Longline, and Gillnet Fishermen*

The October 2003 Biological Opinion for the Atlantic shark fishery determined that the shark fishery (*i.e.*, bottom longline and drift gillnet) is not likely to jeopardize the continued existence of endangered green, leatherback, and Kemp's ridley sea turtles, endangered smalltooth sawfish, threatened loggerhead turtles, or adversely affect marine mammals. However, it requires the implementation of workshops or other programs to distribute information on gear handling techniques, protocols for gear entanglements and the safe release of protected species, information on smalltooth sawfish, and HMS requirements and regulations to reduce serious injuries or mortalities (NMFS, 2003). The June 2004 BiOp for the Atlantic pelagic longline fishery required that all captains or operators be proficient with the safe release and disentanglement gears and protocols due, in part, to a jeopardy conclusion for leatherback sea turtles (NMFS, 2004a). The protected species release, disentanglement and identification workshops are intended to help further reduce the mortality of sea turtles, smalltooth sawfish, and other protected resources captured incidentally in the HMS pelagic (PLL) and bottom (BLL) longline and shark gillnet fisheries. Through these workshops, participants would be trained to safely disentangle, resuscitate, release, and identify protected species, as per the current NMFS standards for the pelagic and bottom longline fisheries. Participants may also receive instruction on disentanglement and release for protected resources that lack formal protocols. The incidental take statements issued in the October 2003 and June 2004 BiOps were contingent upon fishermen becoming increasingly proficient with required release equipment and protocols, while reducing the number of sea turtle mortalities resulting from longline and gillnet interactions over time. The dissemination of this information is an important element in further reducing post-release mortality of protected resources in the PLL, BLL, and shark gillnet fisheries.

In addition to BiOp requirements, the Pelagic Longline Take Reduction Team has recommended the implementation of a mandatory certification program for owners and operators of pelagic longline vessels, as one measure for reducing the bycatch and bycatch mortality of long-finned pilot whales (*Globicephala melas*), short-finned pilot whales (*Globicephala macrorhynchus*), common dolphins (*Delphinus delphis*), and other protected species in the Atlantic pelagic longline fishery. Specifically, the recommendation suggests that the certification program incorporate safe handling and release techniques; disseminate information on relevant regulations; provide guidelines specific to marine mammal bycatch in the fishery; an explanation of information that needs to be recorded in log books and auxiliary forms; provideguidelines for operator communications; provide updates on NMFS observer program; description of research and monitoring projects aimed to reduce marine mammal bycatch; and species identification.

The protected species safe handling, release, and identification workshops would be held at several locations to minimize travel costs for most participants and during non-peak fishing times to minimize disruptions to fishing activities. The workshops would be held in areas where there is a high concentration of permit holders, according to the addresses provided when applying for an HMS permit. A schedule of workshops would be released in advance to provide fishermen with an opportunity to attend the workshop most convenient to them. The Agency may provide an opportunity for the industry to schedule one-on-one training at the expense of the individual, if they are unable to attend any of the previously scheduled workshops.

The individuals that attended the PLL industry-sponsored safe handling and release workshops would be grandfathered-in to the requirements for all of the preferred alternatives, meaning all owners and operators that attended and successfully completed the industry certification workshops, as documented by workshop facilitators, held on April 8, 2005, in Orlando, Florida, and on June 27, 2005, in New Orleans, Louisiana, would automatically receive valid protected species workshop certificates. To the extent practicable, anyone who attends and successfully completes the hands on training could be certified (*e.g.*, enforcement, crew, environmentalists, and recreational fishermen). Priority would be given to those who are required to be certified if space is an issue.

In order to ensure that fishery participants are able to use the release and disentanglement equipment effectively, workshop participants would be given hands-on instruction and a practical examination. Participants who successfully complete the workshops would receive a multi-year certification. A certificate would be required to be on board each longline and gillnet vessel during fishing operations and would serve as proof that the participant completed the necessary training workshop.

The Agency received public comment both in support of and opposed to the protected species workshops. Some commenters were concerned about potential lost revenue on longline trips if bycatch were to be handled correctly. Some comments supported extending the workshop requirements to include all HMS fishermen, as well as expanding the release techniques to include additional species. NMFS received many comments suggesting that various combinations of owners, operators, and crew members be required to participate in the workshops. And if the crew members are not required to attend, then the operators should be responsible for training the crew. A few comments supported grandfathering in the industry certified individuals, so that they do not need to attend the mandatory workshops. Additionally, the Agency received comment on the recertification timeframes, and provided recommendations for scheduling and selecting venues to mitigate any negative impacts to participants. The Agency has considered all of these comments when selecting the final alternatives.

As described in Chapter 2, the alternatives considered for pelagic longline, bottom longline, and gillnet fishery workshops are:

A1 Voluntary protected species safe handling, release, and identification workshops for longline fishermen (No Action)

*A2 Mandatory protected species safe handling, release, and identification workshops and certification for all HMS pelagic or bottom longline vessel owners – Preferred Alternative*

*A3 Mandatory protected species safe handling, release, and identification workshops and certification for vessel operators actively participating in HMS pelagic and bottom longline fisheries – Preferred Alternative*

A4 Mandatory protected species safe handling, release, and identification workshops and certification for all HMS longline vessel owners, operators, and crew

*A5 Mandatory protected species safe handling, release, and identification workshops and certification for shark gillnet vessel owners and operators – Preferred Alternative*

*A6 Protected species safe handling, release, and identification certification renewal (every 3-years) – Preferred Alternative*

*Ecological Impacts*

A summary of protected species interactions in the HMS PLL, BLL, and gillnet fisheries are found in Table 4.1, 4-4Table 4.2, and Table 4.3, respectively. More information on gear-specific HMS fisheries as well as observed and extrapolated takes of protected species is provided in Chapter 3. The June 2004 BiOp sets specific post-release mortality (PRM) targets for the PLL fishery that decrease each year starting at 32.8 in 2004 and declining to 13.1 percent in 2007 for leatherback turtles and from 21.8 to 17 percent for loggerhead sea turtles during the same years. While NMFS does not have estimates of PRM for BLL and gillnet gears, observed estimates of protected species takes are available and are summarized in Table 4.2 and Table 4.3.

**Table 4.1 Extrapolated Total Sea Turtle and Marine Mammal Interactions in the HMS PLL fishery for 1999-2005 and the 3 Year ITSs for 2004-2006 and 2007-2009.** Sources: Yeung, 2001; Garrison, 2003; Garrison and Richards, 2004; Garrison, 2005; NMFS, 2004b; Walsh and Garrison, 2006

* All values include total takes with mortalities listed in parentheses. Extrapolated estimates of the drift gillnet fishery were provided for the 1999-2002 period and 2003-2005 are observed interactions for the entire shark gillnet fishery.

Under alternative A1, the No Action alternative, NMFS would continue to provide voluntary workshops for longline fishermen and continue to distribute wheelhouse placards, the safe release protocols, and educational videos, as well as additional information through the activities of the NMFS PLL Point of Contact (POC). Two separate PLL industry-sponsored workshops were held on April 8, 2005, in Orlando, Florida, and on June 27, 2005, in New Orleans, Louisiana, to teach the safe handling and release protocols for sea turtles. NMFS hosted a series of nine voluntary workshops in June 2005 that included instruction on the safe handling and release of protected resources in the commercial shark fishery; however, these voluntary workshops were poorly attended. Furthermore, the Agency is engaged in a proposed rulemaking (March 29, 2006, 71 FR 15680) that would update the requirements for dehooking equipment that must be possessed, maintained, and utilized by participants in the Atlantic shark BLL fishery, and additional training in the use of this new equipment may be necessary.

This alternative could provide some positive ecological impacts by continuing to provide voluntary workshops and outreach activities through the NMFS PLL POC. A critical component of achieving the post-release mortality targets is to ensure that participants in the PLL fisheries are proficient with the safe handling, dehooking, and resuscitation techniques, including the proper use of all the required equipment. These efforts would increase the amount of gear removed from sea turtles, increasing their probability of survival. To comply with the BiOps, voluntary hands-on training would be provided for participants in the longline fisheries. Additionally, NMFS would continue to distribute wheelhouse placards, safe release protocols, educational videos, and additional information as needed.

Alternative A1 would not maintain compliance with the October 2003 or June 2004 BiOps because attendance at these workshops would not be mandatory and may not result in the certification of operators. Alternative A1 might reduce the post-release mortality of protected species captured in HMS fisheries; however, the voluntary nature of the workshops and minimal attendance observed thus far may limit the dissemination of the safe release, disentanglement, and protected resource identification information, reducing potential ecological benefits. Furthermore, it is essential that fishermen are able to properly identify the protected resources with which they interact, in order to comply with regulations. In the past, voluntary workshops have not been well attended. The post-release mortality targets established for the PLL fishery would not likely be met because current rates under the status quo exceed those targets, which could further jeopardize threatened or endangered sea turtles and result in negative ecological impacts to these species.

Alternative A2, a preferred alternative, would require mandatory protected species safe handling, release, and identification workshops and certification for all vessel owners that have pelagic or bottom longline gear on board their vessel and that have been issued or are required to be issued HMS limited access permits. To further strengthen the requirement for longline vessel owners to attend the protected species workshops, their attendance and demonstrated understanding of the handling, disentanglement, resuscitation, release, and identification techniques would be linked to the renewal of their HMS permit(s). Mandatory attendance and the link to the permit renewal would increase industry participation compared to the poorly attended voluntary workshops. Longline vessel owners would be required to obtain the workshop certification prior to renewing their HMS permit(s) in 2007. Proof of successful completion of a workshop would need to be submitted in order to renew a HMS permit(s), and those without a workshop certification would be prohibited from participating in HMS fisheries. Public comment both supported and opposed alternative A2, stating that mandatory owner attendance may discourage them from hiring inexperienced operators who may not know how to properly handle sea turtles and other protected resources, handling protected resources wastes time on money making trips, and owners of a vessel may not always be the vessel operator.

Alternative A2 would ensure that owners are aware of the certification requirement and the need for the PLL and BLL fisheries to meet or achieve the post-release mortality targets set in the 2004 BiOp (NMFS, 2004a). Alternative A2 would likely have positive ecological impacts. The ecological benefits of reduced post-release mortality would depend upon the number of longline owners who are active in the fishery and/or take the initiative to properly train the operators and crew working on their vessel. Longline vessels can have several different operators in any given year; therefore, the owner may not always be on board the vessel and able to disseminate the information and skills learned during the protected species workshops.

NMFS believes that allowing proxies to attend workshops on behalf of longline and gillnet vessel owners would reduce the likelihood that those involved in the operation of individual vessels would be the ones attending the workshops. NMFS is concerned that vessel owners would select proxies that are not involved in the day-to-day operation of their fishing operations, thus compromising the goal of these workshops. If permit holders were to send proxies involved with the day-to-day activities of the vessel (i.e., crew or operators), the permit holder runs the risk of having no proxy available on the boat due to the high turnover of crew and operators. The proxy may not be employed on permit holder's vessel for the entire three years that the permit is valid. Additionally, NMFS does not have the means to validate a connection between the permit holder and the proxy. It is important for vessel owners that are not actually involved in the day-to-day operations of their vessels to be aware of the regulations and management of the fisheries in which their vessels are participating in order to fully and effectively implement the techniques taught at the workshops. Vessel owners should be aware of the concepts and breadth of material, as well as the tools and techniques, that would be covered in the workshops to understand the requirements for engaging fishing activities with PLL, BLL or gillnets on board the vessel and to understand what is expected of the vessel's crew. Non-compliance with the requirements of the 2003 and 2004 BiOps could result in additional, more restrictive management measures in the future.

Based on the estimated takes presented in Table 4.1, there were an average of 969 leatherback and 696 loggerhead sea turtles interactions per year in the PLL fishery between 1999 and 2005. Until mid-2004, the standard hooks used by the industry were 7/0 and 9/0 J-hooks. In mid-2004, NMFS implemented mandatory circle hook and bait requirements in the fishery intended to reduce sea turtle bycatch and bycatch mortality. J-hooks can increase the number of sea turtle interactions and increase the likelihood of hook ingestion, compared to using circle hooks and specific baits (NMFS, 2004b). The post-release mortality target identified in the 2004 BiOp would require a 4.8 and 19.7 percent decrease in post release mortality for loggerhead and leatherback sea turtles, respectively, between 2004 and 2007 (NMFS, 2004a). Decreasing the post-release mortality is dependent upon vessel owners disseminating information from the workshops to operators and crew involved in fishing activities. As a result of the jeopardy finding for leatherback sea turtles, the 2004 BiOp included additional requirements for PLL closures or other comparable actions if the sea turtle incidental take and post-release mortality targets are not met (NMFS, 2004a). The potential for additional regulations imposed upon the fishery may provide adequate incentive for vessel owners to informally train their operators and crew. The Agency received public comment in favor of owners/operators being required to train all crew members onboard. NMFS encourages all workshop participants to disseminate this information to all crew members involved with haul-back or fishing activities, however, is not preferring an alternative requiring owners to train crew members at this time.

The October 2003 BiOp estimates that 42 percent of sea turtles die as a result of interactions with BLL gear. Table 4.2 shows the extrapolated estimates in the BLL fishery (1994 - 2002) and the observed interactions for 2003 and 2004. The post-release mortality has not been estimated for sea turtle interactions in the BLL fishery; therefore, it is difficult to estimate the post-release mortality reduction benefits of this alternative, but there may be positive ecological impacts from the transfer of safe release and disentanglement protocols to owners in the BLL fishery. NMFS is in the process of a rulemaking (March 29, 2006, 71 FR 15680) that would update the safe handling, release and disentanglement equipment for sea turtles and other non-target catch in this fishery. The current preferred alternative would require participants in the BLL fishery to possess, maintain, and utilize the same equipment and protocols currently required for the PLL fishery. While the available data show that the BLL fishery has fewer interactions with sea turtles than the PLL fishery, the BLL fishery is not currently required to use circle hooks or specific baits to reduce sea turtle interactions.

In addition to providing information and ensuring proficiency with the safe handling, dehooking, and release of sea turtles, these workshops would also include information on the proper techniques for safe release of smalltooth sawfish. Extrapolated estimates indicate that, on average, the BLL fishery interacts with 52 smalltooth sawfish a year (Table 4.2). The October 2003 BiOp found that Atlantic shark fisheries would result in the temporary disturbance of behavior and short term injury of smalltooth sawfish, but fishing activities are not expected to affect the reproduction of the individuals that are caught, nor result in mortality. Alternative A2 would ensure BLL vessel owners understand safe release techniques, which would likely reduce any mortality of smalltooth sawfish. Ecological benefits would likely be increased if vessel owners are involved in fishing activities or successfully train their operators and crew members in safe techniques covered in the workshops.

There have been no documented interactions between PLL gear and smalltooth sawfish to date. However, if PLL owners are aware of safe handling and release techniques, this information would likely benefit them in case of future interactions or if they participate in other fisheries. Since PLL fishermen are required to possess at least an incidental shark permit and because of the relative ease of modifying pelagic to bottom longline, fishermen could set bottom longline gear on their way back to port, target sharks or other species, and potentially interact with smalltooth sawfish.

In addition to safe release and disentanglement protocols, alternative A2 would also provide information related to the proper identification of protected species. The proper identification of protected species listed under the ESA or MMPA is an important skill for PLL and BLL vessel owners to possess. The MMPA classifies the PLL and BLL fishery as Category I and III, respectively. A Category I fishery results in frequent serious injuries and mortalities of marine mammals, whereas a Category III fishery has a remote likelihood or no known serious injuries or mortalities. Most longline interactions with marine mammals are in the PLL fishery. Species commonly encountered include: Risso's dolphin; pilot whales; pygmy sperm whales; beaked whales; spotted dolphins; common dolphin; and, Minke whales. Table 4.1 contains the estimated interactions with marine mammals in the PLL fisheries. The shark BLL fishery has only interacted with two marine mammals (Delphinids) between 1994 and 2002. Improved identification skills may increase the accuracy of logbook data and assist fishermen in complying with the regulations.

Protected species can be difficult to identify, especially since interactions with them are a relatively rare occurrence. Alternative A2 would provide information on key morphological characteristics, distribution, and basic life history to improve identification of protected resources. Positive identification of sea turtles and marine mammals in fishermen's logbook reports could reduce uncertainty and increase the accuracy of extrapolated estimates of interactions by species. This is essential information for agency biologists, managers, and law enforcement officials who seek to increase the knowledge of home range, habitat use, and abundance. Furthermore, interactions with specific longline configurations (depth, hook type, bait, target-fish species) may assist fishermen, managers, gear experts, and scientists in designing experiments and gear to reduce interactions. Positive ecological impacts would likely occur as a result of disseminating this information to the longline vessel owners. In addition to benefiting protected resources, alternative A2 could benefit non-target HMS and other finfish by reducing post-release mortality by increasing the proficiency with the currently required dehooking and disentanglement equipment for sea turtles. Alternative A2 would likely result in positive ecological impacts, however, the extent of these impacts are dependent upon the dissemination of this information between owners and their operators and crew.

Alternative A3, a preferred alternative, would require mandatory protected species safe handling, release, and identification workshops and certification for HMS PLL and BLL vessel operators before the vessel's permit expires in 2007. This alternative would have ecological benefits similar to alternative A2; however, these benefits would be greater in magnitude as operators are generally directly involved in fishing activities, including gear retrieval, when sea turtles or other protected resources are most likely to be encountered. The initial operator certification would be linked to the renewal of the vessel's HMS LAP(s) in 2007; therefore, an operator would need to attend a workshop and receive the certification prior to the owner renewing any of the vessel's HMS LAP(s) in 2007. If the vessel owner holds multiple HMS LAPs, the operator would need to be certified prior to the earliest expiration date on any of the permits in 2007. After the initial certification, the operator's certification is no longer linked to the renewal of a vessel's HMS LAP and would need to be renewed prior to the expiration date on the operator's workshop certificate. The workshop certification would not be transferable any other person and would have the operator's name on the certificate. This alternative would ensure that at least one person directly involved with a vessel's fishing activities would be certified in the safe handling and release protocols and identification of protected resources.

Alternative A3 was supported by public comment. Commenters suggested that vessel operators should be certified and that they should, in turn, train each individual crew member working aboard their vessel to ensure that the crew is informed and that proper procedures are followed. Operators are encouraged to transfer the knowledge and skills obtained from successfully completing the workshops to the crew members, potentially increasing the proper release, disentanglement, and identification of protected resources. While this alternative would not require crew members to attend the workshops, to the extent practicable, the workshops would be open to anyone who wishes to attend and receive certification.

Alternative A4 would require owners, operators, and crew to attend protected species safe handling, release, and identification workshops and become certified. This alternative would certify the largest group of individuals involved with fishing activities, and therefore, would likely have the greatest positive ecological impact. Alternative A4 would provide similar benefits to those of alternatives A2 and A3 combined, in addition to including all crewmembers associated with a vessel's fishing activities. Vessel crew members are generally directly involved during gear retrieval activities as the operator may be operating the vessel from the wheelhouse. Furthermore, all of these participants would be provided with protected resource identification information, which would have positive ecological impacts, likely increasing proportionally to the number of individuals who attain certification. NMFS anticipates having several operators and/or crew members per HMS vessel permit attend these workshops, as vessels often have two operators and multiple crew members. Ensuring that operators and/or crew are skilled at handling and release of sea turtles and adept at identification of protected resources would increase the likelihood of achieving the post-release mortality targets prescribed by the 2004 BiOp. The Agency received several comments opposing the requirement to have crew certified because of their transient nature and the fact that some crew members are not U.S. citizens and may not be available to attend workshops.

An indirect positive ecological benefit of involving vessel owners, operators, and/or crew in these safe handling, resuscitation, release, and protected resource identification workshops, may be to promote or transfer this technology to other countries that also target HMS and other species with longline gear. Because of the migratory nature of most sea turtle species, these animals frequently travel thousands of miles and may enter into the jurisdiction of other nations or the high seas. Longline gear employed by different nations is relatively similar between countries, therefore, the protocols discussed and materials employed in these workshops could be translated by interested nations into languages appropriate for their use. Some materials are already available in English, Spanish, and Vietnamese. Since many HMS are managed by an international Atlantic-wide commission (ICCAT), there are numerous opportunities for transfer of technology between the United States and other ICCAT contracting parties, reinforcing the United States' role as a leader in global marine conservation.

Alternative A5, a preferred alternative, would mandate that all gillnet vessel owners issued a shark permit and operators of vessels employing this gear attend workshops on the safe release and disentanglement of protected resources, including sea turtles, smalltooth sawfish, and marine mammals and obtain certification before the vessel's HMS permit expires in 2007. The shark gillnet fishery currently has several requirements intended to reduce interactions and mortalities of protected species, such as observer coverage, net checks, and Atlantic Whale Take Reduction Plan (ALWTRP) requirements. This alternative may provide positive ecological impacts by reducing the mortality of protected species and teaching fishermen how to identify, disentangle, and safely release protected species. The Agency received public comment supporting alternative A5; however, requiring both owners and operators of these vessels to be certified was a concern. The Agency realizes that many vessel owners may not operate or be present on the vessels during fishing trips; therefore, certifying vessel owners ensures that they are aware of the certification requirements and protocols. The owners would then be accountable for having a certified operator on board while engaged in fishing activities.

As with the PLL and BLL requirements, the initial operator certification for gillnet vessels would be linked to the vessel's HMS permit renewal. An operator would be required to attend a workshop and receive the certification prior to the owner renewing the vessel's certification in 2007. The owner would be required to submit proof of certification before the HMS permit would be renewed. The initial operator certification would be linked to the renewal of the vessel's HMS LAP(s) in 2007. If the vessel owner holds multiple HMS LAPs, the operator would need to be certified prior to the earliest expiration date on any of the permits in 2007. After the initial certification, the operator's certification is no longer linked to the renewal of a vessel's HMS LAP and would need to be renewed prior to the expiration date on the operator's workshop certificate. The workshop certification would not be transferable any other person and would have the operator's name on the certificate. This alternative would ensure that at least one person directly involved with a vessel's fishing activities would be certified in the safe handling and release protocols and identification of protected resources.

This alternative may result in positive ecological impacts by increasing the industry awareness of the need to reduce protected species interactions, post-release mortality, and keep the number of interactions and mortalities below the five year ITS for sea turtles and smalltooth sawfish (Table 4.3). The combination of hands-on experience with the safe release and disentanglement protocols for sea turtle interactions with gillnets, as well as proper sea turtle identification and information on Atlantic shark regulations, would likely lead to decreased post-release mortalities in the shark gillnet fishery. Workshops will help train operators to safely handle and release sea turtles and reduce mortalities. While the interactions between gillnet gear and marine mammals are relatively low, the workshops could also provide a positive ecological impact through the education of vessel owners and operators regarding protected resource identification and release techniques for marine mammals (Table 4.3). Furthermore, the gillnet vessel owners and operators, who properly identify protected resources, would be able to apply the appropriate safe release and resuscitation protocols. Finally, proper species identification may improve the accuracy and usefulness of logbooks, as well as quota monitoring and stock assessments.

The Southeastern U.S. Atlantic shark gillnet fishery is listed as a Category II fishery under the MMPA indicating that occasional mortalities and serious injuries occur in this fishery (69 FR 48407). The listing is attributed to interactions with bottlenose dolphins, North Atlantic right whales, and Atlantic spotted dolphins. Category II fisheries are required to report incidental injuries and mortalities of marine mammals, accommodate an observer, if requested, and comply with the provisions of Take Reduction Plans (TRPs). Marine mammals are often difficult to identify due to the infrequency with which they are encountered in the gillnet fishery. It is essential for fishermen to know the morphological characteristics and distribution of protected resources to positively identify these animals to the species level. When marine mammals are encountered and properly recorded, the logbook reports provide significant information regarding home range, habitat use, and abundance. All of this information is important to Agency biologists, managers, and law enforcement officials because it may improve accuracy of stock assessments and quota monitoring. For these reasons, the protected resources identification component of these workshops would likely have positive ecological impacts for marine mammals.

On February 16, 2006, NMFS issued a temporary rule (February 16, 2006, 71 FR 8223) that prohibited the use of all gillnet gear in the Atlantic Right Whale Calving Area until March 31, 2006, because of a right whale calf interaction with gillnet gear. Dissemination of information related to release and disentanglement of marine mammals from gillnet gear may prevent additional closures in the future and would result in positive ecological impacts to endangered Atlantic right whales.

Mandatory workshops for HMS gillnet vessel owners and operators could increase the likelihood of the safe release of the rarely encountered and endangered smalltooth sawfish. In the case of the one observed interaction with gillnet gear and the smalltooth sawfish, the sawfish was cut from the net and released alive with no visible injuries (Carlson and Baremore, 2003). If the entangled gear is sacrificed, smalltooth sawfish can be removed safely. The workshops would inform owners and operators that smalltooth sawfish are listed as an endangered species, enable them to identify the species, and educate them on the safe-handling and release techniques to reduce potential sawfish mortalities occurring as a result of encounters with gillnet gear.

An additional ecological benefit of training the vessel owners and operators on the safe handling and release techniques for gillnet fishing gear is to potentially reduce the mortality of non-target species, such as red drum, manta and cownose rays, king mackerel, great barracuda, billfish, and little tunny. This alternative would likely benefit non-target species by increasing post-release survival of all species discarded.

Alternative A6, a preferred alternative, considered several different timetables for renewing the workshop certification under alternative A6 (*e.g.*, two, three, or five year timetable). The Agency may also consider additional recertification options in the future as new information arises related to safe handling and release of protected resources. Requiring renewal of mandatory workshop certification every two years would likely have slightly positive ecological impacts. NMFS assumes that participants engaged in a hands-on, day-long, workshop that requires participants to pass a practical examination demonstrating proficiency at the culmination of the workshop would maintain familiarity with the protocols for a reasonable period of time afterward. All new participants in the fishery would still be required to attain certification before being able to attain their permit and permit holders would need to renew their certification within two years of their original attendance to maintain an HMS permit.

Requiring re-certification every three years may have slightly less positive ecological impacts than every two years. Recertification every three years is a reasonable frequency to ensure that participants are kept abreast of the safe handling and release protocols and to also maintain awareness of new research and development related to workshop curricula. Permit holders would be required to recertify every three years before being able to renew their shark, swordfish, or tuna permits that allow the use of longline or gillnet gear.

Requiring re-certification every five years would likely have less positive ecological impacts than the two previously mentioned timeframes. Recertification every five years would allow a more time to lapse between certification workshops than necessary to maintain proficiency and provide updates on research and development of handling and dehooking protocols. These impacts may be mitigated somewhat by also selecting alternative A3 (certification for operators) or A4 (certification for owners, operators, and crew) which ensures that both operators and vessel owners are certified, thereby, increasing the number of fishery participants who interact with sea turtles and/or other protected species and are aware of how to safely handle and release them.

NMFS received several comments in support of alternative time periods for renewal of certification; however, the Agency prefers to maintain the original preferred alternative of recertification every three years. NMFS would require owners and operators of HMS longline and shark gillnet vessels to renew the mandatory workshop certification every three years. A three year period for recertification would likely maintain proficiency in the release, disentanglement and identification protocols, and allow NMFS to update owners and operators on new research and developments related to the subject matter while not placing an excessive burden on the participants (*e.g.*, lost fishing time and travel to attend workshops).

*Social and Economic Impacts*

Under alternative A1, there may be some negative economic impacts, related to protected species safe handling, release, and identification workshop travel costs and lost fishing time, which may be incurred by fishery participants who choose to attend; however, the travel costs and lost fishing time for participants attending the voluntary workshops are discretionary, and not mandatory. In addition to the participant cost, there is an Agency cost associated with the implementation of these workshops as well. Determining the Agency cost for holding these workshops is somewhat uncertain because no decision has been made on the instructors, locations, curriculum, or materials for the course. Based on the voluntary workshops held in 2005, NMFS estimates that one protected species workshop would cost about $3,500. The hands on training component would limit the number of participants in each workshop to a maximum of about 48 people. Due to the voluntary nature of alternative A1, it is uncertain how many workshops would be held. If one workshop were held each month, then the Agency cost would be about $42,000 per year. In addition to running the workshops, materials would need to be developed and reproduced for distribution at these workshops. Because the materials have not yet been developed, this aspect of the Agency cost is unknown at this time.

Voluntary workshops hosted by NMFS or industry may be viewed more favorably by the affected public than mandatory workshops; however, past experience has shown that these workshops are generally not well attended. Poor attendance, and the resulting impact on post-release mortality of threatened and endangered species, may hinder achieving the targets issued for protected resources due to lack of proficiency with the dehooking techniques and equipment on the behalf of the participants. Failure to achieve the target post-release mortality rates may result in future time/area closures as specified in the BiOp, including a closure of the entire Gulf of Mexico, which would result in extensive negative social and economic impacts to the pelagic and bottom longline fisheries. Voluntary workshops may improve communication between constituents and the Agency and would improve awareness of Agency actions.

Alternatives A2 - A4 would also likely result in some negative economic and social impacts, as a result of traveling to the protected species safe handling, release, and identification workshops and the fact that lost fishing time may be incurred by participants that would be required to attend these mandatory workshops. In order to provide fishermen and vessel owners time to prepare for economic costs associated with this mandatory requirement, owners and operators would have until their permit expires in 2007 to obtain the workshop certification.

Additionally, the Agency will strive to host a number of workshops in regional fishing hubs to minimize travel and lost fishing time. The workshops would be held during periods when the fishery is typically inactive, effectively minimizing lost fishing time to the extent practicable. For example, the workshops may be held when the fishery is closed and prior to the start of the next trimester for sharks. However, since the Agency does not know what other fisheries fishermen may be participating in, the Agency cannot guarantee that all workshops will be held at appropriate times to minimize all lost fishing opportunities. The timing and location of these workshops should lessen the negative social and economic impacts of taking the time away from fishing, work, or other responsibilities. While these alternatives would have an economic impact to the industry, these impacts may be mitigated by the benefits associated with increased industry education (*i.e.*, increased compliance, skills, and stewardship). These alternatives could result in some social benefits.

NMFS conducted an opportunity cost analysis to determine the economic costs associated with attending the various workshop alternatives. This analysis utilized the economic information gathered in the PLL Logbook, and in particular the information in the economic costs section that is required to be completed by selected vessels. For the vessels that completed the economic portion of the PLL Logbook in 2004, revenues per trip were estimated by taking the number of fish caught per trip, multiplying the number of fish by average weight for each species harvested, and multiplying the total weight for each species by average prices for each species as reported in the dealer landings system. The costs reported for each trip were then subtracted from the estimated revenue for each trip. Then the number of days at sea, as reported in logbooks, was used to determine the average net revenue per day at sea for each trip taken. Finally, the information provided on crew shares was used to allocate the net revenue per day at sea to owner, captain, and crew. The BLL cost earnings data set is limited compared to the PLL cost earnings data in the HMS Logbook, therefore, the sample size is not as significant for BLL trips. Information from the HMS permits database was then used to estimate the potential number of participants in each of the workshop alternatives. Since information on the number of operators per permitted vessel was not available, NMFS conservatively estimated that there could be two operators per permit for PLL vessels, and one captain for all others. Net revenues per day for owners, operators, and crew was then multiplied by the number of participants expected for each workshop alternative to estimate the opportunity cost for a one day workshop. The economic impacts (*i.e*., out of pocket cash costs) associated with attending workshops is likely to be less than the economic opportunity costs estimated since NMFS intends to schedule workshops on less productive fishing days to avoid lost time at sea.

As of February 2006, there are about 549 vessel owners permitted to fish for HMS with pelagic and bottom longline gear, which would be the estimated number of participants included in the workshops for alternative A2. According to an analysis of 2004 cost-earnings information as reported in HMS logbooks, the median opportunity cost for individual, bottom and pelagic longline vessel owners to participate in a one-day workshop would be \$281 and \$448, respectively. Alternative A3 would apply to vessel operators. NMFS assumed there are approximately two operators per vessel owner (permit), resulting in a total of 1,098 participants. According to the cost-earnings analysis mentioned above, the median opportunity cost for individual, bottom and pelagic longline vessel operators to participate in a one-day workshop would be \$345 and \$149, respectively. Alternative A4 would include vessel owners, operators, and crew. Based on logbook data, an estimated average of four crewmembers is associated with any particular vessel. These workshops would have 3,843 participants, thus, alternative A4 would have the largest economic impacts. According to the cost-earnings analysis mentioned above, the median opportunity cost for individual, bottom, and pelagic longline vessel crewmembers to participate in a one-day workshop would be $90 and $109, respectively. These individual costs when added to the individual opportunity costs of owners and operators, results in a combined individual opportunity cost of $716 for bottom longline fishery participants and $706 for pelagic longline fishery participants to participate in a one-day workshop. These opportunity cost estimates should be considered upper bounds on the potential economic costs associated with attending workshops. Information quantifying the economic value of time spent at the workshops is not currently available to further refine the upper bound cost estimates used in the economic analysis of workshop alternatives. Additional information regarding economic impacts for each of these alternatives can be reviewed in Chapter 6.

The cost to the Agency varies for each of these alternatives due to the number of people that would be required to attend and achieve the workshop certification. Alternative A2 calls for at least 549 workshop participants. If each workshop can accommodate 45 people, then a minimum of 12 workshops would need to be held. At a cost of $3,500 per workshop, alternative A2 has an Agency cost of about $42,000 plus the cost of outreach materials. Alternative A3 requires 1,098 owners and operators to obtain the workshop certification. The Agency would need to hold about 23 workshops at a total cost of $80,500 plus materials. Alternative A4 requires 3,843 owners, operators, and crew members to obtain a workshop certification; therefore, the Agency would need to hold at least 81 workshops at total cost of $283,500 plus materials. The greater the number of people certified, the greater the number of copies that need to be made for the outreach materials.

Under alternative A5, shark gillnet vessel owners and operators would be required to attend workshops discussing safe release and disentanglement protocols, protected resources identification, and current regulations. The administrative costs for workshops are high, but may be mitigated by the benefits associated with increased industry education (*i.e.*, increased compliance, skills, and stewardship). This alternative would likely result in social benefits. On February 14, 2006, NMFS issued a temporary rule that banned the use of all gillnet gears in the Atlantic Right Whale Calving Area until March 31, 2006, because of a right whale calf that interacted with gillnet gear on January 22, 2006. A closure results in a negative economic impact to the fishery. Dissemination of information related to release and disentanglement of marine mammals from gillnet gear may prevent additional closures in the future.

The costs incurred by vessel owners and operators would be related to travel and time to attend the workshop, resulting in out of pocket expenses and lost opportunity costs. NMFS estimates that there are approximately 20 participants in the shark gillnet fishery that would attend workshops; 80 percent of the identified shark gillnet permit holders and operators are located in Florida, and 20 percent are in North Carolina and New Jersey. As mentioned earlier, NMFS conducted an analysis of 2004 cost-earnings information as reported in HMS logbooks. Individual opportunity costs are not available for gillnet vessel owners and operators due to confidentiality concerns, however the median opportunity cost for vessel owners and operators of all gear types combined, including gillnets, to participate in a one-day workshop would be

$578 ($424 owner's share plus $154 captain's share). Additional information regarding economic impacts of this alternative can be reviewed in Chapter 6. To minimize cost to the owners and operators, NMFS would offer workshops in the areas where the shark gillnet fishery participants are located. Workshops would be held during periods when the shark gillnet fishery is typically inactive, effectively minimizing lost fishing time to the extent practicable. For example, the workshops may be held when the fishery is closed and prior to the start of the next season. However, the Agency does not know what other fisheries the fishermen may be participating in when the shark gillnet fishery is closed. The timing and location of these workshops should lessen the negative social and economic impact of taking time away from fishing, work, or other responsibilities. Additionally, owners and operators would have until the vessel's HMS permit expires in 2007 to receive the workshop certification. This delayed effectiveness would provide fishermen and vessel owners with time to prepare for economic costs associated with this mandatory requirement.

While there are only 20 participants associated with alternative A5, the participants are spread out between Florida, North Carolina, and New Jersey. To reduce the burden to the industry, three workshops would need to be held, which would cost the Agency about $10,500. If the all three preferred alternatives A2, A3, and A5 are considered together, the Agency would likely hold at least one workshop in Florida, North Carolina, and New Jersey, which could accommodate the additional 20 participants associated with the gillnet fishery. The Agency cost for all three workshops would be about $126,000 plus the cost of materials.

Most trades and professions require practitioners to obtain licenses demonstrating competence; however, there is still an economic opportunity cost associated with any required activity that would not otherwise be taken voluntarily. When analyzing the economic costs associated with workshop alternatives, the next best activity that workshop participants would be engaged in would be fishing. In the economic literature, it is common practice to use wage rates from primary job activities as the opportunity cost of engaging in other activities.

Workshop attendance may increase the time spent away from family, particularly if the workshops are scheduled during the fishery's downtime. Because the workshops would be scheduled where the permit holders are located in significant concentrations, attending the workshop should not take more than a day to a day and a half away from their family, responsibilities, or other fishing activities. The owners and operators would benefit from participating in the workshop by advancing their knowledge and skills in their industry. The training provided by workshops would be valuable to fishermen and could offset some unquantifiable portion of the estimated opportunity costs.

These workshops would provide a forum for discussion and education. The vessel owners and operator would have an opportunity learn about the latest advances in safe release and disentanglement protocols, as well as protected species identification and the latest regulations pertaining to their fishery. This knowledge also translates into a skill that could be used to increase operators' bargaining position for employment. Finally, these workshops are a dedicated opportunity for the Agency to interact and communicate with the industry.

Recertification every two years would likely have the greatest economic impact on participants; however, the extent of the impacts would depend on the mechanism for recertification: in-person workshops versus the use of alternative sources of media including CD-ROM, DVDs, or web-based media that would not result in travel costs or lost fishing time. The Agency will consider ways to moderate the cost involved with recertification for all of the alternatives considered. The potential economic impacts of having to get recertified in-person would increase proportionately as the number of participants increase. Certifying the participants every five years would result in the least negative economic impacts to the fishing community because potentially it would result in the most infrequent recertification schedule. If in-person recertification workshops were selected, travel costs, and lost fishing time would be minimized.

Under the preferred alternatives, the Agency cost to recertify all HMS longline and gillnet owners and operators every three years is difficult to estimate. Every three years, there would likely be a large pulse of individuals that would need to be recertified in order for the owners to renew their HMS permits. In these years, the Agency cost may be similar to the initial year. During the interim years, there may be an unquantifiable number of new entrants to the fishery or latent permit holders that would need to be certified. Because the number of individuals is unknown, it is difficult to determine the number of workshops that would be needed. At a minimum, one workshop each month would be held at total cost of $42,000 per year plus materials.

A recertification frequency of three years would allow for sufficient retraining to maintain proficiency and update fishermen on new research and development related to the subject matter while not placing an excessive economic burden on the participants due to lost fishing time and travel resulting from attending a recertification workshop in person.

*Conclusion*

Mandatory protected species safe handling, release, and identification workshops for PLL, BLL, and gillnet vessel owners and operators would result in positive ecological impacts by reducing the mortality of protected resources. These workshops are essential for complying with BiOp requirements by reducing the post-release mortality of sea turtles and other protected resources. Workshop certification would be linked to the renewal of the vessel's permit, ensuring well attended workshops. Requiring certification for vessel operators would guarantee at least one person on board the vessel during fishing activities trained in the safe handling and release protocols. Educating vessel owners and operators on the proper identification of protected resources would enable them to apply the appropriate safe handling and release protocols, improve compliance with regulations, and enhance the utility of vessel logbook data. To the extent that interactions cannot be avoided, the safe handling and release workshops should result in increased survival rates of protected resources hooked or entangled by HMS fishing gears. None of the alternatives considered for workshops on safe release, disentanglement, and identification of protected resources are expected to have any impacts on EFH. The one-day workshops are not expected to result in excessive economic impacts as they would be scheduled at numerous locales along the Atlantic coast, minimizing travel, lost fishing time, and other opportunity costs. The Agency would delay the workshop certification deadline to facilitate the attendance of owners and operators. Requiring that owners and operators in longline and gillnet fisheries to recertify every three years would balance the ecological benefits of maintaining familiarity with the protocols and the economic impacts of workshop attendance due to travel costs and lost fishing opportunities. Owners and operators of longline and gillnet vessels would be required to recertify every three years in an effort to maximize ecological benefits and minimize economic impacts of attending workshops.

#### *4.1.1.2 HMS Identification Workshops*

The purpose of HMS identification workshops is to enhance the ability of individuals involved in the HMS fisheries to identify sharks at the species level. Participants who successfully complete the workshops would receive a multi-year certification, which would serve as proof that the participant has completed the necessary training. To the extent practicable, these workshops would be open to other interested individuals (*e.g*,, individuals participating in the shark fishery, port agents, law enforcement officers, and state shark dealers) on a voluntary basis, but mandatory for Federally permitted shark dealers.

Accurate species identification is important for compliance with HMS fishery regulations, including the avoidance of prohibited species, maintaining quota limits, and accurate data collection. Species data collected on vessels and by dealers are entered into vessel logbooks and dealer reports, and are used to establish and monitor quotas and for stock assessments. It is important that fishery scientists and managers have the most reliable data possible for assessing the status of stocks and for formulating appropriate fishery management strategies based on this information, both to prevent overfishing and to rebuild those stocks that are already overfished. However, a large proportion of commercially landed sharks are reported as "unclassified" (*i.e*., unidentified), creating gaps in data collection in terms of actual species. As shown in Tables 3.40, 3.41, and 3.42, 19 percent of total 2004 LCS landings were unidentified, 0.3 percent of total 2004 SCS landings were unidentified, and 53 percent of the pelagic shark landings were unidentified. Of the total 2004 shark landings, 71 percent were unclassified shark species. Species identification workshops could reduce this problem by improving species specific reporting, thereby enhancing the quality of the data used in setting quotas and for stock assessments.

As described in Chapter 2, the alternatives considered for conducting species identification workshops are:

A7 No HMS identification workshops (No Action)

A8 Voluntary HMS identification workshops for dealers, all commercial vessel owners and operators, and recreational fishermen

*A9 Mandatory shark identification workshops for all shark dealers – Preferred Alternative*

A10 Mandatory HMS identification workshops for all swordfish, shark, and/or tuna dealers

A11 Mandatory HMS identification workshops for all commercial longline vessel owners

A12 Mandatory HMS identification workshops for all commercial longline vessel operators

A13 Mandatory HMS identification workshops for all commercial vessel owners (longline, CHB, General category, and handgear/harpoon)

A14 Mandatory HMS identification workshops for all commercial vessel operators (longline, CHB, General category, and handgear/harpoon)

A15 Mandatory HMS identification workshops for all HMS Angling permit holders

*A16 HMS identification certification renewal (every 3-years) – Preferred Alternative*

*Ecological Impacts*

Under alternative A7, the No Action alternative, NMFS would continue to make available for purchase the HMS identification manual, *Guide to Sharks, Tunas, & Billfishes of U.S. Atlantic & Gulf of Mexico*, and distribute wheelhouse placards at no cost, as well as other related educational materials. Although these materials enhance fishery participants' ability to identify HMS commonly caught in U.S. fisheries, discerning subtle identification features using these materials is less effective compared to hands-on workshops, particularly when attempting to distinguish species that are similar in appearance (*e.g.*, certain sharks). Furthermore, this guide does not contain pictures or information that may be beneficial for HMS carcass identification, which is generally how the catch is offloaded to HMS dealers. Also, there is no assurance that fishery participants will utilize or fully understand the materials distributed. As species identification data is entered into fisheries logbooks and dealer reports, which are used in quota monitoring and in preparing stock assessments, identification inaccuracies could be reflected in the resulting quotas and assessments, thereby affecting associated fishery management strategies.

Implementing voluntary workshops under alternative A8 could provide some ecological benefits, provided fishery participants attend the voluntary workshops. In the past, however, voluntary workshops conducted by NMFS have not been well attended, and could also be the case if future identification workshops are voluntary. The hands-on approach of workshops would enhance understanding of identification features so that those who do attend would be better able to identify HMS and thus provide more accurate information in logbooks and dealer reports. This, in turn, could provide some level of improvement in the accuracy of data used for quota monitoring and stock assessments. In addition, those who attend and gain a better understanding of identification features would be in a better position to comply with fishery regulations, such as identifying prohibited species. All of these factors would indirectly contribute to stock rebuilding efforts and, therefore, result in positive ecological effects on HMS fishery resources.

Under alternative A9, a preferred alternative, HMS identification workshop attendance and certification would be required for all Federally permitted shark dealers by December 31, 2007, with successful completion and mandatory recertification linked to the dealer's ability to obtain and renew their Federal dealer permit. Mandatory attendance by shark dealers is the preferred alternative because: (1) a single dealer must identify offloaded catches from a number of vessels, involving not only large numbers of fish but many different species of fish, as well; (2) not only are some shark species difficult to distinguish from one another, but dealers need to identify fish that have been dressed, making accurate identification even more difficult; and, (3) while both logbook and dealer data are used for stock assessments, the dealer is ultimately responsible for identifying the sharks, and their data is used for both quota monitoring and stock assessments. Additionally, sharks on the prohibited species list are not to be purchased by shark dealers. The shark identification workshops would improve dealer identification of prohibited species, leading to the reduction of the number of prohibited species landed and purchased. Without a market for prohibited shark species, shark fishermen would have greater pressure to correctly identify sharks at the species level and land more non-prohibited sharks. The identification workshops would help reduce the number of prohibited sharks landed and possibility differentiate between SCS and LCS, thus facilitating dealer compliance with preferred alternatives, I3b, to make it illegal for dealers to purchase sharks in excess of the 4,000 pound LCS retention limit. With accurate shark identification, there may be a better understanding of shark bycatch in the fleet.

The Agency received comment regarding the need for proxies; flexibility in certifying newly hired proxies, and the need for multiple proxies. Shark dealers would be encouraged to send as many proxies as is necessary to train the individuals responsible for shark species identification within the dealer's business. As all permitted dealers may not be geographically located where vessels unload their catches, a proxy could attend the workshop to allow the permitted dealer to meet mandatory attendance requirements. If a dealer opts to send a proxy, then the dealer would be required to designate a proxy from each place of business covered by the dealer's permit. A proxy would be a person who is employed by a place of business, covered by a dealer's permit, a primary participant in identification, weighing, or first receipt of fish as they are offloaded from a vessel, and involved in filling out dealer reports.

Public comment on the HMS Identification Workshops were supportive of mandatory workshops for Federally permitted shark dealers, but also suggested that these workshops be available to others, such as the recreational and commercial fishery, law enforcement, port agents, and state shark dealers. While these workshops would be mandatory for Federally permitted shark dealers, NMFS will accommodate other interested individuals when it is feasible. The ecological benefits of alternative A9 would be similar to those described in alternative A8, voluntary workshops, but would be expanded in magnitude, as a greater number of individuals would be trained in identification, thereby substantially improving the accuracy of data entered into dealer reports. Mandatory workshops for shark dealers, in turn, would contribute to improved stock assessments, quota monitoring, and stock rebuilding efforts.

Under alternative A10, mandatory HMS identification workshops and certification would be required not only for shark dealers, but for swordfish and tuna dealers as well. Benefits of this alternative are that training would be increased to include additional participants compared to only including shark dealers, in which case training would include identification of commercially fished HMS as well as sharks. Although ecological benefits would be similar to those described under alternative A9, they would be expanded to include other HMS fisheries, and would likely result in greater ecological benefits. As with alternative A9, a proxy could attend the workshop in order for the dealer to meet mandatory attendance requirements.

Under alternative A11, HMS identification workshops and certification would be required for vessel owners issued limited access permits and using pelagic or bottom longline gear during fishing operations. Workshop completion and mandatory periodic recertification would be tied to Federal shark dealer permit issuance and renewal. Training of vessel owners could serve to improve species data entry in vessel logbooks, but only if owners are on board the vessel. In some cases, the vessel owner may not be the vessel operator, and thus not involved in daily fishing activities or be available to identify catches. Because of the potentially limited involvement of longline vessel owners in the vessel's fishing activities, ecological benefits would likely be narrower in scope than expected under alternatives A8, A9, and A10.

Under alternative A12, HMS identification workshops would be required for all commercial pelagic or bottom longline vessel operators. Ecological benefits to the fisheries, although similar in nature to those expected under alternative A11, would be expanded in magnitude, because operators are more actively involved in fishing activities and fish identification. This would result in increased accuracy of species-specific data reported in logbooks. Ecological benefits would be similar in nature as described for the alternatives above, resulting in improved stock assessments and indirect benefits to stock rebuilding.

Under alternative A13, attending HMS identification workshops and obtaining a certification in HMS identification would be required for all HMS permitted commercial fishing vessel owners. Participants who have more than one permit would only be required to attend one workshop. Successful workshop completion and mandatory periodic recertification would be tied to the issuance and renewal of Federal HMS permits. Under this alternative, training and identification accuracy would be significantly expanded in magnitude beyond that conducted under alternatives A8 through A12. However, this alternative would only improve species data entered into reports if the owners are on board the vessel, involved in daily fishing activities, and available to identify fish landed. Given that in many cases the vessel owner is the operator aboard the vessel during fishing activities, ecological benefits to HMS fishery resources could be expanded beyond that expected under the other alternatives listed above, resulting in increased indirect benefits to stock rebuilding.

Under alternative A14, mandatory HMS identification workshops and certification would be required for all HMS permitted commercial fishing vessel operators. For the CHB, General category, and handgear/Harpoon categories the Agency assumes that the vessel owners (permit holders) are also the primary operators. Participants who are operators on multiple vessels fishing under different permits would only be required to attend one identification workshop. Due to the large number of participants, training and identification skills would be significantly expanded beyond that under the other alternatives, resulting in a greater indirect benefit to HMS fishery resources. This includes an improvement over alternative A13, as well, since in all cases it can be expected that the vessel operator is on board the vessel, involved in daily fishing activities, and available to identify catches. Therefore, training of all commercial vessel operators could serve to significantly improve species data for fishing activities that are required to submit a logbook and thereby improve the basis for quotas and stock assessments, as well as regulatory compliance. Accordingly, ecological benefits to HMS fishery resources would also be expanded beyond that expected under the previous alternatives, as a result of more accurate species catch data, and improved regulatory compliance.

Under alternative A15, mandatory HMS identification workshops and certification would be required for all HMS Angling category permit holders. The number of individuals trained would be significantly greater than under the other alternatives, resulting in potentially greater positive ecological benefits for HMS fisheries. NMFS received public comment in support of

HMS identification workshops for the angling community; however, this alternative does not resolve the data quality issues associated with commercial vessel logbooks and dealer reports. Thus, quota monitoring, commercial regulatory compliance, and stock assessments would not benefit as they would under the other alternatives.

Alternative A16 requires HMS identification workshop certification renewal every three years. The Draft Consolidated HMS FMP considered and analyzed three timetables for certification renewal - two, three, or five-year timetables. NMFS assumes that participants engaged in a hands-on, day-long workshop that requires participants to pass a practical examination demonstrating proficiency at the culmination of the workshop would maintain familiarity with identification protocols for a reasonable period of time afterward. All new entrants/owners into the fishery would still be required to obtain HMS identification workshop certification before acquiring the Federal HMS permit, and permit holders would need to renew their certification within three years of their prior attendance to maintain an active Federal HMS permit. Requiring renewal of workshop certification every two years would likely have the most positive ecological impacts. Requiring re-certification every three years would have somewhat less positive ecological impacts. Requiring re-certification every five years would likely have the least positive ecological impact, as this would allow a more extensive period of time to lapse between certification workshops than may be necessary to maintain species identification proficiency. Requiring workshops recertification every three years strikes a balance between ecological benefits and economic costs.

*Social and Economic Impacts*

Under alternative A7, the No Action alternative, the social and economic impacts would not change, positively or negatively, primarily because current activities related to the dissemination of information to assist in identifying HMS would remain the same. Alternative A7 would not have any additional Agency costs as it is the No Action alternative.

Under the remaining alternatives, the identification workshops would serve an educational purpose and as a forum where the industry could also exchange information about their business. This atmosphere could provide attendees with more information about their fisheries and create a forum for participants to express their comments regarding fisheries management and regulations. This communication could lead to better working relationships with the Agency.

Under alternative A8, voluntary HMS identification workshops, there would be neither positive nor negative social and economic impacts, primarily because attendance would be voluntary and at the convenience of the participants. For those who do attend, there would be some social benefit related to sharing of fishery information. Any associated travel costs would be minimal, as it is not likely that participants would go to substantial expense and trouble for this type of voluntary training. In the past, voluntary workshops conducted by NMFS have not been well attended, and this could also be the case if identification workshops are voluntary.

The voluntary nature of the workshops proposed in alternative A8 makes it difficult to estimate the number of individuals that would attend the workshops. As with the protected species workshops, the number of workshops held is driven by the number of participants with the maximum being 30 people and the location of the individuals. Determining the Agency cost for holding these workshops is also uncertain at this time because the instructors, locations, curriculum, and materials have not yet been determined. At this time, the NMFS estimates one HMS identification workshop to cost about $2,100 including the cost of outreach materials and staff time. If the Agency held one workshop per month, the Agency cost associated with alternative A8 would be $25,200.

Under alternatives A9 through A15, social and economic impacts would be similar in nature, the main difference being the number of attendees and the associated overall total costs, taking all individuals into consideration. On an individual basis, the costs anticipated to be incurred by fishermen would be those related to travel and time to attend the workshops, resulting in out of pocket expenses and lost opportunity costs. Alternative A9 would require that approximately 336 shark dealers attend mandatory workshops, alternative A10 would also require tuna and swordfish dealers to attend, raising the total to 1,037 dealers. Daily opportunity cost estimates for dealers are not currently known. Alternative A11 would require approximately 549 pelagic and bottom longline vessel owners to participate in identification workshops, resulting in an individual opportunity cost ranging between $448 (median pelagic longline owner's share) and $281 (median bottom longline owner's share) per day. Alternative A12 would include longline vessel operators. With 549 permitted vessels and an estimated two operators per vessel, alternative A12 would call for about 1,098 participants in addition to the owners (1,647 total). This estimated number of operators may be an overestimate because some owners also operate the vessel, and not all vessels have two operators. Alternative A12 would result in an individual opportunity cost ranging between $149 (median pelagic longline captain's share) and $345 (median bottom longline captain's share) per day. Alternative A13 would include all commercial HMS owners (longline, CHB, General category, and handgear/harpoon) and would require approximately 9,636 participants to attend mandatory workshops. This alternative would result in an individual opportunity cost of $424 (median owner's share for all gear types combined). Daily opportunity cost estimates for CHB owners are not currently known. Alternative A14 would include operators of commercial HMS vessels. Alternative A14 would have an additional 1,098 participants as the Agency estimates two operators per vessel in the longline fisheries for a total of 10,374 operators. Alternative A14 would result in a combined opportunity cost of $578 (median owner's share $424 plus median captain's share $154 for all gear types combined). Daily opportunity cost estimates for CHB owners/operators are not currently known. Alternative A15 would require all HMS Angling permit holders to attend workshops, which is the largest single category of HMS permit holders, including approximately 25,238 participants. Daily opportunity cost estimates for HMS Angling permit holders are not currently known. Additional information regarding economic impacts of these alternatives can be reviewed in Chapter 6.

To minimize costs to fishermen, NMFS intends to offer workshops at a variety of locations near high concentrations of dealers, according to the addresses listed on the permits. NMFS would also try to hold workshops during off-peak times to minimize interruption to the businesses. However, since the Agency does not know what state fisheries dealers may be involved with, the Agency cannot guarantee that all workshops will be held at appropriate times to minimize all lost opportunities. Further, the requirement to obtain workshop certification would be delayed until December 31, 2007, to provide dealers more time to prepare for the economic costs associated with this mandatory requirement. The administrative costs to NMFS for the workshops is high, but may be exceeded by the benefits associated with the possible impacts from increased education. Before implementation, NMFS would attempt to identify ways to minimize costs to attendees as much as possible.

As with the protected species workshops, the Agency cost will vary depending upon the number of participants required to obtain a workshop certification. Alternative A9, the preferred alternative, requires the attendance of all Federally permitted shark dealers, which is about 336 individuals, plus any additional proxies involved with shark identification. At a minimum the Agency would need to hold 12 workshops, accommodating a maximum of 30 people per workshop. At a cost of $2,100 per workshop, 12 workshops would cost the Agency an estimated $252,000. Alternative A10 would require all Federal HMS dealers or about 701 individuals to be workshop certified; holding 24 workshops would cost the Agency about $50,400. Alternative A11 would certify 549 commercial longline vessel owners at about 19 different workshops for an Agency cost of $39,900. To certify all commercial longline operators (alternative A12), the Agency would need to hold about 37 workshops with an estimated Agency cost of $77,700. Expanding the universe of certified individuals in alternative A13 to all commercial HMS permit holders would require at least 322 workshops and the Agency cost would be about $676,200. The Agency would need to hold at least 346 workshops to accommodate all 10,374 commercial HMS operators. Alternative A14 would have an estimated Agency cost of $726,600. The largest number of individuals would be certified under alternative A15 with 25,328 Angling permit holders. This alternative would cost the Agency an estimated $1,768,200.

Alternative A16 has a range of social and economic impacts depending on the frequency of recertification workshop attendance. In the Draft Consolidated HMS FMP, NMFS considered requiring the workshop certification renewal every two, three, or five years. The two additional years of a five-year timetable may compromise dealer proficiency in shark identification and may have greater economic impacts to dealers because of the expense of one-on-one training, as well as the cost of travel to the trainer location. In an effort to reduce economic impacts to shark dealers, the schedule for HMS Identification Workshops would be available in advance to allow dealers to select workshops close to them and most convenient to their schedule. If a dealer and/or proxy is unable to attend a scheduled workshop, NMFS will consider granting one-on-one training at the expense of the dealer. The Federally permitted shark dealer would be held accountable for ensuring that the appropriate individuals receive the required training in shark identification. The attendance of multiple proxies per shark dealer may ensure that the dealer has at least one certified staff member and the skills to properly identify sharks if another certified employee is terminated. According to public comment, NMFS should anticipate turnover in dealer proxies. These one-on-one training sessions would accommodate the replacement of a proxy whose employment was terminated on short notice, but, again, these sessions would be at the expense of the permit holder. If dealer employee turnover is high and the renewals are scheduled every five-years, a dealer may pay for a greater number of one-on-one training sessions than with a three-year timetable.

In addition to the frequency, economic impacts would be dependent on the type of recertification selected by the Agency, such as hands-on, in-person or training via the Internet, DVD, and/or printed materials. In the future, the Agency intends to investigate the use of alternative media to train shark dealers and/or renew the shark identification workshop certification, however the initial training would be in-person and hands-on. If NMFS does transition to Internet training, the Agency will look at the option of making any online training available to all interested parties. Hands-on, in-person recertification workshops would result in additional travel costs and lost fishing time. To the extent possible, NMFS would schedule recertification workshops so as to minimize these factors, but the negative economic impacts would be greater for hands-on, in-person recertification due to more frequent travel costs and potential increased fishing down time.

Under the preferred alternative, to recertify every three years, there would likely be a large pulse of individuals seeking to be recertified every three years when certificates expire. In these years, the Agency cost may be similar to the initial year as discussed above. During the interim years, there may be an unquantifiable number of new entrants to the industry or business or latent permit holders that would need to be certified. Because the number of individuals needing the workshop certification in the interim years is unknown, it is difficult to determine the number of workshops that would be needed. At a minimum, one workshop each month would be held at total annual cost of $25,200.

*Conclusion*

Alternative A9, mandatory workshops for all Federally permitted shark dealers, is the preferred alternative because species-specific identification of offloaded shark carcasses is much more difficult than for other HMS as evidenced by the large proportion of “unclassified” sharks listed on shark dealer reports. This uncertainty compromises quota monitoring and stock assessment efforts. Dealers are a focal point for gathering shark landings information as sharks from numerous vessels are offloaded at each individual dealer. Positive identification is often less difficult for fishermen than dealers as they know exactly where (depth, type of habitat, etc) a shark has been caught and often see the sharks alive and intact. These workshops would be open to other interested individuals (*e.g.,* individuals participating in the shark fishery, port agents, law enforcement officers, and state shark dealers) on a voluntary basis, but would be mandatory Federally permitted shark dealers. Federally permitted shark dealers would be required to receive this training in an effort to reduce unclassified shark landings and improve species-specific landings data. Improvements in shark dealer data could improve the existing quota monitoring program, as well as future stock assessments. The HMS identification workshops are also not expected to have any impacts on EFH. Additionally, these workshops are not expected to alter existing fishing effort or practices, and therefore, should not result in increased interactions with protected resources. The Agency would attempt to minimize economic impacts to shark dealers by delaying the date of effectiveness until January 1, 2007, meaning shark dealers would need to be certified by December 31, 2007. Additionally, workshops would be held at fishing ports to minimize travel costs and during non-peak fishing times to minimize perturbations to business activity, to the extent possible. Based on the Draft Consolidated HMS FMP analyses and public comment, the Agency has determined that the HMS identification workshop certification for all Federally permitted shark dealers would be most appropriately renewed on a three-year timetable. Recertification every three years is a reasonable frequency to ensure that participants are kept abreast of identification protocols.

### 4.1.2 Time Area Closures

NMFS considered alternatives ranging from maintaining existing closures (No Action) to a complete prohibition of pelagic longline (PLL) gear in all areas in order to reduce the bycatch and bycatch mortality of non-target HMS and protected species, such as sea turtles, in Atlantic HMS fisheries. While NMFS primarily focused on pelagic and bottom longline gear in this section, other gear types and other approaches to reduce bycatch and bycatch mortality are considered in other sections (*e.g.,* Workshops in Section 4.1.1.1; restrictions on recreational gears in Section 4.2.3). Alternatives B4 (complementary closures in Madison-Swanson and Steamboat Lumps) and B5 (criteria to use when implementing or modifying area closures) are the preferred alternatives. The No Action alternative (B1) is shown in Figure 4.1. Alternatives B2(a) through B2(e) are shown in Figure 4.2. Alternatives B3(a) and (b) are shown in Figure 4.3. and alternatives B4 and B6 area shown in Figure 4.4 and Figure 4.5.

The alternatives were grouped according to the primary objectives of the time/area closure. Alternatives B2(a) through B2(e) consider new closures for PLL gear to primarily address white marlin, bluefin tuna (BFT), and sea turtle bycatch. Alternatives B3(a) and B3(b) consider modifying existing closures for PLL gear. Regardless of the grouping, bycatch of non-target species and protected species, such as sea turtles, was taken into consideration for all of the alternatives. Alternatives B4 through B7 consider either complementary measures, criteria for time/area closures, closures for bottom longline (BLL) gear, or complete closure of the HMS PLL fishery. Several other alternatives, B2(f) – (k) and B3(c) – (d), were initially considered for new closures and modifications to existing closures but were not further analyzed (See Chapter 2 and Appendix A). Explanations of why certain alternatives were not further analyzed are included in Chapter 2, and tables summarizing data for each of the alternatives that were considered are included in Appendix A. The time/area closure alternatives considered are:

B1 Maintain existing time/area closures; no new time/area closures (No Action)

B2(a) Prohibit the use of PLL gear in HMS fisheries in the central portion of the Gulf of Mexico from May through November (7 months), annually

B2(b) Prohibit the use of PLL gear in HMS fisheries in an area of the Northeast during the month of June (1 month), each year

B2(c) Prohibit the use of PLL gear in HMS fisheries in the central Gulf of Mexico from April through June (3 months), annually

B2(d) Prohibit the use of PLL gear in HMS fisheries in the Gulf of Mexico west of 86 degrees W. Longitude year-round

B2(e) Prohibit the use of PLL gear in HMS fisheries in an area of the Northeast to reduce sea turtle interactions year-round

B3(a) Modify the existing Charleston Bump time/area closure to allow the use of PLL gear in all areas seaward of the axis of the Gulf Stream

B3(b) Modify the existing Northeastern U.S. time/area closure to allow the use of PLL gear in areas west of 72º 47’ W. Long. during the month of June each year

*B4* *Implement complementary HMS management measures in Madison-Swanson and Steamboat Lumps Marine Reserves year-round – Preferred Alternative*

*B5* *Establish criteria to consider when implementing new time/area closures or making modifications to existing time/area closures – Preferred Alternative*

B6 Prohibit the use of bottom longline gear in an area southwest of Key West to protect endangered smalltooth sawfish year-round

B7 Prohibit the use of PLL gear in HMS fisheries in all areas

*Ecological Impacts*

<u>Brief Summary of the Analyses for New Closures</u>

As described below, each of the alternatives would have varying degrees of ecological impacts. To help identify potential benefits and impacts of the various alternatives, NMFS conducted analyses using available data. These analyses are fully explained in Appendix A and a summary is provided below. Within this section, NMFS presents summary tables that were created to show the changes in the numbers of discards of white marlin, blue marlin, sailfish, spearfish, leatherback sea turtles, loggerhead sea turtles, other sea turtles, and BFT based on data from the Pelagic Observer Program (POP) (Table 4.4) or the Highly Migratory Species (HMS) Logbook (this is the logbook used by the PLL fleet) (Table 4.5) for the various time/area closure alternatives. In addition, individual tables for each of the alternatives are presented to show the monthly discards or landings of non-target or target HMS respectively, that include pelagic and large coastal sharks, and the percent reduction in numbers of hooks set. Data are also presented for the estimated change in targeted and retained catch of swordfish, bluefin, bigeye, albacore, yellowfin, and skipjack tunas (BAYS).

The analyses of the time/area closure alternatives utilized data from the POP, the HMS logbook, and the Commercial Shark Fishery Observer Program (CSFOP). Data from the observer program is referred to in the text as "observed," and data from the HMS Logbook is referred to as "reported" or "logbook" data. To determine the effectiveness of the current closures, NMFS compared data prior to implementation of the closed areas (1997 – 1999) with effort and catch data from 2001 – 2003 for various species. The analyses of the new time/area closures considered data primarily from the POP and HMS logbook from 2001 – 2003. Data from 2001 – 2003 were used because they include data after the most recent closures went into effect in 2000. For the alternatives considering modifications to existing time/area closures, NMFS compared data prior to implementation of the closed areas (1997 – 1999) for various species. In all cases, the POP and HMS logbook data were used to summarize monthly U.S. PLL catches throughout the operational range of the U.S. fleet in the Atlantic Ocean, Gulf of Mexico, and Caribbean (throughout the rest of this Section, the range of the PLL fishery is considered the Atlantic Ocean, Gulf of Mexico, and the Caribbean, although all three areas may not be explicitly referenced).

Complete, finalized data from 2004 were not available for the analyses presented in the Draft HMS FMP. Once the 2004 POP and HMS logbook data became available, NMFS conducted an analysis of a subset of the HMS logbook dataset from 2001 – 2004 (first six months of 2004 only) to determine whether there were any substantial differences from the 2001

– 2003 data presented in the Draft HMS FMP. NMFS took this approach because the 2001 – 2003 data are based largely on the use of J-hooks (as are the data for the first six months of 2004 before the circle hook requirement went into effect (July 6, 2004, 69 FR 40734)) whereas the second six months of 2004 are based on circle hook data. The results of the analyses on the subset of this dataset (*i.e.*, the first half of 2004) are included in Appendix A. In general, the inclusion of the January through June 2004 data with the 2001 – 2003 HMS logbook data did not change the predicted percent change in bycatch and discards for the different closures. Therefore, the inclusion of the additional six months of data from 2004 did not substantially alter any of the data presented in the Draft HMS FMP, or result in any changes to the overall conclusions or preferred alternatives in the Draft HMS FMP. Because these analyses were based on data (*i.e.*, 2004 HMS logbook data) that became available during the public comment period, these additional analyses were not available for public comment and are not included in this section (but are included in Appendix A). Given the additional six months of 2004 did not change the results of the time/area analyses done in the Draft HMS FMP, NMFS used 2001 – 2003 HMS logbook and POP data for the analyses throughout the rest of this section, except where other years are explicitly discussed.

NMFS used a Geographic Information System (GIS) program to plot observed (POP) and reported (HMS logbook) effort and catches of all non-target HMS (white marlin, blue marlin, sailfish, spearfish, and BFT), protected species (leatherback, loggerhead, and other sea turtles comprised of green, hawksbill, and Kemp's ridley sea turtles), and retained HMS species (swordfish, BFT, yellowfin, bigeye, and all BAYS tunas combined). Data for each of the species were mapped and compared spatially to one another in order to select the areas of highest concentration of bycatch. The areas of highest concentrations of bycatch for all species were then selected for further analysis. For these analyses, estimates of discards of all target and non-target HMS are comprised of both live and dead discards. All of the areas presented in this section and Appendix A were initially selected by examining the HMS logbook and POP data from 2001 - 2003 and identifying areas and times where bycatch was concentrated. NMFS has provided maps of bycatch for individual species (Figure 4.6 through Figure 4.13). In response to a specific request, NMFS has provided a map showing the spatial overlap of BFT, white marlin, and sea turtle bycatch in appendix A (Figure A-9 in Appendix A). For the spatial overlap analysis, NMFS combined the bycatch data from the HMS logbook for BFT, white marlin, and sea turtles into one combined dataset, and then joined them to a 10 x 10 minute grid (which is equivalent to approximately 100 $nm^2$) to get the number of discards for all species combined per 100 $nm^2$. A color scale is included to show the number of observations per 100 $nm^2$. The map shows the areas of highest bycatch for the three species combined. Monthly interactions for the different species (*i.e.*, temporal variability) were considered in the redistribution of effort analyses and can be seen in Table 4.13 and Table 4.16.

NMFS also took into account a closure area and time period received in a petition for rulemaking and considered an additional closure to reduce BFT discards in a reported spawning area in the Gulf of Mexico (Blue Ocean Institute *et al*., 2005; Block *et al*., 2005) (see alternative B2(c) discussion below). In addition, NMFS took into account a settlement agreement relating to white marlin, which was approved by the court in Center for Biological Diversity v. NMFS, Civ. Action No. 04-0063 (D.D.C.). With regard to the settlement agreement, NMFS specifically took into account five suggested white marlin time/area closures in the U.S. EEZ described on page 10 in a February 14, 2002, letter from the Biodiversity Legal Foundation, re: Atlantic White Marlin Critical Habitat Designation (see alternatives B2(g) – (k) in Section 2.1.2). The data used to analyze these potential closure areas include more recent data than was presented in the February 14, 2002, letter that relied on data from 1994 – 1996. All other time/area closure boundaries were selected based on the areas of highest interactions for a number of species (primarily white marlin, BFT, and leatherback and loggerhead sea turtles) (Figure 4.6 through Figure 4.12).

Following the selection of specific areas, NMFS performed spatial analyses to determine the fishing effort (number of hooks) and number of each species observed and reported caught inside each time/area closure in comparison to the rest of the Atlantic, Gulf of Mexico, and Caribbean, excluding the Northeast Distant restricted fishing area (NED). The NED data were not included in the analyses because the area was closed to commercial PLL fishing, except for a research experiment, during the period 2001 through 2003 (the years used in the analyses).

NMFS analyzed both absolute numbers of discards as well as areas of highest catch and catch per unit effort (CPUE: number of animals per 1,000 hooks) for non-target HMS and protected resources (white marlin, BFT, and sea turtles). In some cases these areas overlapped, in others, they did not (Figure 4.6, Figure 4.8, Figure 4.10, and Figure 4.11). This may be due to the fact that there are localized areas of high CPUE that may not necessarily represent the areas of highest bycatch in terms of absolute numbers. In order to avoid underestimation of bycatch reduction, in cases where the highest CPUE did not overlap with the areas of highest absolute numbers of discards, NMFS decided to further analyze the area that had the highest overall discards (in absolute terms), rather than areas with the highest CPUE. Thus, NMFS based the analyses on absolute numbers to maximize the reduction in overall number of discards. Under this approach, the projected number of discards may actually increase when redistribution of fishing effort is taken into account because high levels of effort are displaced into open areas with high CPUEs. Unlike other research on time/area closures (*e.g.*, Block *et al*., 2005), NMFS did not analyze CPUE in terms of soak hours (*i.e.*, the number of animals caught per hour of a longline set; soak time could be calculated by subtracting the time recorded when hooks were set in the water from the time recorded when hooks were pulled out of the water). Because of the variability between fishermen in reporting the soak time per set, NMFS felt the uncertainty associated with this measure was too high to accurately calculate effort in terms of soak hours (*i.e.*, was the start time recorded when the first hook went in the water or when the entire set was placed in the water? Or, similarly, was the end time recorded when the first hook was brought back onboard or when the entire set was retrieved?). Rather, NMFS used absolute numbers of catch as the most appropriate measure to assess time/area closures for bycatch reduction.

For all of the alternatives, NMFS compared monthly observed and reported catch and CPUE in each of the potential time/area closures to catch and CPUE fleet-wide, excluding the NED. Changes in bycatch and incidental catch resulting from time/area closures are thus expressed as a percentage of total U.S. Atlantic PLL catch, calculated on a monthly basis. NMFS evaluated the impacts of the closures both with and without redistribution of effort. The full redistribution of effort model assumed that fishing effort in a closure would be redistributed to all the remaining open areas. Therefore, evaluating impacts of a closure with and without redistribution of effort provides NMFS the potential range for which changes in catch could occur as a result of the closure(s). One end of the range assumes that all fishing effort within a given closed area will be eliminated (*e.g.*, fishermen will completely stop fishing in the closed area not displace that effort into other areas for the duration of the closure). Thus, the number and percent reduction in catch of both non-target and targeted species in these analyses represents the highest possible expected reduction. This would also represent the greatest negative social and economic impact that is anticipated for the industry. The other end of the spectrum assumes that all fishing effort in a closed area is distributed to open areas (*e.g.*, fishermen will move out of the closed area but continue fishing in surrounding open areas, move their business, or sell their permits to someone near an open area). The method used to calculate the resulting catch of target and non-target species is to multiply the effort that is being redistributed due to the closure by the CPUE for each species in all remaining open areas (for a complete description of the methodology used for redistribution of effort, please see Appendix A.) This end of the continuum would be expected to provide the least amount of bycatch reduction for a given closure depending on the CPUE of each species in all remaining open areas, which often provides mixed results regarding impacts on catch and bycatch and the economic and social impacts. In reality, the actual result may lie between the results obtained from these two different scenarios. In addition, if fishermen switch to different fisheries, this in turn, may have unanticipated consequences from gear interactions with other gear types and increased exploitation of other species not caught by PLL. Predicting fishermen's behavior is difficult, especially as some factors that may determine whether to stay in the fishery, relocate, or leave the fishery are beyond NMFS' control (fuel prices, infrastructure, hurricanes, etc.). While some fishermen will continue to fish in open areas of the Atlantic and Gulf of Mexico, others may be forced to leave the fishery entirely as a result of the closure.

During the comment period on the Draft HMS FMP, a number of commenters expressed concern over the effort redistribution model. These commenters felt that PLL vessels were not mobile enough to redistribute effort uniformly and that vessels in a certain area would move to adjacent areas (*e.g.*, vessels homeported in the Gulf of Mexico would stay in the Gulf of Mexico and would not move into the mid-Atlantic bight). Thus, the commenters felt that NMFS' "random" redistribution model did not accurately reflect the reality of the fleet.

As described in the Draft HMS FMP, the fleet-wide redistribution of effort model approach was used because an analysis of the mobility of the PLL fleet, completed in 2001 as part of a remand document regarding the implementation of a vessel monitoring system (NMFS, 2001), indicated that PLL vessels generally exhibit a high degree of mobility and are as likely to fish in areas away from their homeport as they are to fish in areas immediately adjacent to their homeport. This approach is also consistent with the methods used to analyze other time/area closures for the PLL fishery (NMFS, 2000; NMFS, 2004). The 1999 closure in the Northeastern United States to reduce BFT discards considered an effort displacement model for areas immediately adjacent to the closures because it was small in geographic size and short in duration compared to other time/area closures, and it was presumed fishermen would remain in this general area to retain incidentally-caught BFT while targeting other species. In the Draft HMS FMP, a similar approach of limiting the redistribution of effort to adjacent areas (Gulf of Mexico only) was used for alternative B2(a). NMFS analyzed redistribution of effort in the Gulf of Mexico only for alternative B2(a) because it is the smallest of the three closures considered in the Gulf of Mexico and represents the most likely case in which fishermen would stay in the

Gulf of Mexico. Since there would still be open areas left to fish in the Gulf of Mexico during this period (May through November), fishermen may turn to those areas rather than move out of the Gulf of Mexico and into the Atlantic.

Due to the difficulty with predicting fishermen's behavior once a closure is implemented, NMFS cannot predict with precision where fishing effort will be displaced. As described above, the effort redistribution model multiplied the effort seen in a potential closed area by the CPUE for each species in all remaining open areas. Thus, under this scenario, fishing effort is as likely to be displaced into areas with high bycatch rates as into areas with low bycatch rates, which could potentially result in an increase in bycatch of certain species. For example, interactions with leatherback sea turtles tend to be higher in the Gulf of Mexico, whereas interactions with loggerhead sea turtles tend to be higher along the Atlantic coast. If fishing effort is redistributed from the Gulf of Mexico into the Atlantic, there may be an increase in loggerhead sea turtle interactions. Conversely, if fishing effort is redistributed from the Atlantic to the Gulf of Mexico, leatherback turtle interactions may increase. Similar positive and negative results occur with the redistribution of effort model for other species. This indicates that, as fishing effort is squeezed into smaller open areas, bycatch of one species may decrease, while bycatch of another species may increase.

While the current redistribution of effort model could be improved in the future, the model used by NMFS in this rulemaking has been successfully used by NMFS in past rulemakings and is the based on the best science currently available for the Atlantic HMS PLL fishery. The current redistribution of effort model accounts for displaced effort due to a closure, and provides quantitative estimates of changes in bycatch, discards, and retained catch as a result of a closure. Other models have been used for time/area analyses; however, in many cases, these models did not consider redistribution of fishing effort (*e.g.*, SCRS/2005/011; Block *et al.*, 2005). Those models that have investigated redistribution of effort as a result of time/area closures have been random utility models (RUMs) that have been used for the Hawaiian PLL fishery (*e.g.*, Curtis and McConnell, 2004), and a closed area model used by the New England Fishery Management Council (NEFMC) to evaluate closures for the groundfish fishery (NEFMC, 2003). Both types of models are econometric models, which predict where fishermen will reallocate effort based on maximizing revenues and/or profits. However, neither model is currently designed to be used for the HMS PLL fishery, and in order for either framework to be applicable to a time/area analysis for the Atlantic HMS PLL fishery, NMFS would have to develop a specific model for the PLL fleet based the current economics, fishing grounds, and fishing effort of the Atlantic HMS PLL fleet. Such development will take additional time and effort. An additional RUM was developed for HMS (Strand, 2004) based on 1996 data. While NMFS considered using this model, it was not used for the current analyses because it was based on very large areas that were not applicable to the current time/area closures being considered, and because the data were outdated (*i.e.*, 1996 versus 2001 – 2003). In addition, the Strand (2004) model was based on J-hook bycatch and economic data. Given the current PLL fishery regulations require circle hooks, and that the applicability of J-hook data is questionable, NMFS may want to develop a random utility model once it has circle hook bycatch and economic data. Once NMFS has complete and finalized circle hook data, NMFS may consider revising the model in the future to make it applicable to the current closed areas. In the meantime, NMFS has chosen to use the current redistribution of effort model that has been used in past rulemakings.

As noted in earlier chapters, the Office of Management and Budget (OMB) issued a directive requiring Federal Agencies to have “influential scientific information” and “highly influential scientific assessments” peer reviewed. Since NMFS decided that sections of the HMS FMP, including the time/area section, could be classified as “influential scientific information,” NMFS had three independent (*i.e.*, people not involved in the drafting of the document) scientists review these sections pursuant of the OMB directive. Two of the peer reviewers were NOAA scientists and one peer reviewer was an independent scientist outside of NOAA. One of the peer reviewers (Appendix E) stated that, “The model is based on generally accepted principles in fisheries science. In general, such models rely on a set of assumptions related to static patterns of relative abundance at some temporal and spatial resolution, limited consideration of fish movements, and incomplete understanding of the effects of closure areas on redistribution of effort. Nonetheless, such models can provide useful insights for comparison of alternative management strategies. Without such a model there would be no such pragmatic way of comparing the potential closed areas. In general, it is probably safe to assume that the limitations of the model will be comparable across alternatives. Thus, the rankings of each alternative should be relatively insensitive to the assumptions.” Another OMB reviewer suggested testing “other plausible assumptions” or “redistribution scenarios.” The third OMB reviewer stated that, “Given the assumption of effort redistribution, it is difficult to believe that NMFS will be able to implement a time/area closure that does not have ecological impacts that counter gains. Hence, for time/area closures to be effective, assumptions on effort redistribution need to be rigorously tested…[and] reality likely lies between no effort redistribution and complete redistribution.”

In response to the public comments received and to some of the comments by the OMB peer reviewers, NMFS investigated the movement of the PLL fleet from 2001 through June of 2004 to see where vessels fished in relation to their reported homeports. This mobility analysis broke the Atlantic, Caribbean and Gulf of Mexico into six distinct areas, with one area, Area 2, split along the west and east coasts of Florida (Areas 2A and 2B, respectively; Figure A.5). Using GIS, NMFS plotted vessels according to where they fished (*i.e.*, made sets) in those six different areas in relation to their reported homeport. This provided NMFS with a spatial understanding of the distance different vessels could move. Figure A.6 shows the results of this analysis. Overall, most of the movement and effort (in terms of hooks) out of the Gulf of Mexico (Areas 1 and 2A) went to Area 6, the high seas, but some other effort was also moved up along the eastern seaboard (Figure A.7). Conversely, a few vessels that fished along the eastern seaboard also moved into the Gulf of Mexico, although the movement was somewhat limited.

NMFS also investigated the physical characteristics of vessels to see if there were any differences in the vessels that reported fishing only in the Gulf of Mexico compared to vessels that reporting fishing out of the Gulf of Mexico. NMFS found no significant differences in the vessels’ length ($t_{104} = 0.43$, $P = 0.35$) or vessels’ horsepower ($t_{104} = 0.43$, $P = 0.66$) for vessels that fished only in the Gulf of Mexico versus those that fished out of the Gulf of Mexico (Table A.36). These results indicate that vessels that fish exclusively in the Gulf of Mexico have the physical capability (in terms of vessel size and horsepower) to fish outside of the Gulf of Mexico. Furthermore, despite the upgrading restrictions, this indicates that the vessel owners could sell their permits and/or boats to fishermen who may like to fish outside the Gulf of Mexico.

NMFS also provided maps showing where the PLL sets have occurred inside and outside the U. S. EEZ (Figure A.8a). These maps show the true extent of fishing effort by the U.S. PLL fleet whereas most of the other figures in Chapter 4 and Appendix A are focused on the U.S. EEZ. Figure A.8b shows the size of closures B2(a) and B2(c) in the Gulf of Mexico relative to the entire Gulf of Mexico and shows that the U.S. PLL fleet has been fishing within and outside the U. S. EEZ. Figure A.8c shows that PLL vessels can relocate to distant ports and fish outside of their immediate homeport region (in some cases, up to 4,000 miles) whereas movement from the Gulf of Mexico to the Mid-Atlantic Bight is only 1,500 miles (Figure A.8d).

Based on these analyses, NMFS evaluated several different scenarios of the redistribution of fishing effort model for some of the closed areas where each scenario had different assumptions regarding how fishing effort would be redistributed into open areas. NMFS evaluated different scenarios for redistribution of fishing effort for B2(a) since it was the smallest closure in the Gulf of Mexico. NMFS also evaluated different scenarios of redistribution of effort for the B2(c) based on substantive issues identified during from public comments on this alternative. Finally, NMFS also evaluated different scenarios for the redistribution of effort model for B2(b) because it was the smallest closure along the eastern seaboard. Specifically, NMFS calculated redistribution of effort only to open areas along the eastern seaboard for a closure in the Northeast [B2(b)]. NMFS also redistributed fishing effort in the open areas of the Gulf of Mexico and Area 6 for two closures in the Gulf of Mexico (B2(a) and B2(c); see Appendix A). By doing this, NMFS was able to investigate how different assumptions of redistribution of fishing effort for different size closures in different regions of the Gulf of Mexico and Atlantic would effect predictions of bycatch, discards, and retained catch.

Taken with the results from both no redistribution of effort and the full redistribution of effort model, these additional scenarios provide estimates of changes in bycatch and retained catch somewhere in-between the two base scenarios (*i.e.*, some movement is expected, and thus, some redistribution of effort is expected into a particular area (in this case, Area 6)). However, these additional scenarios assume that the same amount of effort is moved out of the Gulf of Mexico regardless of the size of the closure in the Gulf of Mexico, when in reality, larger closures may result in more movement out of the Gulf of Mexico since a smaller area in the Gulf of Mexico will be open for fishing. These scenarios also assume that fishermen do not relocate, possibly due to community ties to unloading docks, processing plants, etc. However, it should be noted that while fishermen may prefer not to disrupt ties to their communities, the available data indicate that fishermen from the Gulf of Mexico already fish outside of the Gulf of Mexico. If a large closure were implemented in the Gulf of Mexico, it is likely that additional fishermen would move their fishing locations or sell their permits rather than go out of business. However, in the future, NMFS intends to investigate the choices fishermen have made regarding previous closures (*i.e.*, did they move, sell their permits, go out of business, retain their permit but fish for something else, etc?). This type of analysis could help NMFS improve the redistribution of effort models used in the future.

Data for each of the new closures (alternatives B2(a) through (e)) were analyzed with and without redistribution of effort. Both POP and HMS logbook data were used to analyze bycatch and discards without redistribution of effort. However, only the HMS logbook data were used to estimate bycatch with redistribution of effort because these data are collected for the entire fleet and provide an effort estimate for the entire fleet needed for redistribution calculations, whereas the POP data are only collected from a portion of the fleet. NMFS is aware that discards may be underreported in the HMS logbook data compared to the POP data. However, if there are no differences in underreporting for different species between different regions, then the relative effect of each closure on bycatch reduction for each species should be comparable across alternatives. Cramer (2000) compared dead discards from the HMS logbook and POP data. In her paper, Cramer used POP data to estimate dead discards of undersized swordfish, sailfish, white and blue marlin, and pelagic sharks from the PLL fishery operating in the U.S. Atlantic, Caribbean and Gulf of Mexico. Cramer (2000) provided the ratio of catch estimated from the POP data divided by the reported catch in the HMS logbooks. This ratio indicated the amount of underreporting for different species in a given area. Due to public comment that expressed concern over using HMS logbook data rather than POP, NMFS analyzed the ratios in Cramer (2000) to test whether underreporting varied for different species in different parts of the Atlantic, Caribbean and Gulf of Mexico. NMFS used a Kruskal-Wallis test (a non-parametric test equivalent to a parametric Analysis of Variance) to account for small sample sizes and non-normally distributed data. NMFS found that there was no difference in the ratio of estimated catch versus reported catch for undersized swordfish, sailfish, blue marlin, white marlin, or pelagic sharks (undersized swordfish: Chi-square = 3.63; *d.f.* = 5; $P$ = 0.60; sailfish: Chi-square = 1.72; *d.f.* = 5; $P$ = 0.89; blue marlin: Chi-square = 3.89; *d.f.* = 5; $P$ = 0.57; white marlin: Chi-square = 2.97; *d.f.* = 5; $P$ = 0.70; pelagic sharks: Chi-square = 4.78; *d.f.* = 5; $P$ = 0.44). Therefore, there were no differences in underreporting between the POP and HMS logbooks for the above species in the Atlantic, Caribbean, or Gulf of Mexico. Based on the available information, NMFS believes HMS logbooks may underestimate the amount of bycatch, however, the relative effect of each closure for each species should be comparable across alternatives. While the data used in the Cramer (2000) study represented an earlier time period (1997 – 1998) compared to the 2001 – 2003 data used here, it gives some indication that the use of HMS logbook data over POP data should not invalidate or bias the results of the time/area analyses. NMFS will continue to investigate potential differences in reporting between HMS logbook and POP data for all discarded species as well as potential biases in reporting between geographical areas for different species.

Results of the Analyses

The No Action alternative, B1, would maintain the existing time/area closures (Figure 4.1) and would not implement any new time/area closures. These areas include the June Northeastern U.S. closure (effective June 1, 1999), the DeSoto Canyon (effective November 1, 2000), the Charleston Bump and Florida East Coast closures (effective March 1, 2001), and the Northeast Distant closed area (effective July 9, 2002, and modified July 6, 2004). The Northeast Distant area is currently a restricted fishing area with specific gear requirements (69 FR 40734, July 6, 2004). Since most of the time/area closures were implemented in 2001 or earlier, data from 2001 – 2003 provide the basis for evaluating the effectiveness of the closures. The following sections provides an overview of the effectiveness of the existing time/area closures at reducing discards and bycatch and in maintaining target catches for the entire fishery. These analyses are ongoing and additional data are collected and reviewed annually.

Data used in these analyses were taken from the HMS logbook database administered through the NMFS Southeast Region. The reported catch and discards for each species and the number of hooks set were pooled by month (Table 4.6 and Table 4.7). The monthly and annual Atlantic wide totals catch and discards were calculated for each species. A reference period of 1997 – 1999 was chosen for the initial comparisons to examine the effect of closures implemented in 2000 – 2001. The percent change from 1997 – 1999 to 2001 – 2003 in numbers kept and discarded were calculated for the domestic PLL fleet for the entire Atlantic basin (Table 4.6 and Table 4.7). Changes in the numbers of fish caught and discarded were compared to the predicted changes presented in Regulatory Amendment 1 to the 1999 FMP (NMFS, 2000). The reported distribution of hooks set by area each year was examined to evaluate trends and/or shifts in fishing effort (Table 4.8). In addition, the reported number of fish kept and discarded in the MAB and NEC was compared to the reported numbers for all other areas combined in order to evaluate the effectiveness of the June Northeastern U.S. closure (Table 4.9).

The analyses showed that the existing closures have been effective at reducing bycatch of protected species and non-target HMS and have provided positive ecological benefits. For example, the overall number of reported discards of swordfish, BFT and bigeye tunas, pelagic sharks, blue and white marlin, sailfish, and spearfish have all declined by more than 30 percent. The reported discards of blue and white marlin declined by about 50 percent and sailfish discards declined by almost 75 percent. The reported number of sea turtles caught and released declined by almost 28 percent (Table 4.6 and Table 4.7). Thus, the No Action alternative would continue to have a positive ecological impact by maintaining a low overall byctach of non-target and protected species.

The closures have had an impact on landings of target species as well. For example, from 1997 to 2003, the number of swordfish kept declined by nearly 28 percent, the number of yellowfin tuna kept declined by 23.5 percent, and the total number of BAYS kept (including yellowfin tuna) declined by 25.1 percent (Table 4.6). The reported declines (without redistribution of effort) in swordfish kept and discarded, large coastal sharks kept and discarded, and dolphins kept were similar to the predicted values developed for Regulatory Amendment 1. Reported discards of BFT, pelagic sharks, all billfish (with the exception of spearfish for which no predicted change was developed in Regulatory Amendment 1) and total BAYS kept have all declined more than the predicted values. Thus, the existing closures appear to have had a positive ecological impact on these species as well. However, such declines in landings may also have had negative economic impacts on commercial fisheries as discussed later in this section.

Overall effort in the Atlantic PLL fishery based on reported number of hooks set declined by 15 percent during the pre- to post-closure period (Table 4.8). The distribution of effort does not indicate a major shift in fishing effort as a result of the time/area closures (Table 4.8). The average number of hooks reported set in 2001 – 2003 by area was compared to the average for 1997 – 1999. Declines in effort were reported for the majority of the areas. However, fishing effort increased during the pre- to post-closure period in the Gulf of Mexico, by slightly more than eight percent (Table 4.8). This increase could be the result of a shift in effort attributable to the implementation of East Florida Coast closure area. Reported effort also increased in the Sargasso (SAR) and North Central Atlantic (NCA) statistical areas where little activity had been reported prior to 2002. This increase could also represent a shift in effort due to implementation of the East Florida Coast closed area, and possibly the seasonal Charleston Bump closure. Effort in the South Atlantic Bight, where the Charleston Bump closure is located, declined by 30 percent from the 1997 – 1999 level. Effort in the MAB and NEC also declined, 26 and 31 percent, respectively. The June Northeastern U.S. closed area is located within these two areas.

The June Northeastern U.S. closed area (64 FR 29090, May 28, 1999) was implemented in order to decrease BFT discards in the Atlantic PLL fishery. The closure spans a portion of two statistical reporting areas, the MAB and the NEC. The reported effort, catch, and discards were combined for these two areas to evaluate the effectiveness of the closure (Table 4.9). The reported effort, catch, and discards for the remaining areas were also combined and presented.

It appears that BFT discards in the MAB and NEC have been considerably reduced since the implementation of the June closure in 1999 (Table 4.9). Reported discards of BFT prior to implementation of the closure ranged from 558 to over 2,700 per year. Since 1999, the number of BFT reported discarded has remained below 500 per year. The number of swordfish kept in the MAB and NEC has increased since the closure was implemented while the number of billfish discarded has declined.

Analysis of the change in effort and bycatch after implementation of existing closures indicates that reduction in bycatch may have been greater than predicted with redistribution of effort, and in some cases, without redistribution of effort. There are several possible explanations for the higher than predicted decline in bycatch and effort resulting from time/area closures that may have ecological impacts as well as economic repercussions on fishing behavior and the PLL fishing industry: (1) stocks may be declining; (2) time/area closures may have acted synergistically with declining stocks to produce greater declines in catch than predicted; (3) fishermen may have left the fishery; and (4) fishing effort may have been displaced into areas with lower CPUEs. With regard to the last point, the redistribution of effort model is incapable of making predictions based on a declining CPUE. Instead the model assumes a current CPUE that remains constant in the remaining open areas when estimating reductions. It is possible that one or more of these factors, or others, may have contributed to the observed decline in landings and bycatch in recent years. However, despite these declines, several species continue to be overfished with overfishing still occurring, warranting further consideration of closures or the other alternatives described in this Final HMS FMP.

In addition to B1, the No Action alternative, NMFS analyzed several new potential time/area closures. After comparing the potential bycatch reduction for all of the closures that NMFS initially considered (see Chapter 2), NMFS chose five closures with the highest overall bycatch for further analysis in addition to complementary measures in the Madison-Swanson and Steamboat Lumps Marine Reserves and BLL closures to protect smalltooth sawfish. Alternatives B2(a) and B2(b) were chosen for analysis because they had higher overall discards of white marlin, BFT, and most other species than any of the other closures. Alternative B2(c) was chosen for analysis in response to a petition received by NMFS from several conservation organizations requesting consideration of a closure of the "Gulf of Mexico bluefin spawning area" (Figure 4.2) (Blue Ocean Institute *et al*., 2005). The area analyzed was obtained directly from the petition. Alternatives B2(d) and B2(e) were chosen for analysis in order to determine if any other closure, or combination of closures, would be more effective at reducing bycatch than the alternatives B2(a), B2(b), or B2(c). The analyses indicated that almost all of the closures and combinations of closures considered for white marlin, BFT, or sea turtles would result in a net increase in bycatch for at least some of the primary species considered when redistribution of fishing effort was taken into account (Table 4.5). In addition, the predicted reduction in bycatch when redistribution of fishing effort was taken into account was typically less than 30 percent for any given species, with overall reduction in the number of individual species being very low (Table 4.5 and Table A.1 in Appendix A).

Currently, in terms of new closures, NMFS has chosen to go forward with only the complementary measures in the Madison-Swanson and Steamboat Lumps Marine Reserves. This is due, in part, to all the available data used in the time/area analyses being based on J-hook data. A circle hook requirement for the PLL fishery went into effect on June 30, 2004, in the NED (69 FR 40734), and in all remaining areas on August 6, 2004. NMFS currently only has finalized data on the catch associated with circle hooks from July through December of 2004 (see Appendix A). Based on the NED experiment, it is expected that circle hooks likely have significantly different catch rates than J-hooks. However, since the impact of circle hooks on bycatch is uncertain for most species (except sea turtles and swordfish), further investigation is required to determine the impact of any new time/area closures. NMFS anticipates that 2005 HMS logbook data will become available in the summer of 2006, and NMFS will continue to monitor and analyze the effect of circle hooks and bycatch reduction. NMFS is also awaiting additional information regarding the status of the PLL fleet after the devastating hurricanes that occurred in the Gulf of Mexico during the fall of 2005. The number of active vessels and level of fishing effort will be assessed beginning in the summer of 2006, when the 2005 HMS logbook final data becomes available.

Alternative B2(a) would prohibit the use of PLL gear by all U.S. flagged-vessels permitted to fish for HMS in an 11,991 $nm^2$ area of the central Gulf of Mexico (Figure 4.2) from May through November of each year (7 months). The effectiveness of alternative B2(a), and all subsequent closure alternatives, was evaluated by determining the percent reduction in bycatch of non-target HMS, protected species, and retained species on a monthly basis with and without redistribution of effort. Without redistribution of effort, the observer program data indicate that the alternative B2(a) from May through November would potentially reduce discards (live and dead combined) of all non-target HMS and sea turtles from 4.0 percent for loggerhead sea turtles to 19.6 percent for sailfish (Table 4.4). Without redistribution of effort, the logbook data indicate that alternative B2(a) from May through November would potentially reduce discards from 3.4 percent for loggerhead sea turtles to 17.6 percent blue marlin discards (Table 4.5). Thus, the percent reductions in most bycatch species were very similar for both the observed and reported data.

Data from monthly catches and discards were examined for both a year-round closure and a seven-month closure (Table 4.4 and Table 4.5). The annual seven-month closure was selected for further analysis because the reductions in bycatch were similar to the year-round closure without redistribution of effort, except for BFT. In some cases, reductions in bycatch were higher than the year-round closure with redistribution of effort (Table 4.5). For example, white marlin discards (live and dead combined) increased 0.9 percent with redistribution of effort for the year-round closure, as did sailfish (1.1 percent), spearfish (4 percent), and BFT discards (7.9 percent). The May through November closure, on the other hand, would reduce discards of all species except loggerhead sea turtles and BFT.

With redistribution of effort, the logbook data indicate that there would be a reduction in bycatch for some species, but an increase in others. For example, the bycatch of leatherback sea turtles would be decreased by eight percent (76 leatherback sea turtles over a three year period, or 25 per year; yearly averages can be calculated by dividing the numbers in the tables by three), whereas loggerhead sea turtle interactions would potentially increase by 7.9 percent (six loggerhead sea turtles over a three year period, or two per year) (Table 4.5), pelagic and LCS discards would increase by 14.5 percent and 11.7 percent, respectively (Table 4.10a), and BFT discards would increase by 10.3 percent (75 discards over a three year period, or 25 per year; Table 4.11a). For some of the species, the percent reduction in discards was minimal. For example, white marlin discards are predicted to decrease by only 2.7 percent. This amounts to a projected decrease of 85 white marlin over three years, or 28 white marlin per year (3,143 x 0.027 = 85) (Table 4.5 and Table 4.10a). When compared to the overall annual reported white marlin discards (1,047 annually; Table 4.10a), this reduction would provide minimal benefit. Thus, while there may be an ecological benefit for some species, such as leatherback sea turtles and blue marlin, the benefits to other species as a result of this closure are less clear.

As explained above, NMFS considered redistribution of effort in the Gulf of Mexico only for alternative B2(a) because it was the smallest closure in the Gulf of Mexico and the most likely scenario where fishermen would stay in the Gulf of Mexico while this closure was in place (*i.e.*, there would still be enough fishing areas open in the Gulf of Mexico to fish in unlike the larger closures). The result was a predicted increase in bycatch for some species and reductions in bycatch for others (Table 4.10b). Interactions with spearfish and discards of LCS, for example, could increase by 3.3 percent and 3.6 percent, respectively (Table 4.10b), whereas BFT discards could decrease by 1.2 percent (Table 4.11b). Interestingly, the catch of all targeted species, with the exception of BFT, are predicted to increase as a result of the closure (Table 4.11b). With redistribution of effort in the Gulf of Mexico and Area 6 combined, the logbook data from 2001 – 2004 indicated that there could be reductions in bycatch for some species, but increases in others. For example, bycatch could range from a 15.4 percent decrease for other sea turtles to an increase of 4.7 percent for sailfish (Table A.37). Bluefin tuna discards could increase by 1.6 percent with redistribution of effort (Table A.38). These results indicate that for alternative B2(a), even when effort was assumed to be redistributed in the Gulf of Mexico only, or in the Gulf and Area 6, there was still a potential for increased discards of certain species.

Alternative B2(b) would prohibit the use of PLL gear by all U.S. flagged-vessels permitted to fish for HMS in a 2,251 $nm^2$ area of the Northeast in June primarily to reduce BFT discards (Figure 4.2). NMFS decided to further analyze this area because it had a high concentration of BFT discards, with a greater number of discards than any other area in the Atlantic or the Gulf of Mexico. For example, from 2001 – 2003, there were 461 reported BFT discards in this comparatively small area, compared to 470 reported discards in the entire Gulf of Mexico (~300,000 $nm^2$) (Figure 4.13). Furthermore, approximately 80 percent of the discards in alternative B2(b) (365 BFT discards) occurred in the month of June only (Table 4.12). In contrast, the majority of BFT discards in the Gulf of Mexico occurred over a three-month period from March through May and were much more randomly and broadly distributed (Table 4.13).

Additionally, alternative B2(b) had a lower number of BFT kept (34 over three years; Table 4.12) than the B2(a) closure in the Gulf of Mexico (133 over three years; Table 4.11b), which may have potential social and economic consequences for both areas, as discussed in greater detail later in this section. NMFS considered both a year-round and a June only closure, but decided not to analyze a year-round closure because the percent reductions were similar to the June only closure for most of the species considered (Table 4.5). The following information thus pertains to the June only closure.

According to observer program data, alternative B2(b) would reduce BFT discards by 15.4 percent and loggerhead sea turtles by 6.0 percent. All other non-target HMS and protected resources would experience zero-percent reductions (Table 4.4). Without redistribution of effort, the logbook data indicate that alternative B2(b) would result in a 22.6 percent decrease in BFT discards (461 BFT over 3 years, or an average of 154 per year) (Table 4.12) and an 11.2 percent decrease in loggerhead sea turtle interactions (Table 4.14). Therefore, the percent reductions predicted from HMS logbook and POP data were similar. While not large, most other species would have reductions in bycatch as predicted from the logbook data as well, ranging from a zero-percent reduction in sailfish and spearfish discards to 14.9 percent for pelagic sharks (Table 4.14). With redistribution of effort, the area would result in a 21.9 percent reduction in BFT discards (354 BFT over three years or 118 per year) (Table 4.15 and Table A.5 in Appendix A), but relatively small increases in bycatch for nearly all of the other species except leatherback (-1.3 percent; Table 4.14) and loggerhead sea turtles (-10.3 percent; Table 4.14).

Although there may be an ecological benefit for BFT and loggerhead sea turtles as a result of this closure, the benefits to other species are less clear and may, in fact, be negative. Clearly, alternative B2(b) would reduce BFT discards, but would potentially increase the bycatch of other species. This is likely the result of a lower than average CPUE for most of the other species in the area. When redistribution of effort is considered, there may be an increase in bycatch of species such as blue and white marlin, spearfish, sailfish, and LCS.

As explained above, NMFS considered redistribution of effort in the Atlantic only for alternative B2(b) given its small size and temporal duration (as opposed to redistribution of effort in all areas of the Atlantic and Gulf of Mexico). The result was a predicted slight increase in bycatch for some species and slight reductions in bycatch for others. Interactions with leatherback and loggerhead sea turtles could decrease by 0.8 percent and 5.9 percent, respectively, whereas blue and white marlin discards could increase by 0.9 and 2.0 percent, respectively (Table A.39). However, BFT discards could decrease by 15.1 percent resulting in 333 fewer discards over three years or 111 fewer per year (Table A.40).

Alternative B2(c) would prohibit the use of PLL gear by all U.S. flagged-vessels permitted to fish for HMS in a 101,670 $nm^2$ area in the Gulf of Mexico from April through June (three months) each year (Figure 4.2). According to observer program data, without redistribution of effort alternative B2(c) would reduce discards of all non-target HMS and protected resources from a minimum of 2.3 percent for spearfish to a maximum of 25.0 percent for other sea turtles (Table 4.4). Without redistribution of effort, the logbook data indicate that alternative B2(c) would potentially reduce discards of all of the species being considered from a minimum of 0.8 percent for pelagic sharks to a maximum 21.5 percent for BFT (Table 4.5 and Table 4.16). With redistribution of effort, however, bycatch is predicted to increase for all species except leatherback and other sea turtles (Table 4.16). Even BFT discards, which showed a fairly dramatic decline without redistribution of effort, are predicted to increase by 9.8 percent with redistribution of effort (for an overall increase of 158 BFT over three years or an average increase of 53 per year) (Table 4.13 and Table A.5 in Appendix A). The apparent increase in predicted BFT discards with redistribution of effort is likely due to the fact that BFT are caught in months other than April through June in the Gulf of Mexico, as well as the high number of BFT discards in other areas, as described in alternative B2(b) above. However, it must be noted that the increase of BFT discards in other areas outside of the Gulf of Mexico are most likely discards of non-spawning BFT such as non-spawning adults, juveniles, and sub-adults. Therefore, there is not necessarily a 1-to-1 equivalency between benefits to individual spawning BFT in the Gulf of Mexico and individual non-spawning BFT outside of the Gulf of Mexico. However, increasing the number of discards of BFT in areas outside the Gulf of Mexico could still be detrimental to the stock. Bluefin tuna kept (landed), on the other hand, would be reduced by 18.3 percent (a decrease of 110 BFT kept over three years, or an average of 37 per year), indicating that the Gulf of Mexico has a high number of BFT landed in addition to BFT discards (Table 4.13 and Table A.5 in Appendix A). As with the alternatives described above, with redistribution of effort, there may be an ecological benefit to some species, but negative impacts on others. For example, LCS discards are predicted to increase 25.9 percent and loggerhead sea turtles by 23.5 percent under this alternative Table 4.16.

NMFS also performed a second scenario of the redistribution of effort analysis where effort was redistributed to open areas of the Gulf of Mexico and Area 6 of the Atlantic only (see Figure A.5 in Appendix A). The results of this analysis indicated a potential reduction in bycatch for white marlin, leatherback and other sea turtles, and pelagic shark discards, bluefin discards, yellowfin discards, and BAYS tuna discards, with the largest being for BFT (19.3 percent decrease over 3 ½ years or ~ 122 discards per year) (Tables A.41 and A.42, Appendix A). However, the analysis also predicted an increase in bycatch of blue marlin, sailfish, spearfish and large coastal sharks (Table A.41 in Appendix A). The largest expected increase would be for LCS of 12.8 percent or 2,454 LSC over 3 ½ years. Interestingly, the analysis suggested that this closure could result in an increase in the amount of swordfish kept. This is expected to be from more fishermen utilizing the area around the Desoto Canyon closure, since effort in the western portion of the Gulf of Mexico would be squeezed into the eastern portion of the Gulf of Mexico where swordfish catch rates are higher. However, it is unknown how realistic this result is; if increased effort in the eastern portions of the Gulf of Mexico could occur, more fishermen may leave the Gulf of Mexico to fish in Area 6 due to overcrowding in the Gulf of Mexico.

According to the full redistribution of effort model, the petition to close 101,670 $nm^2$ in the Gulf of Mexico from April through June each year (alternative B2(c)) was predicted to decrease the number of BFT kept by an average of 37 fish per year and is predicted to increase the number of BFT discards by an average of 53 fish per year (Table A.5 in Appendix A). Alternative B2(b), on the other hand, would close 2,251 $nm^2$ in the Northeast for the month of

June only, and would potentially reduce the number of BFT discards by 118 per year (Table A.5 in Appendix A). Although alternative B2(b) is not considered a BFT spawning area, data from the observer program indicate that large fish (>171 cm TL) are present in the area (2001 – 2003 POP data). Additionally, there is evidence to indicate that the area is utilized as a feeding and staging area by BFT prior to migrating to the Gulf of Mexico to spawn (Block *et al*., 2005). Pop-up satellite tags on BFT tagged in feeding areas of the Northeast show fairly rapid (~ one month) migrations from the Northeast to the Gulf of Mexico (Block *et al*., 2005). Hence, while NMFS recognizes that the same proportion of western spawning BFT would not be protected from a closure in the Northeast as one in the Gulf of Mexico, potentially a small proportion of western spawning-size BFT could be protected by a closure like B2(b), especially given the prevalence of larger individuals in Northeast area from the POP data. Therefore, a closure like B2(b) may be able to protect a few spawning-size individuals as well as pre-spawners, or sub-adults, which are also valuable age classes with regard to the stock (although, presumably, there is a mixture of eastern and western origin fish in this area, and a closure in this area may protect sub-adults of western as well as eastern origin). Furthermore, the total proportion of dead discards in the Northeast was similar to the Gulf of Mexico. In the Northeast, 48 percent (219 out of 461) of all BFT discards from 2001 – 2003 were discarded dead, whereas 53 percent (249 out of 470) of all BFT discards from the Gulf of Mexico were discarded dead (as reported in the 2001 – 2003 HMS Logbook). Given the high number of discards in the Northeast, a closure there may provide similar ecological benefits compared to a closure in the Gulf of Mexico (depending on post-release survival in the two areas). In addition, a small closure in the Northeast would minimize the economic impacts when compared to a closure of 101,670 nm$^2$ in the Gulf of Mexico, as discussed in more detail later in this section.

Alternative B2(d) would prohibit the use of PLL gear by all U.S. flagged-vessels permitted to fish for HMS in a 162,181 nm$^2$ area in the Gulf of Mexico west of 86 degrees W. Long. year-round (Figure 4.2), thus closing an area where approximately 50 percent of all domestic effort (Atlantic, Gulf of Mexico, and Caribbean) and 90 percent of all domestic effort in the Gulf of Mexico has been reported in recent years (2001 – 2003). According to observer program data, alternative B2(d) would have the greatest positive ecological impact of all the alternatives considered (Table 4.4). It would potentially reduce discards (live and dead combined) of all non-target HMS and protected resources by a minimum of 14 percent for loggerhead sea turtles to a maximum of 75 percent for other sea turtles (Table 4.4). Similarly, the logbook data without the redistribution of effort indicated that there could be large reductions in all non-target HMS, ranging from a 10.1 percent reduction in loggerheads to 83.5 percent reduction in spearfish discards (Table 4.5 and Table 4.17).

With redistribution of effort, alternative B2(d) is predicted to reduce discards of blue marlin, sailfish, spearfish, and leatherback sea turtles, but increase discards of white marlin, BFT, pelagic sharks, LCS, and loggerhead sea turtles (Table 4.5, Table 4.17, and Table 4.18). Loggerhead sea turtles, in particular, would be of great concern since interactions could potentially increase by 65.5 percent (117 over three years, or an average of 39 per year; Table A.1 in Appendix A). BFT discards could increase by 38 percent (614 over three years or 205 per year; Table A.5 in Appendix A), and pelagic shark discards could increase by 88 percent (30,194 over three years, or an average of 10,064 per year; Table 4.17). The reason for the dramatic increase in discards for some species with redistribution of effort is that these species are more commonly encountered in the Atlantic than the Gulf of Mexico. With nearly 50 percent of overall effort predicted to redistribute into open areas of the Atlantic, the discards of these species would likely increase. Given approximately 90 percent of the fishing effort in the Gulf of Mexico has in recent years occurred in this area, if this closure were implemented, very few areas would be left open for fishing in the Gulf of Mexico. As a result, in order to stay in business, fishermen would likely have to move out of the Gulf of Mexico. Fishermen might also sell their permits to fishermen outside of the Gulf, resulting in a further increase in fishing effort in open areas. For an example of the impact of redistribution of effort, see Table A.28 in Appendix A. Since a majority of leatherback sea turtles interactions occur in the Gulf of Mexico, and a majority of loggerhead interactions occur in the Atlantic, closing an area of this size in the Gulf of Mexico could potentially redistribute effort to areas of the Atlantic where loggerhead interactions are higher.

Alternative B2(e) would prohibit the use of PLL gear by all U.S. flagged-vessels permitted to fish for HMS in a 46,956 $nm^2$ area in the Northeast year-round (Figure 4.2). The area was primarily considered to reduce loggerhead sea turtle interactions, which occur with greater frequency there than in nearly all other areas. Without redistribution of effort, the closure is predicted to decrease bycatch and discards of all non-target HMS and protected species by a minimum of 0.3 percent for spearfish, to a maximum of 40.7 percent for BFT discards (Table 4.5, Table 4.19, and Table 4.20). However, with redistribution of effort, bycatch of all species except pelagic sharks, BFT, leatherback, and loggerhead sea turtles, is predicted to increase (Table 4.19).

Given the mixed results for some of the species in each of the alternatives analyzed individually above, NMFS considered combining alternatives B2(a) and B2(b), as well as alternatives B2(d) and B2(e) to maximize bycatch reduction. Combining these areas could potentially reduce the number of discards beyond what could be achieved by a single closure. For alternatives B2(a) and B2(b), NMFS considered both a year-round closure and a closure during the months of May through November for alternative B2(a), combined with a closure during June only for alternative B2(b), similar to the individual closures described previously. For alternatives B2(d) and B2(e), NMFS considered a year-round closure only. It should be noted that percent reduction in discards and retained catch without redistribution of effort for the combination of closures is simply the addition of percent reduction without redistribution of effort for the individual closures (Table 4.5 and Table 4.15). Therefore, only a discussion of predicted impacts of combinations of closures with redistribution of effort is included below.

With redistribution of effort, combining alternatives B2(a) and B2(b) year-round would increase discards of most species except BFT and sea turtles (Table 4.5 and Table 4.21). Thus, a year-round closure of both of these areas could have a positive ecological impact on BFT and all sea turtle species, but a negative impact on blue and white marlin, sailfish, spearfish, pelagic sharks, and LCS. Combining alternatives B2(a) and B2(b) on a seasonal basis from May through November for B2(a) and June only for B2(b), as described above, would result in reductions in discards of all species except sailfish (which would increase 1.5 percent, or 15 over three years), pelagic sharks (which would increase 9.6 percent or 3,276 over three years), LCS (which would increase 10.1 percent or 1,680 over three years), and other sea turtles (which would increase 7.1 percent or one sea turtle over three years) (Table 4.21 and Table 4.22). The net ecological benefit of combining the closures with redistribution of effort would be an 8.4 percent decline in leatherback sea turtle interactions (~41 leatherback sea turtles from 2001 – 2003, or 14 per year), a 3.1 percent decline in loggerhead interactions (~ six loggerheads from 2001 – 2003, or two per year), a 13.6 percent decline in BFT discards (~220 BFT from 2001 – 2003, or 73 per year), a 1.7 percent decline in white marlin discards (~53 white marlin from 2001 – 2003, or 18 per year), and a 6.7 percent decline in blue marlin discards (~164 blue marlin from 2001 – 2003, or an average of 55 per year) (Table 4.21 and Table 4.22). Thus, the overall benefit would be greater for a seasonal closure than a year-round closure. In particular, the seasonal closure would potentially decrease leatherback and loggerhead sea turtle interactions, BFT discards, and blue and white marlin discards. However, the overall reduction in bycatch for most species was relatively low when combining closures, resulting in some ecological benefit to most species. Although discards of some species may decline with combined seasonal closures of alternatives B2(a) and B2(b), the positive ecological impacts would be offset by an increase in discards of other species. In addition, NMFS must also consider the social and economic impacts of such combination of closures (see discussion below).

With redistribution of effort, combining alternative B2(d) and B2(e) year-round would increase discards of white marlin, spearfish, pelagic sharks, LCS, and loggerhead sea turtles (Table 4.5 and Table 4.23). Discards of pelagic sharks and LCS, in particular, are predicted to increase by 65 percent and 102 percent, respectively, because these species are discarded at much higher rates in the Atlantic than in the Gulf of Mexico. Redistributing a large amount of effort from the Gulf of Mexico into the Atlantic would thus increase discards of these and other species. The only species for which there would be a substantial positive benefit would be BFT and leatherback sea turtles; 35.2 fewer dead discards of BFT are predicted, and leatherback sea turtle interactions would decrease by 30.2 percent over three years or an average of 50 fewer interactions per year (Table 4.5, Table 4.15, Table 4.23, and Table 4.24).

In addition to proposing new closed areas, NMFS initially considered modifying current or existing time/area closures (alternatives B3(a) and B3(b); see Section 2.1.2). In general, closed areas considered for modification (*i.e.*, partial re-opening) were chosen based on examining the HMS logbook and POP data from 1997 through 1999. The data were analyzed in GIS, allowing NMFS to identify areas associated with minimal bycatch within current time/area closures for re-opening (*e.g.*, Figure 4.3, Figure 4.14, and Figure 4.15). The overall goal was to modify existing areas, if possible, using the latest analysis techniques and technology available to NMFS, while minimizing bycatch and maximizing catch of retained species. This is especially pertinent for target species such as swordfish, where the United States is currently not fully utilizing its swordfish quota. In addition, due to the natural variability of many of the HMS fisheries, it may be necessary to change or refine the boundaries of time/area closures over time to reduce bycatch of non-target species.

Given that fishing effort and landings have declined in recent years, NMFS considered modifying existing closures to increase the opportunity to harvest the swordfish quota (Figure 4.3). In addition, if new time/area closures were to be implemented, then NMFS wanted to consider possible ways to offset those additional economic impacts by lifting restrictions in areas that had minimal bycatch. Originally four modifications to existing time/area closures were considered: B3(a) (the Charleston Bump), B3(b) (the Northeastern United States (NEC)), B3(c) (the Florida East Coast (FEC)), and B3(d) (DeSoto Canyon) (Figure A.2 in Appendix A). However, only alternatives B3(a) and B3(b) were further analyzed because they minimized bycatch while maximizing retained catch when compared to the other two alternatives (see Chapter 2 and Tables A.22 through A.27 in Appendix A). For each modification further analyzed, NMFS considered the bycatch and retained species catch that would be affected by re-opening a portion of a current closure (Table 4.25 through Table 4.30). In addition, NMFS considered the size of swordfish caught in the portions that would remain closed to the size of swordfish in the areas that were considered for reopening (Table 4.31).

Alternative B3(a) would modify the Charleston Bump time/area closure boundary to include only those areas shoreward of the axis of the Gulf Stream. The remaining areas seaward of the axis of the Gulf Stream would be reopened from February 1 through April 30. The B3(a) modification area (*i.e.*, the hatched area in Figure 4.3) was chosen because a minimal increase in bycatch would be expected with the 0.5 percent predicted increase in fishing effort associated with this re-opening, based on 1997 – 1999 logbook data and fishing practices from that time. For instance, the largest increase in discards would be for blue marlin (0.7 percent; Table 4.25) whereas no increase is predicted for interactions for leatherback or other sea turtles (Table 4.25). In addition, there was minimal increase in retained catch associated with modifying the Charleston Bump. There was a predicted increase in swordfish catches of 1.1 percent and yellowfin tuna catches of 0.16 percent (Table 4.27). The majority of the bycatch from 1997 – 1999 occurred in the portion that would remain closed (*i.e.*, the shaded area of Figure 4.14 and Figure 4.15; Table 4.25). For instance, the highest increase in bycatch would be expected for sailfish (3.0 percent), spearfish (2.4 percent), and white marlin (2.0 percent) (Table 4.25). On average, the area considered for re-opening in B3(a) would have an increase in bycatch of 0.5 percent whereas the predicted average bycatch associated with the area that would remain closed was 2.7 percent (Table 4.25). Thus, by using refined GIS maps (see Figure 4.14 and Figure 4.15) that were not available to NMFS when the time/area closures were first implemented, NMFS is now able to identify and refine areas of higher bycatch within current time/area closures.

As described above, NMFS considered re-opening existing closures in conjunction with new time/area closures (Table 4.5). Such combinations would help balance social and economic impacts of additional closures, while mitigating any potential negative ecological impacts of opening or modifying existing time/area closures. Year-round closures of B2(a) and B2(b) in combination with the B3(a) modification would potentially result in increases of bycatch of all species considered except sea turtles and BFT. Leatherback sea turtles interactions and BFT discards would decline by slightly more than 20 percent (Table 4.5). However, seasonal closures of the B2(a)/B2(b) in conjunction with the B3(a) modification would result in a decrease, albeit small (on average, 5.5 percent), in bycatch of all species considered except sailfish (Table 4.5). This could result in small, but net positive ecological impacts. Similarly, NMFS considered B3(a) in conjunction with the B2(d)/B2(e) year-round closure. This combination could result in decreases of discards for blue marlin, sailfish, spearfish, leatherback sea turtles and BFT (Table 4.5). However, it could also result in increases of discards for white marlin, and loggerhead sea turtles (Table 4.5). Therefore, the ecological effects of such a combination would be variable.

Alternative B3(b) would modify the existing Northeastern U. S. closed area to allow the use of PLL gear in areas west of 72° 47’ W Longitude during the month of June. This area was mainly considered as a way to refine the Northeastern U. S. closed area and re-open areas where there were few swordfish or BFT discards (Figure 4.14 through Figure 4.16; Table 4.28). Based on fishing effort from 1997 – 1999 before the closures went into effect (taken from logbook data from 1997 – 1999), there could be an estimated 0.2 percent increase in fishing effort associated with this modification. However, this modification could result in additional fishing effort given management actions that have taken place since 2000 (*i.e.*, time/area closure put into place in 2000). While there is a predicted minimal increase in retained catch, there would be virtually no increase in bycatch associated with this modification (Table 4.26 and Table 4.28). For example, there is only one predicted BFT discard associated with this modification (Table 4.28). Discards of sailfish and sea turtles are not predicted to increase. Thus, such a modification would have minimal to no ecological impact.

Since the bycatch associated with B3(b) was essentially zero (Table 4.5 and Table 4.26), combinations of this modification with any time/area closure would mirror the benefits in bycatch reduction associated with the particular time/area closure. For instance, seasonal closures of B2(a)/B2(b) in conjunction with the B3(b) modification could result in small decreases (on average, six percent), in bycatch of all species considered except sailfish (Table 4.5). This could result in a small, but net positive ecological impact. NMFS also considered a combination of B3(b) with year-round closures of B2(a)/B2(b). However, this combination resulted in a higher number of discards (with the exception of sea turtles and BFT) than the combination with seasonal closures (Table 4.5). When B3(b) was considered in conjunction with the B2(d)/B2(e) closure, there could be increases in bycatch for white marlin, spearfish, and loggerhead sea turtles (Table 4.5). Decreases in bycatch could be seen for blue marlin, sailfish, leatherback sea turtles, and BFT. So, as with the B2(d)/B2(e) closure, this modification in combination with this closure could have variable ecological effects.

As described in Chapter 2, alternative B4 would implement year-round complementary HMS management measures in the Madison-Swanson and Steamboat Lumps Marine Reserves, consistent with the recommendations of the Gulf of Mexico Fishery Management Council (GMFMC) (Figure 4.4). Specifically, this alternative would prohibit all HMS-permitted vessels from fishing or deploying any fishing gear in the marine reserves from November through April. From May through October, surface trolling would be the only HMS fishing activity allowed. Surface trolling is defined as fishing with lines trailing behind a vessel that is in constant motion, at speeds in excess of four knots, and with a visible wake (in accordance with the Southeast regional regulations, 622.34(k)(5), NMFS is adopting the same definition for surface trolling in the final rule associated with this document). Such surface trolling may not involve the use of down riggers, wire lines, planers, or similar devices. The two marine reserves are located shoreward of the Desoto Canyon Closed Area (see Section 2.1.2).

At a July 14 – 17, 2003, meeting, the Gulf Council approved a six-year extension of these two marine reserves, originally implemented in 2000, to protect spawning aggregations of gag grouper. An Environmental Assessment (EA) describing the ecologic, economic, and social impacts associated with the marine reserves was prepared and submitted to the Secretary in August 2003. On September 3, 2003, NMFS received a formal request from the Gulf Council for the Secretary to implement "compatible" regulations for HMS fisheries in these two areas. The final rule, effecting non-HMS fishing activities, published in the Federal Register on May 4, 2004 (69 FR 24532), and became effective on June 3, 2004. It will expire on June 16, 2010. The complementary HMS management measures described above in alternative B4 would similarly expire on June 16, 2010.

The purpose of this alternative is to implement compatible HMS regulations in the Madison-Swanson and Steamboat Lumps Marine Reserves to provide, as described in the EA prepared by the GMFMC (August 2003), protection for spawning aggregations of gag grouper to prevent overfishing, improve spawning success, protect a portion of the offshore population of male gag grouper, and facilitate continued evaluation of the effect and usefulness of marine reserves as a fishery management tool. These two marine reserves were originally implemented in 2000 by the Gulf Council (for Gulf species) in response to a determination by NMFS that gag grouper were experiencing overfishing and scientific information indicating that the proportion of male gag had declined substantially since the 1970s. A four-year timeframe for the reserves was initially established in 2000, so that their effects could be evaluated before deciding whether to continue with the marine reserves. In 2002, NMFS reclassified gag grouper as neither overfished, nor undergoing overfishing. However, the stock was not at optimum yield. Therefore, the Gulf Council voted to extend the marine reserves an additional six years, for a total of ten years, and to request compatible HMS management measures. This alternative would significantly reinforce the protections afforded gag grouper and other Gulf reef species by closing a potential loophole whereby vessels can currently fish for HMS in the marine reserves. Closing this loophole should provide a better opportunity to evaluate the effectiveness of the marine reserves as a fishery management tool.

As described in the EA (GMFMC, 2003), anticipated conservation benefits of the marine reserves include the protection of seasonal spawning aggregations of gag grouper, and the year-round protection of a portion of the male gag grouper population. Other reef species that may also benefit from the marine reserves include red grouper, snowy grouper, red snapper, silk snapper, vermillion snapper, scamp, speckled hind, red porgy, knobbed porgy, triggerfish, greater amberjack, honeycomb moray, and bank sea bass. A complete description of the ecological benefits for Gulf reef fish is provided in the EA (GMFMC, August 2003) and is not repeated here. Although this alternative is not specifically intended to provide protection for HMS, it could provide some minor ancillary conservation benefits for HMS as a result of the year-round prohibition on HMS fishing activities in the reserves (except for surface trolling from May through October). Any positive ecological impacts on HMS are expected to be minimal because there has been little reported or observed HMS fishing effort in the area in recent years; however, such complementary management measures would help prevent future potential increases in fishing efforts, thus offering protection to the gag grouper spawning aggregations until 2010. From 1997 to 2003, only one PLL set and one bottom longline set were reported in the HMS logbook in these areas. Both sets occurred in the Madison-Swanson site. Four swordfish were kept on the PLL set, and eight swordfish were discarded. There were no reported HMS caught on the bottom longline set, and there were no new PLL or bottom longline sets recorded in 2004. One bottom longline vessel carried an observer onboard in the Madison-Swanson site. The observed set occurred in 1996 and kept eight sandbar sharks (CSFOP data). No new sets were recorded for the CSFOP in 2004. In summary, NMFS anticipates positive ecological benefits for gag grouper and other Gulf reef species. Any conservation benefits for HMS, however, are expected to be minor for several reasons, but are expected to enhance the protection for spawning gag grouper aggregations. Because the closure areas are relatively small, any HMS fishing activity that otherwise would have occurred in these areas would likely relocate to nearby open areas with similar catch rates. Furthermore, because possession of Gulf reef species is already prohibited within the areas (except when transiting), bottom longline sets targeting both sharks and Gulf reef species have already likely decreased since initial implementation of the reserves in 2000. Finally, recreational and charter/headboat fishing trips for HMS in the marine reserves are not likely to be significantly curtailed due to the allowance for surface trolling from May through October, which are the prime fishing months.

Preferred alternative B5 would establish criteria for regulatory framework adjustments to implement new time/area closures or make modifications to existing time/area closures. These adjustments would allow NMFS would to implement and/or modify time/area closures through proposed and final rulemaking through a framework action rather than adjusting the HMS FMP amendment. The criteria would provide a more definitive process for the establishment or modification of time/area closures while allowing for greater transparency and predictability in the decision making process. Criteria that would be considered may include, but are not limited to, the following: any ESA-related issues, concerns, or requirements including applicable Biological Opinions; bycatch rates of protected species, prohibited HMS, or non-target species both within the specified or potential closure area (s) and throughout the fishery; bycatch rates and post-release mortality rates of bycatch species associated with different gear types; applicable research; new or updated landings; bycatch and fishing effort data; social and economic impacts; and the practicability of implementing new or modified closures, including consistency with the FMP, Magnuson-Stevens Act, ATCA, and other applicable law. If the species is an ICCAT managed species, NMFS would need to determine the overall effect of the United States' catch on that species before implementing time/area closures. In these cases, other factors that NMFS would consider before implementing time/area closures include, but are not limited to, gear types and the location and timing of a closed area. NMFS would attempt to balance the ecological benefits with economic and social impacts. NMFS would also consider alternatives to closed areas, such as reducing quotas, mandatory gear modifications, or alternative fishing practices such as designated fishing days. Thus, before the implementation of a time/area closure, NMFS would determine that such a closure would be the best option for a given set of management goals, consistent with the FMP, the Magnuson-Stevens Act, and applicable law.

Ultimately, the criteria are aimed to develop smaller, more focused time/area closures that maximize bycatch reduction and catch of retained species. While new time/area closures or modifications to current closures may have ecological, social, and economic impacts, the criteria themselves would not be expected to have positive ecological impacts and minimal, to the extent practicable, economic and social impacts.

The primary goals of time/area closures are to maximize the reduction of bycatch or non-target and protected species while minimizing the reduction in the catch of target species. However, closures are not the only means of addressing bycatch and in some cases may increase bycatch (see Table 4.5). Bycatch in and of itself would not necessitate implementation of a time/area closure. However, if the HMS stock was either overfished and/or experiencing overfishing; the bycatch is a prohibited, threatened or endangered species; no other option exists to reduce interactions in the time period required; and analyses indicate that an appropriate time/area could be designed that would not significantly increase bycatch of other species, then NMFS may consider a time/area closure. In such cases, NMFS could include time/area closures as part of a rebuilding plan for overfished species and/or serve as a method for decreasing interactions with protected species.

If the public believes that modification to an existing time/area closure or the establishment of a new time/area closure is warranted based on these criteria, they can submit a petition for rulemaking to NMFS. A petition for rulemaking should contain sufficient information for NMFS to consider the substance of the petition. For a petition regarding a new time/area closure or a change or modification to an existing time/area closure, pursuant to 5 U.S.C. § 553(e), the petition should, at a minimum:

- Indicate the area that should be considered as a time/area closure or the current time/area closure that should be modified
- Identify which criteria warrant the addition or modification of a time/area closure
- Provide data, information, etc., relevant to those identified criteria
- State the resources necessary to develop the proposed regulations
- Explain the interest of the petitioner in the action requested
- Indicate the size of the population affected (*i.e.*, who is affected by the action)
- Indicate the public interest in the proposed regulation
- Explain the importance of the action requested to promoting NMFS' established priorities and policies.

During the comment period, NMFS heard from commenters and the peer reviewers that the Agency should design a "decision matrix" that could help to guide the choices that NMFS would have to make between different closures and different species. This request is interpreted to mean that NMFS should decide whether, for example, it is more important to protect spawning BFT during particular times and areas than leatherback sea turtles. If NMFS decided that were the case, then an area would be closed to protect spawning BFT even though it could potentially increase takes of leatherback sea turtles. Related to this idea of a decision matrix, some commenters noted that NMFS should set bycatch reduction goals. For example, NMFS would need to reduce BFT discards by some set percent; under this concept, NMFS would need to find ways to reduce BFT discards by the appropriate percent, possibly to the detriment of other species. Once that percent reduction was made, NMFS would no longer need to reduce BFT discards. Similarly, if NMFS implements measures that reduce BFT discards by more than the decided amount, NMFS could potentially relax some of the measures to bring the reduction down to the pre-decided level. Finally, NMFS received comments from commercial interests indicating that the bycatch reduction goals of the existing closures have already been met and, therefore, the Agency should reopen at least portions of the current closures.

During the rulemaking process that implemented the East Florida Coast, the DeSoto Canyon, and the Charleston Bump closures, NMFS heard similar comments from all interested parties (commercial, recreational, and environmental) that the Agency should establish bycatch reduction goals for all species. At that time, NMFS did not establish such goals, and stated that establishing pre-determined target reduction goals for specific species is inappropriate because it does not consider the impact on the remaining portion of the catch. This statement remains valid. While not a formalized decision matrix, NMFS used the analyses in the time/area closure section, which considered all species, to evaluate the effects of the potential time/area closures, including all species for a combination of closures. NMFS used the results of the analyses to guide the Agency in determining which management measures are appropriate at this time. NMFS, however, cannot place more value on one species over another species and believes that setting pre-determined or pre-set reduction goals in bycatch and/or discards will compromise NMFS' ability to consider multiple species. Consideration of the overall catch is critical when implementing a multispecies or ecosystem-based approach to management. Furthermore, while the Magnuson-Stevens Act provides NMFS the authority to manage all species, NMFS must balance the impacts of management measures on all managed species and my choose protections for one species to the detriment of protected or overfished species (*e.g.*, choosing to protect BFT even if sea turtle interactions may increase substantially). National Standard 1, which requires NMFS to prevent overfishing while achieving on a continuing basis, the optimum yield from each fishery for the United States fishing industry, clearly applies to all species and all fisheries. Similarly, National Standard 9, which requires NMFS to minimize bycatch and bycatch mortality to the extent practicable, applies to all species and fisheries. By not choosing a specific threshold or establishing a decision matrix, NMFS retains the flexibility to balance the needs of all the species encountered and the fishery as a whole. If NMFS is given a specific goal (*e.g.*, a jeopardy conclusion regarding the PLL fishery and leatherback sea turtles), this flexibility allows NMFS to close certain areas or take other actions to protect that specific species while also protecting, to the extent practicable, the other species and the rest of the fishery. Absent this flexibility, NMFS might potentially have to implement more restrictive measures to protect one species causing potential cascade effects (*e.g.*, closing one area may increase the bycatch of another species which could result in closing another area, etc.). This approach also provides NMFS with the flexibility to re-examine the need for existing closures and modify them appropriately based on the analyses rather than the attainment of a specific goal (*e.g.*, NMFS would not have to wait for 30 percent to be met; it could open the closure at 25 percent, depending on the result of reducing bycatch of other species or other consideration, as appropriate). This does not preclude NMFS from considering the establishment of a more formalized decision matrix in the future if such a matrix could be designed that would provide for the flexibility to consider all the species involved. This may be more appropriate when NMFS has a longer temporal dataset on the simultaneous effect of circle hooks and the current time/closures. At this time, NMFS believes that the criteria contained in the preferred alternative B5 provides the guidance needed, consistent with the Magnuson-Stevens Act and this FMP, to help NMFS make the appropriate decisions regarding the use of time/area closures in HMS fisheries.

Alternative B6 would prohibit the use of all bottom longline gear targeting HMS in an area southwest of Key West to protect endangered smalltooth sawfish (Figure 4.5). Smalltooth sawfish were listed under the ESA in 2001, but critical habitat has not yet been designated. NMFS has assembled a Smalltooth Sawfish Recovery Team (SSRT) comprised of researchers, managers, and representatives from constituent groups to develop a recovery plan for the U.S.

population of smalltooth sawfish. Once a plan is completed, NMFS may consider time/area closures to reduce sawfish interactions. Preliminary analysis of some of the SSRT data (Burgess, unpublished data) documented approximately 178 smalltooth sawfish interactions, mainly in state and Federal waters off the state of Florida, between 1990 and 2004. Of the 178, three (1.7 percent) were caught on hook and line, five (2.8 percent) were caught in shrimp trawl gear, and three were observed while people were swimming. All other interactions (167 out of 178 or 94 percent) occurred with shark bottom longline gear. The data represents a comprehensive data set that the SSRT has accumulated over time; however, it is preliminary and anecdotal in nature and will be formally analyzed by the SSRT. Therefore, NMFS focused on smalltooth sawfish interactions from the CSFOP, Gillnet, and POP, which represents more recent and well-documented data. In addition, most interactions with smalltooth sawfish have occurred with bottom longline gear. From 1994 – 2006, these combined observer programs only documented one interaction of smalltooth sawfish with gillnet gear in 2003 off the southeast coast of Florida, and only one smalltooth sawfish interaction was documented in the POP, which occurred during a bottom longline set. Therefore, since smalltooth sawfish seem to be much more susceptible to bottom longline gear, only bottom longline would be prohibited in this closure.

The interactions with smalltooth sawfish from 1994 to 2006 during the CSFOP are shown in Figure 4.5 (these interactions were specific to observed interactions from the CSFOP and bottom longline gear unlike the SSRT data). A total of 12 smalltooth sawfish were observed on bottom longline gear (out of 1,563 total observed sets) from South Carolina to the west coast of Florida. Given how widely dispersed and few in number the interactions with smalltooth sawfish were, NMFS tried to choose the smallest area possible that would encompass the highest number of interactions. The result was a 49 $nm^2$ area off the southwest tip of the Key West (Figure 4.5). This area encompasses 18 of the 1,563 total observed sets and is where five of the 12 smalltooth sawfish were observed caught with bottom longline gear from 1994 to 2006.

While this area is small compared to the other closures being considered for other species and could have a positive ecological impact percentage-wise (*i.e.*, upwards of 42 percent or five out of 12 observed interactions), it still translates into five individuals. In addition, this high percentage of bycatch reduction would depend on whether sawfish occur regularly in the area or whether the high number of interactions observed during 1997 was an anomaly. There have been no observed interactions in the area since 1997 (*i.e.*, nine years), and only a total of seven observed interactions occurred since 1997 through 2006 in different areas (1 in 1999, 1 in 2002, 1 in 2003, 2 in 2005 and 2 in 2006; Figure 4.17). Of the five observed sawfish interactions that occurred in this area on BLL gear, four were on a single set, highlighting the episodic nature of sawfish interactions. Additionally, 11 of 12 sawfish were released alive, and one was released in unknown condition. The one sawfish observed caught in the shark gillnet fishery was also released alive. Given the limited amount of data available, it is difficult to determine whether the area being considered would result in overall reduction in interactions, or whether sawfish exhibit a higher degree of mobility, and are as likely to be caught in other areas. If the latter is the case, then such a closure could redistribute effort into areas where there are higher interactions with smalltooth sawfish and cause increases in these interaction rates. The SSRT is currently in the process of identifying sawfish critical habitat, which may be helpful in determining an appropriate closure area in the future.

Alternative B7 would prohibit the use of PLL gear in all HMS fisheries. Prohibiting the use of PLL gears would likely have positive ecological benefits on HMS, non-target HMS, and protected species. The number of discards would potentially be reduced by 1,047 white marlin, 816 blue marlin, 343 sailfish, 141 spearfish, 11,340 pelagic sharks, 5,524 LCS, 165 leatherback sea turtles, 60 loggerhead sea turtles, and 539 BFT annually (Table 4.11; annual discards were estimated by dividing the total from 'All Areas' by three). The number of retained species would also be reduced by a significant amount. The number of fish kept would be reduced by 42,500 swordfish, 200 BFT, 55,734 yellowfin tuna, 12,378 bigeye tuna, and 75, 385 BAYS annually (Table 4.11). However, elimination of this retained catch would result in substantial negative social and economic impacts as described below. In addition, any ecological benefits may be lost if ICCAT reallocates U.S. quota to other countries that may not implement comparable bycatch reduction measures as the United States. The PLL fishery has undergone many management measures to reduce bycatch including circle hooks implementation, live bait restrictions in the Gulf of Mexico, no targeted catch of billfish and BFT, time/area closures, and safe handling and release protocols for protected resources. These restrictions have been successful. Methods that have been employed and designed by U.S. PLL fishermen, such as circle hooks and safe handling and release protocols for protected resources, are being transferred around the world to reduce bycatch world-wide. Therefore, this alternative could ultimately provide support for the fisheries of other countries that do not implement conservation and bycatch reduction measures.

Lastly, the alternatives considered in this section are not expected to have any negative impacts on essential habitat or protected resources. The preferred alternative, B4, will help protect spawning aggregations of gag grouper, and therefore, would be expected to have a positive impact on essential fish habitat for these species. In addition, any potential impacts to protected resources (*i.e.*, leatherback and loggerhead sea turtles) were discussed for each alternative. However, since no closures were preferred at this time, except the Madison-Swanson and Steamboat Lumps Marine Reserves, and the other preferred alternative, B5, would establish criteria to implement and/or modify closed areas in the future, no impacts on protected resources are anticipated at this time.

*Social and Economic Impacts*

Each of the alternatives considered for time/area closures would have varying degrees of social and economic impacts. To determine the potential impacts, NMFS estimated the amount of fishing effort (number of hooks), total number of vessels, landings of retained species, and total loss or gain in gross revenues for each species that would be affected by any new closure with and without redistribution of fishing effort. A similar approach was used to predict the economic impact of any potential modifications to existing closures. To estimate the loss (or gain) in gross revenues for a single species, NMFS first estimated the total weight (lb dw) of each species harvested by PLL gear only (Table 4.32) based on data from Section 3.4.5, and then calculated the total weight lost or gained for each species as a result of the closure. Total weight for each species was then multiplied by the average ex-vessel price ($/lb dw) by area based on 2003 prices (Section 3.5.1). The gross revenues for all species were then added together to estimate a total annual loss or gain in gross revenues as a result of the closure. As described above, not considering redistribution of fishing effort assumes that all fishing effort within the time/area closures alternative is eliminated (and not transferred outside the closure). While this may not be realistic, it provides a worst-case scenario of the potential economic impacts of any new closure(s). The redistribution of effort analysis, on the other hand, assumes that all fishing effort is displaced into open areas, which also may not be realistic given that a closure of a prime fishing area may force some fishermen out of business, to switch fisheries, or that some fishermen may relocate nonrandomly, etc. Overall effort may also increase slightly if there is a need to compensate for increased operating costs. Therefore, the actual result may lie somewhere in between. NMFS considered both estimates because they provide a range of potential economic impacts depending upon the response of the PLL industry. As mentioned above, the NEFMC is aware of different econometric optimization models to predict impacts of time/area closures (*e.g.*, NEFMC, 2003). However, such models are not currently designed to be used for the current HMS PLL fishery. Therefore, NMFS chose to evaluate the economic impacts of different closures based on the redistribution of effort model described in this rulemaking.

During the Draft HMS FMP, 2004 ex-vessel prices and 2004 dollars were not available. However, subsequent to the Draft HMS FMP, these values have become available, and NMFS analyzed the potential cost and/or gain to the PLL fishery associated with the implementation of each closures and modification. Total weight for each species was multiplied by the average ex-vessel price ($/lb dw) by area based on 2004 prices (Section 3.5.1). The total 2004 annual loss or gain to the fishery was calculated by converting the 2003 total gross revenues into 2004 dollars (2003 value was multiplied by 1.0266). Therefore, the total gain or loss associated with 2004 is similar to what was seen in 2003. These results are shown in Table 4.33, Table 4.34, and Table 4.35.

The estimates of gross revenues lost or gained as a result of a closure do not take into account additional costs that may be incurred by having to relocate to new fishing grounds. These costs may be substantial. For example, alternative B2(d), a closure of nearly the entire Gulf of Mexico, would likely require fishermen to move to the Atlantic, resulting in relocation costs, additional travel and fuel costs, additional crew costs, losses to fish dealers and distributors, and other associated social and economic costs. Other impacts may include intense competition for existing resources as fishermen are forced into smaller open areas resulting in potential gear conflicts, shifting to other fisheries, or fishermen going out of business. There may also be a concern for species whose landings are predicted to rise substantially with redistribution of effort, and whether those species can sustain a large increase in harvest.

NMFS also examined the impacts of each of the alternatives on gross vessel revenues based on the number of vessels that reported fishing in potential closed areas from 2001 to 2003 (Table 4.36), as well as the number of vessels per state potentially impacted by a particular closure (Table 4.37). This information was also updated with finalized data from January through June 2004 when J-hooks were still being used. However, since this is only six months of data, the information is provided in Table 4.36 and Table 4.37, but is not included in the discussion below.

Alternative B1, the No Action alternative that would maintain existing closures has, and would likely continue to have, negative economic impacts on the PLL industry revenues, relative to pre-closure revenues. As described earlier, when comparing pre- and post-closure logbook reported data, the existing closures may have contributed to the reported 15 percent decline in fishing effort (Table 4.8), and the ten percent decline in the number of directed and incidental limited access permits from 1,275 permits in 2001 to 1,144 permits in 2005 (Table 3.92 in Section 3.9.2). The number of retained species kept has declined by 37.4 percent for bigeye tuna, 27.9 percent for swordfish, 23.5 percent for yellowfin tuna, and 25.1 percent for BAYS tunas (Table 4.6). In addition, there are a number of other species that are frequently retained by PLL fishermen, and landings of these species have also been declining (Table 4.7). For example, the number of pelagic sharks kept declined by 18.9 percent, LCS by 38.9 percent, dolphin by 25.9 percent, and wahoo by 25 percent. Although an exact figure is not available, the estimated annual loss in gross fishery revenues when compared to other alternatives with similar reductions in retained species may have been in the millions of dollars. However, the decline in landings reflect the period immediately after the closures were implemented, and do not reflect continuing loss of revenue into the future for the fishery.

Another factor which may have impacted the landings and effort is the implementation of a mandatory circle hook requirement for the PLL fishery in 2004 (69 FR 40734). Preliminary analyses of the logbook data from July to December of 2004 against the same time period for 1997 – 1999 (pre-closures) and 2001 – 2003 (post-closures) indicate that landings and discards of most retained species and bycatch have declined (Tables A.34 and A.35 in Appendix A). Percent declines reported in this analysis should be considered preliminary as it is based on only six months of data post circle hook implementation.

A number of factors may be contributing to the decline in permits and overall fishing effort including, but not limited to: (1) the time/area closures implemented in 1999 to 2002; (2) a decline in ex-vessel prices for swordfish and some tunas (Table 3.65 in Section 3.5) in combination with increasing fuel and operational costs that may have forced fishermen to curtail fishing effort; and (3) fishermen transitioning to other fisheries to adjust for declining revenues. It is unclear at this point whether the decline in fishing effort and number of permits will continue, or whether the fishery has stabilized at its current level. Given the North Atlantic swordfish stock is estimated to be at 94 percent of $B_{MSY}$ (SCRS, 2004), overfishing is no longer occurring, and there have been large underharvests in recent years resulting in an ever larger quota, it is possible that effort may stabilize and possibly increase despite the existence of current time/area closures.

Alternative B2(a), a closure in the Gulf of Mexico from May through November each year, would potentially impact a total of 61 vessels that reported fishing in the area from 2001 – 2003, or an average of 46 vessels per year (Table 4.36). A total of 2,918 sets were reported from 2001 – 2003, or an average of 973 sets per year (Table 4.36). Without redistribution of effort, alternative B2(a) would potentially result in an 11.4 percent decline in fishing effort, and reductions in landings of retained species ranging from a minimum of 1.1 percent for bigeye tuna to a maximum 14.3 percent for yellowfin tuna. For yellowfin tuna, the most lucrative species affected by a Gulf of Mexico closure, this would amount to a loss of $1,796,654 in annual gross revenues based on Gulf of Mexico prices (Table 4.33). Swordfish landings would potentially decrease by 3.1 percent for a loss of approximately $423,382, BFT landings would decrease by 6.7 percent for a loss of $60,791, and bigeye tuna landings would decrease by 1.1 percent for a loss of approximately $18,190 (Table 4.33). Thus, the combined total loss in gross revenues for alternative B2(a) without redistribution of effort would be approximately $2,299,018 annually (Table 4.33), or $49,978 per vessel annually ($2,299,018 / 46 vessels). Of the three major states bordering the Gulf of Mexico with vessels permitted to fish for HMS with PLL gear (Florida, Louisiana, Texas), Louisiana had the highest number of vessels (40 out of 61, or 66 percent) that fished in the area from 2001 – 2003 (Table 4.37). The vessels with homeports in Louisiana also reported a majority (88 percent) of all sets in the area. There were some changes in anticipated losses from B2(a) when 2004 prices were considered. The ex-vessel price for BFT went down in the Gulf region for 2004, unlike the price of swordfish, yellowfin or bigeye tuna (Table 4.33). Therefore, the loss associated with BFT was less using 2004 ex-vessel prices, whereas the greatest loss was anticipated for yellowfin tuna followed by swordfish (Table 4.33).

With redistribution of fishing effort, alternative B2(a) is predicted to result in an increase in all retained species landings and gross revenues except yellowfin tuna, which are predicted to decrease by 1.1 percent for a loss of approximately $138,204 annually (Table 4.33). Swordfish landings, on the other hand, would potentially increase by 9.1 percent for a gain in gross revenues of $1,242,832. Similarly, bluefin and bigeye tuna gross revenues are predicted to increase by $27,871 and $42,997 respectively (Table 4.33). Thus, the combined total gain in gross revenues for alternative B2(a) with redistribution of effort would be approximately $1,175,496 annually (Table 4.33), or $25,554 per vessel annually ($1,175,496 / 46 vessels). The analysis based on 2004 prices indicated that the largest gain in gross revenues would come from increase swordfish catch whereas the biggest loss in gross revenues would be from decreased yellowfin tuna landings (Table 4.33). Gross revenues from increased landings of BFT would be less in 2004 compared to 2003, but there would be an increase in gross revenues with 2004 ex-vessel prices associated with bigeye tuna landings (Table 4.33).

These results reflect differences in abundance and CPUEs for different HMS in different regions, and the variability in landings and economic estimates with redistribution of effort. For example, the entire Gulf of Mexico accounted for 68.8 percent of all yellowfin tuna landings, 57.6 percent of all BFT landings, but only 22.8 percent of all swordfish landings from 2001 – 2003 (Table 4.38). As a consequence, with redistribution of effort outside of the Gulf of Mexico, yellowfin tuna landings would be expected to decrease and swordfish landings to increase. However, one potential economic incentive would be reducing the interaction with non-target HMS and protected species. For instance, the Gulf of Mexico also accounted for the highest interactions of non-target HMS species, such as 62.8 percent of the leatherback sea turtle interactions (Table 4.39). Moving fishing effort out of this area could reduce interactions with protected resources; however, this may result in unanticipated interactions with other non-target and/or protected species in the Atlantic and high seas. In the event that effort is displaced into open areas of the Gulf of Mexico only, NMFS analyzed the landings from alternative B2(a) in comparison to landings from the Gulf of Mexico only (as opposed to overall landings from the Atlantic and Gulf of Mexico). Without redistribution of effort, landings of all retained species are predicted to decrease with a total loss in gross revenues of $5,003,298 (Table 4.35), or $108,767 per vessel annually ($5,003,298 / 46 vessels). This equated to -$5,136,386 in 2004. With redistribution of effort, there would be an increase in all retained species kept except bigeye tuna resulting in a predicted increase in gross revenues of $679,212 (Table 4.35), or $14,765 per vessel annually ($679,212 / 46 vessels). Incidentally caught BFT and targeted bigeye tuna are the only two species for which landings are predicted to decrease by 0.8 percent and 8.7 percent, respectively, with redistribution of effort in the Gulf of Mexico only. However, since the 2004 ex-vessel price of BFT went down in the Gulf of Mexico, the loss associated with decreased BFT landings was less than in 2003. However, the loss associated with bigeye tuna using 2004 ex-vessel prices was larger, due to the increase in ex-vessel prices for bigeye tuna in the Gulf of Mexico in 2004. Thus, the predicted economic impacts to gross revenues for the fleet could range from a loss of approximately $5.1 million to a gain of approximately $1.2 million (Table 4.35).

The apparent increase in landings and gross revenues for several of the species with redistribution of effort in the Gulf of Mexico only is somewhat surprising, and may point to the fact that tunas other than bluefin and bigeye tuna are more likely to be caught outside the alternative B2(a) area. This may indicate that fishermen are targeting not only yellowfin tuna, which has the highest overall economic value, but also BFT. In other words, even though catches of yellowfin tuna may be higher outside the alternative B2(a) area, fishermen may be targeting the area for the increased opportunity to catch an occasional BFT. The incidental catch limit in all areas, at all times, is 2,000 lb to retain one BFT, 6,000 lb to retain two BFT, and 30,000 lb to retain three BFT. The analysis of both the observer program and logbook data indicates that the central Gulf of Mexico is one of the prime areas for BFT discards, as well as bluefin and yellowfin tuna landings. NMFS is concerned about the potential negative economic impacts of closing this prime fishing ground for tunas as well as indications that PLL vessels may be targeting BFT (as incidental only species). By comparison, alternative B2(b) could result in a much higher reduction in BFT discards, with a much lower decrease in overall landings than alternative B2(a). Additionally, anecdotal information suggests that a proportion of the Gulf of Mexico PLL fishing fleet is comprised of Vietnamese fishermen, who may be reluctant to leave their traditional homeports and would likely stay in the Gulf of Mexico (Wilson *et al*., 1998; NMFS, 2004), perhaps making a redistribution model of effort in the Gulf of Mexico more realistic. Closing this area could thus have potential social impacts in addition to economic impacts.

Alternative B2(a), and most of the other time/area closures described in this section, could have numerous social impacts ranging from disruption of local fishing communities to relocation of vessels and homeports, loss of crew, and other social hardships associated with loss of income. A majority of the vessels (66 percent) impacted by alternative B2(a) have a homeport in Louisiana (Table 4.37), whereas 23 percent have a homeport in Florida and 11 percent have a homeport in Texas. Depending on the extent of redistributed fishing effort, revenues could range from a loss of $5.1 million to a gain of approximately $1.2 million (Table 4.35). Thus, the homeports and communities associated with those homeports in TX, LA, and FL could experience either loss of fishery revenues and social hardship associated with the loss, or they could potentially benefit from increased revenues. Given that this is the smallest closure considered for the Gulf of Mexico, the types of impacts described above would be similar for most other alternatives, although the scale of impacts from other alternatives considered would likely be greater.

Alternative B2(b), would potentially impact a total of 20 vessels that fished in an area of the Northeast from 2001 – 2003, or an average of 10 vessels per year. There were a total of 226 sets reported from 2001 – 2003, or an average 75 sets per year (Table 4.36). Without redistribution of effort, alternative B2(b) would potentially result in a 0.9 percent decrease in fishing effort, with reductions in landings of retained species ranging from a minimum of 0.3 percent for yellowfin tuna to a maximum 1.8 percent for incidentally caught BFT (Table 4.15). Swordfish landings would potentially decrease by 1.5 percent for a loss of approximately $231,252, yellowfin tuna landings would decrease by 0.3 percent for a loss of $27,102 and bigeye tuna landings would decrease by 1.5 percent for a loss of approximately $26,011. Thus, the combined total loss in gross revenues for a alternative B2(b) closure without redistribution of effort would be approximately $299,120 annually (Table 4.33), or $29,912 per vessel annually ($299,120 / 10 vessels). In general, the loss associated with decreased landings from B2(b) increased for all species when 2004 prices were considered (Table 4.33). This was due to an increase in ex-vessel prices for these species in 2004 in the North Atlantic region. Vessels with homeports in ten different states reported landings from the area in 2001 – 2003, with the highest number of vessels from New York (Table 4.37).

With redistribution of fishing effort, alternative B2(b) was predicted to result in a decrease in all retained species landings and gross revenues except yellowfin tuna, which are predicted to increase by 0.9 percent for a predicted gain of approximately $81,306 annually (Table 4.33). Swordfish landings would potentially decrease by 0.8 percent for a loss in gross revenues of $123,334, and bigeye tuna and incidental BFT gross revenues are predicted to decrease by $20,809 and $9,837 annually, respectively. Thus, the combined total loss in gross revenues for alternative B2(b) with redistribution of effort would be approximately $72,675 annually (Table 4.33), or $7,267 per vessel annually ($72,675 / 10 vessels). Using 2004 prices, a greater gain in gross revenues was predicted for yellowfin tuna with the consideration of redistribution of effort (Table 4.33). However, a greater loss was predicted for swordfish, BFT, and bigeye tuna, resulting in a total loss of $74, 608 for 2004 (Table 4.33).

Alternative B2(c), would potentially impact a total of 75 vessels that fished in the area from 2001 – 2003, or an average of 64 vessels per year. A total of 12,623 sets were reported from 2001 – 2003, or an average of 4,207 sets per year (Table 4.36). Without redistribution of effort, alternative B2(c) would potentially result in a 13.4 percent decrease in fishing effort, and reductions in landings ranging from a minimum of 0.2 percent for bigeye tuna (kept) to a maximum 29.0 percent for incidentally-caught BFT (kept) (Table 4.15). For yellowfin tuna, the most lucrative species affected by alternative B2(c), a 19.8 percent reduction in landings would amount to an estimated loss of $2,483,678 annually based on Gulf of Mexico prices (Table 4.33). Swordfish landings would potentially decrease by 2.8 percent for a loss of approximately $384,981, and incidental BFT landings would decrease by 29.0 percent for a loss of approximately $263,563 annually (Table 4.33). Thus, the total loss in gross revenues for alternative B2(c) without redistribution of effort would be approximately $3,136,229 annually (Table 4.33), or $49,003 per vessel annually ($3,136,229 / 64 vessels). As with B2(a), there were some changes in anticipated losses from B2(c) when 2004 prices were considered. The ex-vessel price for BFT went down in the Gulf region for 2004, unlike the price of swordfish, yellowfin or bigeye tuna (Table 4.33). Therefore, the loss associated with decreased BFT was less using 2004 ex-vessel prices whereas the greatest loss was anticipated for yellowfin tuna followed by swordfish (Table 4.33). Similar to alternative B2(a), a majority of the vessels that would be affected by the closure were from Louisiana (Table 4.37).

With redistribution of fishing effort, alternative B2(c) is predicted to result in a decrease in bluefin and yellowfin tuna landings of 18.3 and 11.0 percent respectively, for estimated losses of approximately \$166,040 and \$1,382,042 annually (Table 4.33). Swordfish and bigeye tuna landings would potentially increase by 21.1 and 11.4 percent respectively for a gain in gross revenues of approximately \$2,881,732 and \$188,520 annually, respectively. Thus, there would be a net gain in gross revenues for alternative B2(c) with redistribution of effort of approximately \$1,522,170 annually (Table 4.33), or \$23,783 per vessel annually (\$1,522,170 / 64 vessels). 2004 ex-vessel prices resulted in a greater gain for bigeye tuna gross revenues and smaller loss in BFT gross revenues (Table 4.33). The largest gain in gross revenues with 2004 ex-vessel prices would be for swordfish landings, and the greatest loss would be for yellowfin tuna (Table 4.33)

Alternative B2(d), closing all areas west of 86 degrees W. Long. to pelagic longlining in the Gulf of Mexico, would potentially impact a total of 78 vessels that fished in the area from 2001 – 2003, or an average of 65 vessels per year. A total of 12,897 sets were reported from 2001 – 2003, or an average 4,299 sets per year (Table 4.36). Without redistribution of fishing effort, alternative B2(d) would potentially result in a 47.4 percent decrease in fishing effort, and reductions in landings ranging from a minimum of 3.5 percent for bigeye tuna to a maximum of 64 percent for yellowfin tuna (Table 4.15). For yellowfin tuna, this would amount to an estimated loss of \$8,035,791 annually. The total loss for all species combined would be approximately \$10,638,133 annually (Table 4.33), or \$163,663 per vessel annually (\$10,638,133 / 65 vessels). The estimated losses using 2004 ex-vessel data were even larger than those anticipated in 2003, except for BFT (Table 4.33). The total lost gross revenue in 2004 dollars was estimated as -\$10,921,107 (Table 4.33). The closure of a major portion of the Gulf of Mexico would have the largest impact on Louisiana, where approximately 56 percent of all the vessels that reported 72 percent of all sets from the area have their homeports (Table 4.37).

With redistribution of fishing effort, alternative B2(d) is predicted to result in an overall increase in gross revenues of approximately \$6,014,934 annually, or \$92,537 per vessel, due primarily to the large potential increase in swordfish landings (62.5 percent) and bigeye tuna landings (80.6 percent) that are predicted to occur with redistribution of effort (Table 4.33). 2004 ex-vessel prices indicated largest gross revenues associated with swordfish and yellowfin tuna landings (Table 4.33). Losses associated with decreased BFT landings were less than those predicted by 2003 ex-vessel prices (-\$80,601 vs. -\$109,786; Table 4.33). As discussed earlier, these estimates do not take into account fishermen who may not relocate to open areas in the Atlantic, but may instead stay in the Gulf of Mexico where competition for existing resource may be intense, potentially resulting in fishermen going out of business.

Alternative B2(e), a 46,956 $nm^2$ closure in the Northeast, would potentially impact a total of 49 vessels that fished in the area from 2001 – 2003, or an average of 35 vessels per year. A total of 2,587 sets were reported from 2001 – 2003, or an average 862 sets per year (Table 4.36). Without redistribution of effort, total gross revenues losses would amount to approximately \$3,234,660 annually (Table 4.33), or \$92,418 per vessel annually (\$3,234,660 / 35 vessels). 2004 ex-vessel prices indicated an increase in gross losses from those anticipated with 2003 ex-vessels prices for all species without the redistribution of effort (Table 4.33). With redistribution of effort, gross revenues losses are predicted to total \$820,132 annually (Table 4.33), or \$23,432 per vessel annually ($820,132 / 35 vessels). This translated into a total gross loss of -$841,948 in 2004 (Table 4.33).

NMFS also considered combining alternatives B2(a) and B2(b), as well as alternatives B2(d) and B2(e), as described earlier under ecological impacts, to maximize bycatch reduction. Combining closures B2(a) from May through November and B2(b) in June only, resulted in the highest overall reduction in bycatch for the largest number of species under consideration. Combining these alternatives would potentially impact a total of 81 vessels that fished in the area from 2001 – 2003. A total of 3,144 sets were reported from 2001 – 2003 (Table 4.36). Without redistribution of effort, the economic impact of combining these closures would be a decrease in landings of all retained species for a loss of $5,428,120 annually (Table 4.33), or $96,930 per vessel annually ($5,428,120 / 56 vessels). This was estimated as a loss of -$5,572,508 in 2004 (Table 4.33). With redistribution of effort, the landings of all retained species are predicted to increase. The percent increase ranged from a minimum 0.3 percent for yellowfin tuna to a maximum of 10.0 percent for bigeye tuna. The result would be an increase in total gross revenues of approximately $1,091,570 annually (Table 4.33), or $19,492 per vessel annually ($1,091,570 / 56 vessels). Thus, the overall economic cost of combining alternatives B2(a) and B2(b) could potentially range from a loss of $5.42 million to a gain of $1.09 million. Using 2004 ex-vessel prices, the overall economic cost of combining the two alternatives would be a range of a loss of $5.57 million to an increase of $1.1 million (Table 4.33). Given that the actual decline in overall effort of previously enacted time/area closures was nearly twice what was predicted (Section 3.8.9; Table 4.6 and Table 4.7), the combined closures are likely to have a substantial negative economic impact. When considering the comparatively low numbers of leatherback and loggerhead sea turtle interactions, and BFT and white marlin discards that would be avoided by this closure, the economic costs appear to be high in comparison to the ecological benefits.

Combining closures B2(d) and B2(e) year-round would potentially impact a total of 127 vessels that fished in the area from 2001 – 2003. A total of 15,484 sets were reported from 2001 – 2003. Without redistribution of effort, the economic impact of combining these closures would result in a decrease in landings for a loss of $12.9 million annually (Table 4.33), or $101,633 per vessel annually ($12,907,345 / 127 vessels). In 2004, the total gross loss was estimated as -$13.25 million (Table 4.33). With redistribution of effort, the landings of swordfish and bigeye tuna are predicted to increase, whereas the remaining species are predicted to decrease. The percent increase ranged from a minimum of 63.1 percent for swordfish to a maximum of 78.4 percent for bigeye tuna (Table 4.15). The result would be an increase in total gross revenues of approximately $7,600,258 annually (Table 4.33), or $59,845 per vessel annually ($7,600,258 / 127 vessels). In 2004, the total gross revenues when the redistribution of effort considered was $7,802,425 (Table 4.33). Thus, the overall economic cost of combining alternatives B2(d) and B2(e) could potentially range from a loss of $12.9 million to a gain of $7.8 million.

In addition to any economic impacts, there could be a range of social impacts from disruption of local fishing communities to relocation of vessels and homeports as a result of any additional closures. Anecdotal information suggests that many PLL fishermen own several permits in addition to HMS limited access permits and engage in other fisheries during periods when they are not pursuing HMS. Fishermen may have had to diversify to continue to meet financial obligations and remain in business due to time/area closures; however, many changes in the HMS fisheries have been out of NMFS' control, such as increases in fuel prices and hurricanes. However, NMFS realizes that any additional economic hardship such as a time/area closure could potentially result in fishermen going out of business.

The modifications to the two closed areas, B3(a) and B3(b), would potentially result in positive social and economic impacts. Re-opening areas of either closure would allow fishermen access to previously closed fishing grounds, potentially resulting in increased landings of retained species. In addition, the modified area of B3(b) would be inshore, which would allow fishermen to have access to nearshore fishing grounds, reducing fuel costs and time at sea. However, this may create gear conflicts between recreational and commercial fishermen. Conversely, the modified area of B3(a) would be along the axis of the Gulf Stream, which would afford recreational fishermen closed portions inshore and allow PLL gear to fish in re-opened areas offshore.

Alternative B3(a), the Charleston Bump modification, would potentially result in a 0.5 percent increase in fishing effort based on 1997 – 1999 logbook data. The most prominent increase in landings would be for swordfish (1.1 percent; Table 4.27). This potential increase could result in increased revenue of $220,806 annually for swordfish alone (Table 4.34). In addition, the modification could result in increased landings of yellowfin tuna (0.16 percent; Table 4.27) and bigeye tuna (0.02 percent; Table 4.27). The total increase in potential revenues from increased landings resulting from this modification would be $234,460 annually (Table 4.34). Using 2004 ex-vessel prices, this translates into $238,417 in swordfish landings, a decrease in yellowfin tuna landings ($11,625 vs. $13,372), and approximately the same for bigeye tuna landings ($282 vs. $281; Table 4.34)

Alternative B3(b), the Northeastern U.S. modification, would potentially result in a very small increase in fishing effort (0.01 percent; Table 4.28). As with B3(a), the largest increase in landings would be for swordfish, which would translate into an increase in an annual revenue of $482 (Table 4.34). There is also a small predicted increase in yellowfin tuna landings, making the total increase in revenue associated with this modification is $550, annually (Table 4.34). 2004 ex-vessel prices predicted a slight increase for both swordfish landings ($588 vs. $482) and yellowfin tuna landings ($74 vs. $68; Table 4.34). While this is small in comparison to B3(a), this modification serves as a way for NMFS to pinpoint areas of high bycatch and refine current closed areas.

While NMFS considered each alternative individually, there is the possibility that a closure, or a combination of closures, could also be implemented in concert with a potential modification to a closed area. Since the potential modifications would most likely have positive social and economic impacts, any combination of closures with potential modifications could result in an increase in revenue. When looking at revenues associated with the potential closures after the consideration of the redistribution of fishing effort (Table 4.33), B3(a), in combination with most of the potential closed areas or combinations of potential closed areas, would result in a net increase in revenue (Table 4.33 and Table 4.34). The largest increase in annual revenue based on 2003 prices would be $7,834,718 for the B2(d)/B2(e) closure combination ($7,600,258; Table 4.33) with the B3(a) modification ($234,460; Table 4.34), or $6,249,394 for the B2(d) closure ($6,014,934; Table 4.33) and the B3(a) modification ($234,460; Table 4.34). Conversely, the greatest loss in annual revenue would be $-819,582 from the B2(e) closure (-$820,132; Table 4.33) and the B3(b) modification ($550; Table 4.34). One drawback to such combinations of closed areas and modifications would be the difficulty of compliance by the public and subsequent enforcement. Such combinations of closures and modifications during different time periods could add complex regulations for the public to adhere to and enforcement to monitor.

The preferred alternative B4 to implement complementary HMS management measures in Madison-Swanson and Steamboat Lumps Marine Reserves could potentially impact commercial and recreational fishery participants that have (1) traditionally harvested HMS from the two marine reserves, (2) provided charter or headboat trips for HMS to the areas, or (3) would be expected to harvest HMS from the two areas prior to the sunset date associated with this alternative (June 16, 2010).

As described above, from 1997 – 2003, only one PLL set and one bottom longline set were reported in the HMS logbook in these areas (Figure 4.4). No new sets were reported in 2004. Both sets occurred in the Madison-Swanson site. Four swordfish were kept on the PLL set, and eight swordfish were discarded. With regard to observer data, only one set was observed within the areas from 1994 – 2003, out of a total of 1,433 observed sets in the CSFOP during that period. No new sets were reported for the Observer Program in 2004. These data indicate that comparatively little HMS commercial fishing activity has historically occurred within these two areas, although some sandbar sharks and swordfish have been caught. Most HMS fishing activity has been reported to the west of Madison-Swanson and Steamboat Lumps.

The EA prepared by the Gulf Council estimated that the closures could affect 356 commercial fishing vessels that reported fishing in the larger Statistical Areas 6 or 8, in the snapper/grouper logbook and unknown number of for-hire vessels. The Council's closures were projected to reduce total gross revenues of commercial vessels fishing primarily in the snapper-grouper and reef fish fishery by $352,000 annually, based upon pre-closure fishing information. This was estimated to represent approximately one percent to four percent of individual gross vessel revenues if equally divided among the 356 affected vessels, or two percent to five percent of individual gross vessel revenues if 59 trap vessels (which fish in shallower waters) are excluded from the universe of affected vessels. The vast majority of the revenues derived from these areas were from landings of shallow-water groupers and other reef fish. In 2001 and 2002, coastal migratory pelagics represented only 2.1 percent of gross revenues derived from Statistical Areas 6 and 8. Based upon this information, CSFOP data, and reported sets in the HMS Logbook, NMFS does not anticipate any significant reduction in gross vessel revenues of commercial HMS vessels associated with implementing complementary HMS regulations in the Madison-Swanson and Steamboat Lumps marine reserves beyond those already projected in the Gulf Council EA (GMFMC, 2003). Because the preferred closure areas are relatively small, any HMS fishing activity that otherwise would have occurred in these areas would likely relocate to nearby open areas with similar catch rates.

The extent of HMS recreational and charter/headboat fishing activity within the marine reserves is unknown. It is, therefore, not possible to provide an estimate of the impacts of the two marine reserves on the gross revenues and profits of charter/headboat vessels. However, given the interest that this topic generated among the recreational fishing community during 2003 Gulf Council deliberations on extending the duration of the marine reserves, it may be inferred that traditionally there has been some HMS recreational fishing activity within these areas. The Gulf Council recommended that NMFS implement compatible regulations that would provide for a seasonal allowance (May – October) for surface trolling to partially alleviate any negative social or economic impacts associated with the marine reserves. Because this alternative includes the seasonal surface trolling allowance, it is not expected to substantially impact the HMS recreational or charter/headboat sector. These months coincide with a period of increased HMS recreational fishing activity in the western Gulf of Mexico. This alternative strives to balance the need to ensure adequate conservation benefits for reef species while minimizing regulatory effects on fisheries, which have limited impacts on reef species.

Preferred alternative B5 would establish criteria for regulatory framework adjustments to implement new time/area closures or make modifications to existing time/area closures. This alternative would help provide greater transparency and predictability in the decision making process and would allow fishermen to plan for future changes. Although there are no direct economic impacts resulting from the establishment of the criteria themselves, the implementation of new closures or modification of existing closures could have variable economic impacts. Positive economic impacts could result from modifications or removals of time/area closures, which would reopen areas to commercial fishing. Such modifications could allow fishermen to more readily utilize retained species, resulting in additional economic opportunity for fishermen. However, modifications to current time/area closures (*i.e.*, opening up current closures) could lead to negative social impacts if there is gear conflicts involved between recreational and commercial fishermen. Additional closures could also result in negative economic impacts in the short-term. Since the economic and social impacts related to the criteria are difficult to predict, specific economic and social impacts would be analyzed when a particular closure is contemplated.

There are expected to be minimal negative economic or social impacts due to alternative B6, the closure off the southwest tip of Key West to bottom longline gear to protect smalltooth sawfish. However, calculating the economic and social impact of this closure is more difficult than calculating the impacts of closures for PLL gear; impacts for this closure are based on the CSFOP, which only covers approximately 1.6 percent of the commercial shark bottom longline vessels (based on the number of hooks set). Commercial shark bottom longline vessels typically report their landings in the snapper/grouper logbook, however, these landings are reported according to statistical reporting areas, and not according to locations of individual sets as is reported in the HMS logbook. Therefore, NMFS must extrapolate the number of sets that may have occurred from 2001 – 2003 in the B6 closure from the 1994 – 2006 CSFOP.

Since this closure is small in size, it is expected to affect very few bottom longline fishermen. For instance, 18 sets of the total 1,563 sets observed by the CSFOP from 1994 – 2006 occurred in the potential closed area. The level of observer coverage has ranged from approximately 1.6 percent (based on the number of hooks set) to four percent (based on LCS landings) of the HMS-permitted bottom longline vessels. Using a mid-range value of observer coverage (2.8 percent), it is estimated that approximately 55,821 HMS commercial bottom longline sets (1,563 sets / 2.8 percent observer coverage) occurred during this time, with 642 sets occurring in the closure area (18 sets / 2.8 percent observer coverage). Since bottom longline vessels in the Gulf of Mexico soak their gear an average of 11.25 hr/set (Burgess and Morgan, 2003), NMFS estimates that each vessel would have made one set per day. Thus, the closed area could affect 1.2 percent (642 sets / 55,821 sets) of the sets based on the number of sets between 1994 – 2006 or approximately 49 fishing days a year for the entire HMS bottom longline fleet (*i.e.*, 642 sets / 13 years ~ 49 sets per year). Given the extrapolated nature of these estimates, NMFS cannot estimate the economic impact of this closure in 2003 or 2004 dollars nor can NMFS determine which state would be most impacted by such a closure.

In addition, the closed area would help reduce the number of interactions with smalltooth sawfish by the bottom longline fishing industry, thereby helping the bottom longline industry stay below their Incidental Take Statement (ITS) for smalltooth sawfish (which is 260 interactions over five years with no reported fishing mortalities). Staying below the ITS will have positive economic and social impacts by keeping the entire bottom longline fishery open and operating, allowing economic gain by the bottom longline fishermen and their associated communities.

Alternative B7, which would prohibit pelagic longlining in all areas, would potentially impact a total of 177 active vessels that made 30,409 sets from 2001 – 2003 (Table 4.36). Active vessels are defined as vessels that reported landings in the HMS logbook during the years in question. It would have immediate and significant economic and social impacts on the longline vessel owners, vessel operators, and crew that would need to re-rig their vessels to continue fishing for HMS, find alternative fisheries, or discontinue fishing. It would also negatively impact dealers that purchase fish from PLL vessels, and families who own the fishing vessels that would either have to re-rig or discontinue fishing. It would also indirectly impact the local communities that support the PLL fishery. Figures 9.4 and 9.7 show the spatial distribution of tuna and swordfish permit holders, and Tables 9.36 and 9.39 show the number of tuna or swordfish permit holders per state. The states with the most tuna permit holders are Massachusetts (31.5 percent), North Carolina (12.9 percent), Maine (10.2 percent), New Jersey (7.0 percent), and New York (6.4 percent) (Table 9.36). The states with the most swordfish permit holders are Florida (32.4 percent), New Jersey (13.9 percent), Louisiana (11.9 percent), Massachusetts (9.1 percent), and New York (8.0 percent) (Table 9.39). In 2004, the total fishery revenue was $21.4 million for tunas (compared to $49.9 million in 2003) and $15.4 million for swordfish (compared to $14.6 million in 2003; Table 3.65 in Section 3.5.1.2). In 2004, the PLL fishery accounted for annual gross revenues of $14.9 million for swordfish, $871,187 for BFT, $9.1 million for yellowfin tuna, and $1.6 million for bigeye tuna based on average ex-vessel prices ($/lb dw) for 2004 (Table 4.32 and Table 3.65 in Section 3.5.1.2). Thus, closing the PLL fishery would result in, at a minimum, a loss of $26.5 million in revenue. However, this does not include revenue lost from sharks and other tunas and finfish landings. In addition, this estimate does not take into account the negative indirect economic and social impacts that small local businesses and fishing communities, which support the PLL industry, will also experience from such an industry closure.

In addition, under ATCA, the United States cannot implement measures that have the effect of raising or lowering quota, although NMFS has the ability to change the allocation of that quota among different gear groups. The swordfish fishery is confined, by regulation, to three gear types: harpoon, longline, and handlines. Since it is unlikely that the handgear sector would be able to catch the quota given the size distribution of the stock, prohibiting longline gear may reduce the ability of U.S. fishermen to harvest the full quota. It would also have the effect of reducing traditional participation in the swordfish fishery by U.S. vessels relative to the foreign competitors because the United States would harvest a vastly reduced proportion of the overall quota.

Summary of Alternatives

After carefully reviewing the results of all the different time/area closures analyses, including different scenarios of redistributed effort, NMFS is preferring not to implement any new closures, except the complementary measures in the Madison-Swanson and Steamboat Lumps Marine Reserves, and not to modify any existing closures at this time. Alternatives B4 and B5 are the preferred alternatives. Alternative B4 would establish complementary HMS regulations in the Madison-Swanson and Steamboat Lumps Marine Reserves at the request of the GMFMC with minimal ecological, economic, or social impacts. Alternative B5 would establish criteria that would guide future decision-making regarding implementation or modification of time/area closures. This alternative was a preferred alternative because it would provide enhanced transparency, predictability, and understanding of HMS management decisions, allow for more adaptive management, and should result in minimal social and economic impacts. Any impacts for specific closures would be analyzed when those closures are considered.

At this time, the following alternatives are not preferred for a variety of reasons. The ecological benefits of alternatives B2(a) through B2(e) for white marlin, BFT, and sea turtles are predicted to be variable with redistribution of effort, with potential negative ecological impacts to several species. All closures had predicted reductions in bycatch and discards without consideration of redistributed effort. For instance, B2(d) predicted some of the largest decreases in spearfish bycatch (83.5 percent), leatherback turtle interactions (57.5 percent) and yellowfin tuna discards (66.4 percent). However, no redistribution of effort assumes that all fishing effort that occurred in the closed area would cease if a closure was implemented and would not be transferred elsewhere. Therefore, a closure such as B2(d) was also predicted to have large negative economic impacts with a predicted 53.6 percent and 64 percent reduction in retained bluefin and yellowfin tuna, respectively. Under redistribution of effort assumptions, each of these alternatives (B2(a) through B2(e)) was predicted to result in an increase in bycatch of at least one, and in several cases, more than one of the species considered (Table 4.5 and Table A.37 through Table A.42 in Appendix A). For example, alternative B2(a) (May-November), intended primarily to reduce leatherback sea turtle interactions, and white marlin and BFT discards, could result in a 7.9 percent increase in loggerhead sea turtle interactions and a 10.3 percent increase in BFT discards (Table 4.5). Even the modified redistribution of effort model for alternative B2(a) predicted increases in sailfish discards (4.7 percent; Table A.37 in Appendix A), LCS discards (4.4 percent; Table A.37 in Appendix A), BFT discards (1.6 percent; Table A.38 in Appendix A), and BAYS discards (0.7 percent; Table A.38 in Appendix A). When closure areas were combined, the redistribution of effort model predicted similar results with an increase in discards of several species. For example, combining alternatives B2(a) (May – Nov) with B2(b) (June only) would result in a 1.5 percent increase in sailfish, 9.6 percent increase in pelagic sharks, and 10.1 percent increase in LCS discards (Table 4.21). Combining alternatives B2(d) with B2(e) (year-round) would result in a 6.5 percent increase in white marlin, a 12.1 percent increase in spearfish discards, and a 4.8 percent increase in loggerhead sea turtle interactions (Table 4.23).

Alternatives B3(a) and B3(b) were considered to refine existing closures and to provide additional opportunity to harvest legal-sized swordfish while not increasing bycatch. Additional swordfish catch is desirable because the United States has not lately met its quota under ICCAT. As of April 30, 2006, only 18 percent of the directed North Atlantic swordfish quota and 2 percent of the incidental North Atlantic swordfish quota had been filed, leaving 4,905.9 mt and 294.7 mt of directed and incidental quota, respectively, still available for the 2005 fishing year. NMFS, however, is not preferring any modifications to the existing closures. None of the modifications considered would have resulted in a large enough increase in retained catch to alleviate concerns over uncaught portions of the swordfish and BFT quotas. For instance, B3(a) was predicted to increase retained swordfish catch by only 30.72 mt, and B3(a) was predicted to increase the retained swordfish catch by 0.07 mt. In addition, modifications to existing closures could result in increased bycatch of blue and white marlin, which is a concern given the stock status of blue and white marlin and the scheduled white marlin ESA review. Increased interactions with sea turtles and marine mammals (*e.g.*, pilot whales and Risso's dolphins) are an additional concern.

Finally, all of the analyses (those analyzing the impacts of new closures and those analyzing the impacts of modifications to existing closures) were conducted using J-hook data. New circle hook management measures were put into place in 2004, and NMFS is still assessing the effects of circle hooks on bycatch rates for HMS. Until NMFS can better evaluate the effects of circle hooks on bycatch reduction, especially with regard to sea turtles interactions and bycatch of other non-target HMS, NMFS prefers, at this time, not to modify the current time/area closures. NMFS intends to reconsider modifications to existing closures once further analyses of circle hook data are available as well as the results of stock assessments for blue marlin, white marlin, north and south swordfish, eastern and western BFT, and LCS when they become available. Given the general anticipation that the North Atlantic swordfish stock will be identified as fully rebuilt, per the pending September 2006 stock assessment, a number of fishermen and others have asked NMFS to assist in revitalizing this fishery. One option that has been raised is opening the time/area closures. While NMFS does not prefer modifying any existing closures at this time, under the preferred alternative, NMFS could modify the closed areas and/or allow experiments to test gears or other fishing methods in the closed areas. Similarly, pending the results of the marlin and BFT stock assessments, the criteria could allow for additional closures to be considered for all HMS fisheries.

Alternative B6, to prohibit bottom longline gear in an area southwest of Key West to protect endangered smalltooth sawfish, is not preferred due to the low number of observed interactions of smalltooth sawfish with BLL gear, the highly variable and episodic nature of interactions with smalltooth sawfish, and the fact that almost all of the smalltooth sawfish observed caught on BLL gear were released alive (one was released in unknown condition). Only one smalltooth sawfish has been observed in the shark gillnet fishery, and it was also released alive. There is also a lack of current information on smalltooth sawfish critical habitat. Once critical habitat has been designated by the SSRT, NMFS may consider a closure in areas where bottom longline or other HMS gears overlap with critical habitat. Until the SSRT and NMFS can coordinate on appropriate areas to close for smalltooth sawfish, NMFS feels it is premature to implement a closure for smalltooth sawfish at this time.

Finally, while alternative B7 (close all areas to PLL gear in HMS fisheries) would result in the greatest short-term ecological benefits of all the alternatives, it would also have severe economic impacts on permit holders in multiple communities and states ranging from Maine to Texas. As described above under social/economic consequences, in recent years there have been 177 active PLL vessels with annual gross fishery revenues in excess of $25 million in 2003. This revenue was ~27 million in 2004. Therefore, this alternative would have a significant impact on communities, individuals, and small businesses. Additionally, fishing mortality of several species of concern (*i.e.*, marlin, BFT, and sea turtles) may increase if the Unites States' quota is reallocated to other ICCAT countries that do not have comparable conservation bycatch reduction methods. NMFS does not prefer eliminating the entire PLL fishery at this time because of the significant economic impacts, the potential effect of shifting quota to other countries, and the likely increase in fishing mortality of both HMS and protected species. NMFS is addressing bycatch and bycatch mortality in other sections of this FMP (Chapters 6, 7, 8, and 9 and other sections within Chapter 4 such as workshops and Atlantic billfish).

<u>Overall Conclusion</u>

NMFS used POP and HMS logbook data to identify new areas for time/area closures and selected alternatives based on these data to further analyze 10 different closures or modifications for this rulemaking. NMFS also considered new time/area closures based on a settlement agreement relating to white marlin, which was approved by the court in <u>Center for Biological Diversity v. NMFS</u>, Civ. Action No. 04-0063 (D.D.C.), and a petition for rulemaking received by the Blue Ocean Institute. NMFS chose to use absolute numbers of discards and bycatch instead of CPUEs to identify areas for closures as well as for the time/area analyses in order to maximize the reduction in the overall number of discards (for further discussion, please see page 4-28). In addition, NMFS used HMS logbook data to analyze redistribution of effort. While NMFS is aware that discards may be underreported in the HMS logbook, the HMS logbook data were collected over the entire PLL fleet and provided an effort estimate for the entire fleet, which is needed for redistribution calculations, whereas POP data are only collected from a portion of the fleet (for further discussion, please see pages 4-32 to 4-33). NMFS also calculated the ecological, social, and economic impacts of each closure with and without the consideration of redistributed effort.

NMFS evaluated the reduction in discards of white marlin, blue marlin, sailfish, spearfish, leatherback sea turtles, loggerhead sea turtles, other sea turtles, and BFT without redistribution of effort based on POP data (Table 4.4) and the HMS logbook data (Table 4.5 and Table 4.15) for the various time/area closure alternatives. In addition, individual tables for each of the alternatives are presented to show the monthly discards or landings of non-target or target HMS respectively, that include pelagic and large coastal sharks, and the percent reduction in numbers of hooks set based on HMS logbook data. A time series of HMS logbook data are also presented for the estimated change in targeted and retained catch of swordfish, bluefin, bigeye, albacore, yellowfin, and skipjack tunas (BAYS) for each closure (please see Table 4.6 and Table 4.19).

NMFS evaluated different scenarios for redistribution of fishing effort, where each scenario had different assumptions regarding how fishing effort would be redistributed into open areas. The model used in this time/area analysis was the same model used in previous time/area rulemakings that resulted in implementation of closed areas (for more information on redistribution of effort model selection, please see page 4-30). Additional redistribution scenarios were considered based on comments received on the Draft Consolidated HMS FMP and the OMB reviews. Considering redistribution of fishing effort is important because fishermen are unlikely to stop fishing as a result of a closure, and are more likely to move to open areas to continue fishing. Thus it is important to take into account any additional effort in open areas that may result in an increase in bycatch. In addition, HMS and protected species are not uniformly distributed throughout the ocean, and tend to occur in higher concentrations in certain areas. Therefore, a closure in one area might reduce the bycatch of one or two species, but may increase bycatch of others as fishing effort in those areas increases.

The scenario(s) used for each closure depend on the spatial size and temporal duration of the individual closure. One scenario assumed that fishing effort (*i.e.*, hooks) from a closed area would be displaced into all remaining open areas. In this case, effort from a closed area was multiplied by the average CPUE for each species from all the remaining open areas (for further discussion, refer to Appendix A and Table A.28). NMFS also considered scenarios that assumed all fishing effort would only be redistributed within a) the Gulf of Mexico only, b) the Gulf of Mexico and the eastern seaboard, and c) the Gulf of Mexico and other areas of the Atlantic. The last scenario assumed that fishing effort would be displaced within the Gulf of Mexico and into another area where the majority of vessels with Gulf of Mexico homeports have reported fishing during 2001 – 2004 (*i.e.*, Area 6). In each of these scenarios, the effort from a closure was multiplied by the CPUE for each species either for the Gulf of Mexico only or for only the eastern seaboard, or by the CPUE for the Gulf of Mexico and Area 6 (for further discussion, please refer to pages 4-32 and 4-33, Appendix A, and Tables A.29 and A.30). These different scenarios were developed after NMFS evaluated the movement of the PLL fleet based on 2001 – 2004 HMS logbook data, which indicated where the fleet has been fishing in the Atlantic, Caribbean, and Gulf of Mexico (for further discussion, please refer to pages 4-32 and 4-33).

Each scenario of the redistribution of effort model had different assumptions. For instance, the scenario where effort from a closed area was redistributed to all open areas assumed that all fishing effort in a closed area would be distributed to open areas in the Gulf of Mexico and the Atlantic (*e.g.*, fishermen will move out of the closed area but continue fishing in surrounding open areas, move their business, or sell their permits to someone near an open area). This scenario also assumed fishermen could fish far away from their homeports, and fishermen have the ability to leave their communities, unloading docks, and other associated infrastructure to fish in the remaining open areas. Other scenarios assumed the movement of fishermen was confined to areas near their homeports assumed that fishermen do not relocate, possibly due to community ties to unloading docks, processing plants, etc. These additional scenarios also assumed that the same amount of effort would be moved out of a given area regardless of the size of the closure implemented. In reality, larger closures may result in more movement in order for fishermen to find open areas to fish and stay in business.

Predicting fishermen's behavior is difficult, especially as some factors that may determine whether to stay in the fishery, relocate, or leave the fishery are beyond NMFS' control (fuel prices, infrastructure, hurricanes, etc.). While some fishermen will continue to fish in the remaining open areas of the Atlantic, Caribbean, and Gulf of Mexico, others may be forced to leave the fishery entirely, such as selling their permits and going out of business, as a result of the closure. In addition, given the limited access restrictions of permits for other fisheries, NMFS predicts that it would be difficult for fishermen to switch to a different gear and different fisheries unless they currently possess other permits. NMFS has looked at the effect of the current closures on a fishery-wide basis (please see the analysis of alternative B1 on pages 4-33 through 4-35). This analysis indicated that there was an overall 15 percent decline in fishing effort between 1997-1999 and 2001 – 2003 or since the existing closures went into place (Table 4.8). However, there was also a reported increase in fishing effort of about eight percent in the Gulf of Mexico during this time period (Table 4.8), suggesting some shift in effort, possibly due to the existing closures. At this time, NMFS cannot precisely predict how individual vessels would move in response to a closure. For the purpose of this analysis, NMFS believes it is reasonable to assume that some redistribution of effort will occur even though NMFS cannot predict how much or where. However, in the future, NMFS intends to investigate the choices fishermen have made regarding previous closures (*i.e.*, did they move, sell their permits, go out of business, retain their permit but fish for something else, etc?). This type of analysis could help NMFS improve the effort redistribution models used in the future.

NMFS' decision to not prefer any new closures, except the complementary measures in the Madison-Swanson and Steamboat Lumps Marine Reserves, and not to modify any existing closures at this time is based primarily upon the analyses described in this section indicating that no single closure or combination of closures would reduce the bycatch of all species considered, assuming there is some redistribution of effort (Table 4.5 and Table 4.15 and Tables A.37 through A.42). NMFS decision assumes that there will be some redistribution of effort if a new closure is implemented. While NMFS recognizes that the analysis of the change in effort and bycatch after implementation of existing closures indicates that reduction in bycatch may have been greater than predicted with redistribution of effort (Table 4.6 and Table 4.7), and in some cases, without redistribution of effort, there was also an increase in fishing effort in the open areas in the Gulf of Mexico after the implementation of the existing closures (Table 4.8), which suggests that fishing effort will be displaced to other areas. In addition, the existing closures were the first round of closures implemented for HMS. The reported reduction in bycatch and discards as a result of these initial closures may not be seen in the future from additional closures, especially given the reduced size of the PLL fleet since 1997 – 1999. Based on the results of these analyses and considering that some level of displaced effort will occur, NMFS does not feel it is appropriate to implement additional closures or modify existing closures at this time. Furthermore, while the Magnuson-Stevens Act provides NMFS the authority to manage all species, NMFS must balance the impacts of management measures on all managed species and may not choose protections for one species to the detriment of protected and overfished species (*e.g.*, NMFS may not choose to protect BFT even if sea turtle interactions or bycatch of overfished species may increase substantially). For instance, even with the additional scenarios of redistributed effort for B2(c), there is a predicted increase for LCS discards (12.8 percent or 2,545 over 3 ½ years), blue marlin discards (0.7 percent or 20 over 3 ½ years), sailfish discards (21.7 percent or 281 over 3 ½ years), and spearfish discards (2 percent or 10 over 3 ½ years)

(Table A.41). Given either the overfished stock status or unknown stock status of these species, NMFS does not prefer to implement a new closure, such as B2(c), at this time. National Standard 1, which requires NMFS to prevent overfishing while achieving on a continuing basis, the optimum yield from each fishery for the United States fishing industry, applies to all species and all fisheries. Similarly, National Standard 9, which requires NMFS to minimize bycatch and bycatch mortality to the extent practicable, applies to all species and fisheries. Furthermore, the economic impacts of each of the alternatives may be substantial, ranging in losses of up to several million dollars annually, depending upon the alternative, and displacement of a significant number of fishing vessels (Table 4.33 and Table 4.35). Thus, NMFS feels that the impact on all species must be considered and any negative impacts must be minimized.

Future Efforts

With regard to the Gulf of Mexico, although NMFS has decided to not move forward with B2(c), or any other closure in the Gulf of Mexico at this time, NMFS will be pursuing alternatives to reduce bycatch in the Gulf of Mexico, especially for BFT. NMFS has currently adopted all of the ICCAT recommendations regarding BFT, a rebuilding plan is in place domestically for this species, and NMFS has implemented measures to rebuild this overfished stock. NMFS is currently trying to assess how protecting one age class at the potential detriment of other age classes will affect the fish stock as a whole. For instance, how will protecting spawning BFT help rebuild the stock if it results in increased discards of non-spawning adults, juveniles, and sub-adult BFT along the eastern seaboard? Therefore, more information is needed to further understand how to manage this species given its complex migratory patterns, life history, and age structure. NMFS is also considering developing incentives that would dissuade fishermen from keeping incidentally caught BFT, particularly spawning BFT, in the Gulf of Mexico. This may involve research on how changes in fishing practices may help reduce bycatch of non-target species as well as the tracking of discards (dead and alive) by all gear types. In addition, sea surface temperatures in the Gulf of Mexico have recently been thought to be associated with congregations of BFT and putative BFT spawning grounds in the Gulf of Mexico (Block, pers. comm.). NMFS intends to investigate the variability associated with sea surface temperatures as well as the temporal and spatial consistency of the association of BFT with these temperatures regimes. By better understanding what influences the distribution and timing of BFT in the Gulf of Mexico, NMFS can work on developing tailored management measures over space and time to maximize ecological benefits while minimizing economic impacts to the extent practicable.

In addition, NMFS prefers not to implement new closures or modify existing closures because all of the data used in the time/area analyses were based on J-hook data. New circle hook management measures were put into place in 2004, and NMFS is still assessing the effects of circle hooks on bycatch rates for HMS. Until NMFS can better evaluate the effects of circle hooks on bycatch reduction, especially with regard to sea turtles interactions and bycatch of other non-target HMS, NMFS prefers not to implement new or modify the current time/area closures at this time. While time/area closures play an important part in resource management, a number of time/area closures have been implemented since 2000. Those closures are beginning to demonstrate their conservation benefits (for further discussion of the effect of current closures, refer to pages 4-33 through 4-35); however, NMFS is still trying to assess the effect of additional management measures, such as circle hooks, that have been implemented since 2000. NMFS currently only has finalized data on the catch associated with circle hooks from July through December of 2004 (see Appendix A). Based on the NED experiment, circle hooks likely have a significantly different catch rate than J-hooks. Therefore, further investigations are required to determine the potential impact of any new time/area closures as well as assess the cumulative affect of current time/area closures and circle hooks. NMFS anticipates that 2005 HMS logbook final data will become available in the summer of 2006 when the quality control procedures on the 2005 HMS logbook data are complete.

NMFS is also awaiting additional information regarding the status of the PLL fleet after the devastating hurricanes in the Gulf of Mexico during the fall of 2005. A majority of the PLL fleet was thought to be severely damaged or destroyed during the 2005 hurricane season. The amount of PLL fishing effort, especially within the Gulf of Mexico, will be assessed in the summer of 2006 when 2005 HMS logbook final data becomes available. Until NMFS can better estimate the current fishing effort and potential recovery of the PLL fleet, NMFS believes it is premature to implement any new time/area closures at the present time. Additionally, a number of stock assessments will be conducted during 2006 (LCS, blue marlin, white marlin, North and South Atlantic swordfish, and eastern and western Atlantic BFT). NMFS is awaiting the results of these stock assessments to help determine domestic measures with regard to management of these species, especially for North Atlantic swordfish, white marlin and western Atlantic BFT.

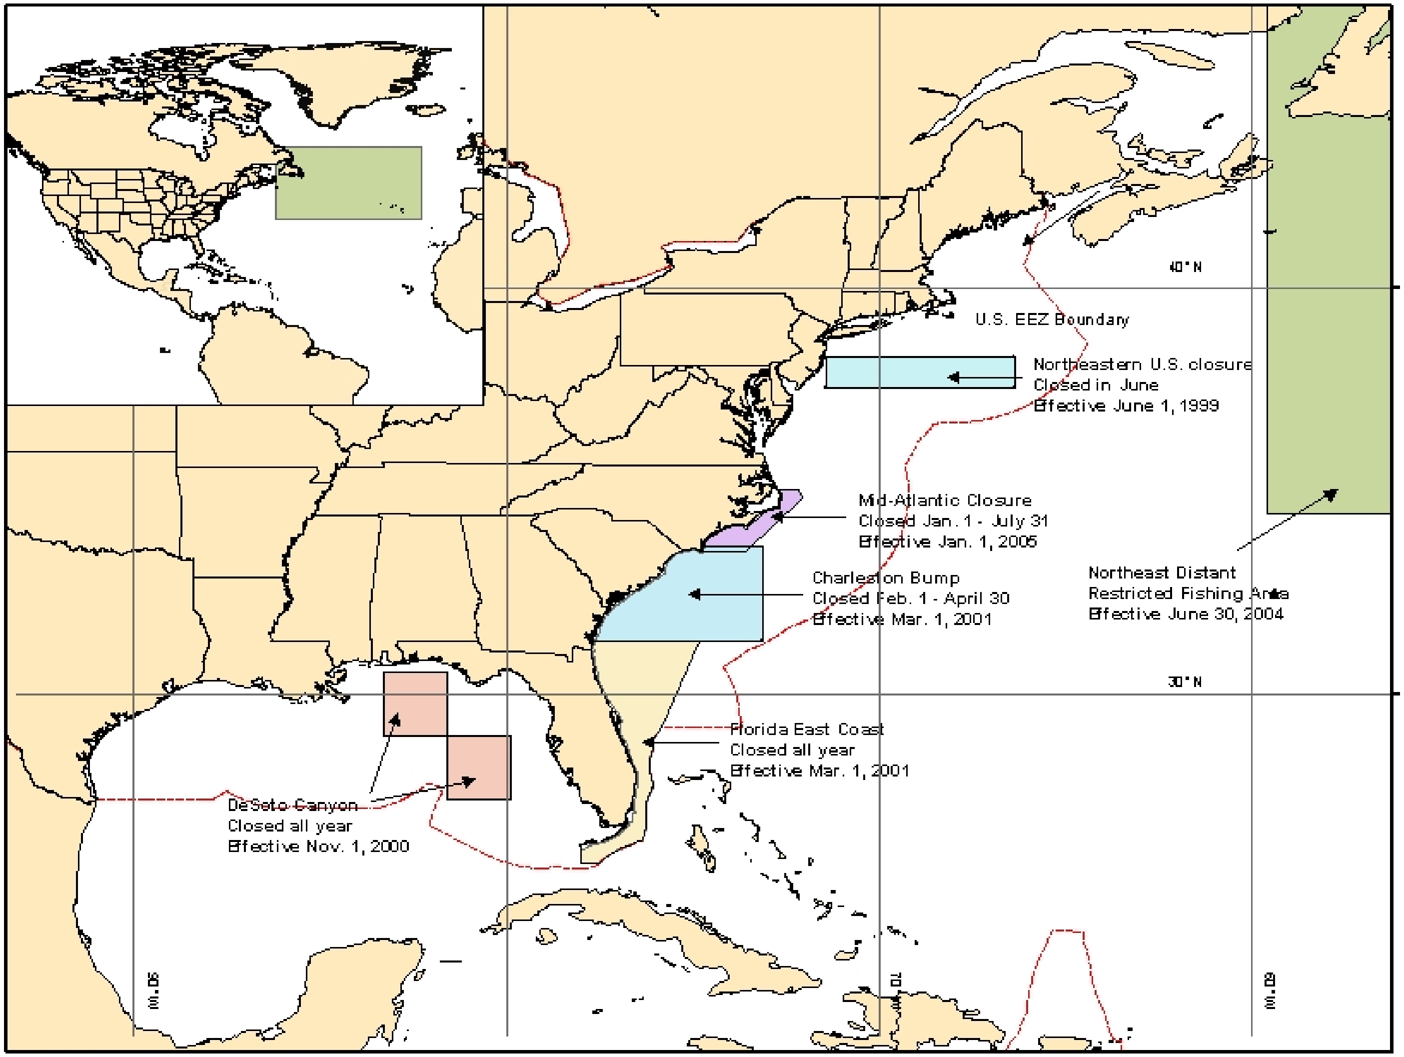

**Figure 4.1** **Existing time/area closures in HMS fisheries. Inset shows extent of the Northeast Distant restricted fishing area. All closures except the Mid-Atlantic are applicable to PLL gear only. The Mid-Atlantic Closure is applicable to bottom longline gear only. Note: the Northeast Distant (NED) was a closed area to all vessels as of 2001. It became the NED Restricted Fishing Area on June 30, 2004 when it was opened to those participating in the NED experiment.**

## 4.2 Rebuilding and Preventing Overfishing

### 4.2.1 Northern Albacore Tuna

ICCAT assumes three Atlantic albacore stocks for assessment purposes: northern and southern Atlantic stocks, separated at 5° N latitude, and a Mediterranean stock (See Section 3.2.3.3). ICCAT's SCRS conducted a stock assessment for the northern stock in 2000, using data from 1975 through 1999. Based on the results of this stock assessment, at its November 2000 meeting, ICCAT recommended a total allowable catch (TAC) of 34,500 mt ww with an allocation to the United States of 607 mt ww. Subsequent ICCAT recommendations have extended both the 34,500 mt ww TAC, and the U.S. share of 607 mt ww, through 2006.

In 2004, SCRS advice was based on the 2000 assessment as updated with CPUE trends through 2003. SCRS concluded that the northern stock is probably about 30 percent below $B_{MSY}$, but the possibility of a lower $B_{MSY}$ could not be dismissed. It was further concluded that northern albacore was not being growth overfished[1] and that spawning stock biomass could be increased if catches do not exceed 31,000 mt (ww) (SCRS, 2004). SCRS plans to conduct the next stock assessment in 2007. ICCAT does not currently have a rebuilding plan for this species.

U.S. harvest of Atlantic Northern albacore tuna has historically been less than two percent of the recorded total international landings, based on 1997 through 2004 data. Approximately 98 percent of total U.S. landings are harvested primarily by rod and reel and pelagic longline fisheries in the Northwest Atlantic (See Table 3.60). Since the 2000 ICCAT recommendation of a 607 mt TAC was implemented, U.S. fishing year landings have been well below the annual TAC of 607 mt (ww) until 2004. In 2004, U.S. calendar year landings of 645.9 mt remained 16 percent below the adjusted annual quota of 765.2 mt. The United States had a domestic adjusted quota in the 2005 fishing year of 728.8 metric tons.

As described in Chapter 2, the alternatives considered for a rebuilding plan are:

C1 Maintain compliance with the current ICCAT recommendation (No Action)

C2 Unilateral proportional reduction of United States northern albacore fishing mortality

C3 *Establish the foundation with ICCAT for developing an international rebuilding program – Preferred Alternative*

*Ecological Impacts*

The SCRS has determined that, under the current exploitation limits, the total catch has remained below the 34,500 metric ton TAC for 2001-2003, although they have not been able to assess the effect of this limit on the stock. However in 2004, a northern albacore tuna stock

[1] Growth overfishing occurs when animals are harvested at an average size that is smaller than the size required to produce the maximum yield per recruit. The total yield from the fishery is therefore less than it would be if the fishing mortality rate was lower. In such a case, less fishing would produce higher landings. This is true even when the resource is abundant. Stock depletion and stock collapse are caused by recruitment overfishing. This means that the adult population was fished so heavily that the number and size of the adult population (spawning biomass) was reduced to the point that it did not have the reproductive capacity to replenish itself.

update using CPUE trends through 2003 indicated the stock was probably about 30 percent below MSY.

Alternative C1, the No Action alternative, would not be expected to result in any ecological impacts, as no changes in the stock status, bycatch, or catch rates are expected. This alternative would not establish a foundation to develop an international rebuilding plan for overfished northern albacore tuna and would be inconsistent with Magnuson-Stevens Act, which requires rebuilding plans for overfished stocks.

Alternative C2, which would implement unilateral U.S. restrictions in albacore landings, would not be expected to result in any changes in the stock status. The U.S. harvest is so low relative to the international 34,500 mt TAC that any positive ecological impacts resulting from decreased albacore landings would be expected to be negligible. NMFS received comment supporting unilateral action and the implementation of bag limits and seasonal limits on albacore landings. It is likely that a unilateral rebuilding plan would require reductions in landings from both the commercial and recreational sectors. Such an action could potentially change fishing behavior and/or increase dead discards because albacore are an incidental catch when directing for other species. NMFS also received a comment opposing unilateral action because such restrictions would only create unnecessary waste and discards, and that such actions would weaken the U.S. negotiating position at ICCAT. The agency agrees that implementation of an ineffective unilateral rebuilding plan may weaken the U.S. negotiation position at ICCAT to implement an effective international rebuilding plan, potentially resulting in continued international fishing on a stock biomass below MSY. Furthermore, setting the U.S. quota above or below current ICCAT recommendations would not be consistent with Magnuson-Stevens Act §304(g) (1) (d) and ATCA.

Alternative C3, a preferred alternative to establish a foundation for an international rebuilding plan, would have no immediate ecological impacts, as ICCAT would probably develop an international rebuilding plan following the next scheduled stock assessment in 2007. This alternative would allow for international discussions and the creation of a comprehensive rebuilding plan for all three Atlantic stocks of albacore. Following implementation of rebuilding plan recommendation(s), some negative impacts would be possible as changes in fishing practices may be necessary to reduce fishing mortality, which may result in an increase in dead discards in U.S. fisheries due to quotas, size limits, or other restrictions. However, engaging all concerned ICCAT parties in the rebuilding would be expected to generate long term positive ecological impacts. As the stock rebuilds and more resource becomes available to the fleet, U.S. quotas would likely increase and dead discards may decline.

Under the preferred alternative C3, the United States would work through ICCAT to establish a foundation for an international rebuilding program for northern albacore tuna. Implementation of this alternative would include a thorough analysis of the ICCAT Rebuilding Program to ensure that it contains a specified recovery period, biomass targets, fishing mortality rate limits, and explicit interim milestones expressed in terms of measurable improvements of the stock. Each of these components would comply with the objectives of this FMP and the intent of the Magnuson-Stevens Act. If successful, an Atlantic-wide TAC for northern albacore tuna, along with other conservation and management measures, would be adopted by ICCAT to rebuild the stock. The United States would then implement the ICCAT Rebuilding Program for northern albacore tuna through appropriate management measures such as quotas and/or increased minimum sizes and retention limits in domestic fisheries. Such a rebuilding plan would be expected to reduce harvest levels, which could increase discards of northern albacore tuna because the pelagic longline fishery primarily targets other species. Fishermen may increase fishing effort to compensate for lost revenues from northern albacore that would have to be discarded. Therefore, reduction in landings of northern albacore tuna could also cause a shift in both commercial and recreational fishing effort, and perhaps mortality, towards other species. Overall, however, alternative C3 would likely result in long term positive ecological impacts on the stock because current international catch rates exceed the levels needed to produce MSY.

*Social and Economic Impacts*

There would essentially be no impact from alternative C1, the No Action alternative, as the U.S. fleets are currently fishing below their ICCAT allocation. For commercial fisheries, alternative C2, implementation of a unilateral rebuilding plan, would likely result in a reduction in income, as incidental catches of northern albacore tuna would have to be discarded rather than landed. However, expected reductions in income would be small since the level of landings for northern albacore is two orders of magnitude smaller than pelagic longline target species (e.g., swordfish, other tunas). For the recreational fishery, alternative C2 would likely result in shifts for other opportunistic target species and catch and release of northern albacore tuna. Economic impacts would be difficult to evaluate for the recreational fishery since there is high variation in the catch from year to year. As ICCAT has not yet adopted a rebuilding program for northern albacore tuna, a complete analysis of the social and economic impacts of alternative C3 cannot be conducted at this time. If the ICCAT Rebuilding Program involves a substantial reduction in allowable catch, minimum size restrictions, or effort restrictions, there would likely be a short-term reduction in economic benefits to the pelagic longline fishery until the stock recovers. Since northern albacore tuna are targeted by recreational fishermen in certain times of the year and in certain areas, it is difficult to estimate the effect that a reduction in allowable landings of northern albacore would have on angler consumer surplus. It might be reduced, but to an unknown extent, because many recreational trips targeting northern albacore tuna often target other tuna species. Overall, however, ICCAT recommendations for stock rebuilding tend to be long term and so any negative social and economic impacts may be mitigated in the short term.

*Conclusion*

The preferred alternative for northern albacore tuna is C3, which would establish a foundation with ICCAT for developing an international rebuilding plan. This alternative appears to be an effective plan for meeting the objectives of the Magnuson-Stevens Act, ATCA, and this FMP. NMFS will continue to work with ICCAT member nations to develop and adopt an appropriate international rebuilding plan for northern albacore tuna with a specified recovery period, biomass targets, fishing mortality rate limits, and explicit interim milestones. The U.S. harvest of the North Atlantic stock is proportionally so low that the socio-economic impacts to the United States would likely be minimal but would depend upon the specifics of the rebuilding plan adopted by ICCAT. The other alternatives of no action or unilateral action would not be consistent with the Magnuson-Stevens Act or ATCA. Also, alternative C2 would not be consistent with Magnuson-Stevens Act §304(g)(1)(d) and ATCA because it would set the U.S.

quota above or below the current ICCAT recommendation. Furthermore, implementation of an ineffective unilateral rebuilding plan may weaken the U.S. negotiation position at ICCAT to implement an international rebuilding plan, potentially resulting in continued international fishing on a stock biomass below MSY.

### 4.2.2 Finetooth Sharks

NMFS determined that overfishing of finetooth sharks is occurring based on the 2002 stock assessment for SCS (Cortes, 2002). More detailed information on the stock assessment can be found in the Status of the Stocks section (Section 3.2.5) of this document. National Standard 1 of the Magnuson-Stevens Act requires NMFS to prevent overfishing. As described in Chapter 2, the alternatives considered to address overfishing of finetooth sharks are:

D1 Maintain current regulations for recreational and commercial fisheries. (No Action),

D2 Implement commercial management measures to reduce fishing mortality of finetooth sharks,

D3 Implement recreational management measures to reduce fishing mortality of finetooth sharks, and

*D4 Identify sources of finetooth fishing mortality to target appropriate management actions. (Preferred Alternative).*

*Ecological Impacts*

None of the alternatives analyzed for preventing overfishing of finetooth sharks would have any additional negative impacts on protected resources or EFH. The alternatives considered are not expected to modify fishing techniques, fishing effort, or fishing gears in any way that has not already been considered in relevant BiOp's. Furthermore, the measures are not expected to have "more than minimal and not temporary" impacts on areas that have designated as EFH for finetooth sharks.

Alternative D1 is the No Action alternative and would maintain the existing regulations. This alternative would likely maintain fishing mortality of finetooth sharks at current levels, and therefore, may have negative ecological impacts. Over 80 percent of finetooth sharks harvested commercially are landed with either drift gillnets, strikenets, encircling nets, or sinknets. Finetooth sharks are susceptible to these net gears as they have a tendency to "roll" upon contact with gillnets. This rolling behavior means that they become entangled by a wide range of gillnet mesh sizes and are often brought to the vessel dead (Carlson and Cortes, 2003). Currently, commercial gillnets are banned in most states' waters throughout the finetooth sharks' range, including: Georgia, Florida, Texas, and Louisiana. South Carolina allows the use of gillnets less than 100' long (30.4 m) in state waters. South Carolina's gillnet fishery is primarily a recreational fishery. Between 1997 and 2003, 95 and 99 percent of the finetooth landings reported to the General Canvass and Coastal Fisheries logbooks, respectively, were from the South Atlantic region (Table 4.40). Finetooth sharks are generally found in shallow coastal waters (Castro, 1993) in predominantly state, but also in Federal waters. For more information on finetooth shark life history, please see Section 3.2.5.

The ecological impacts of the alternatives are difficult to quantify because it is difficult to determine exactly which fisheries are contributing to commercial and recreational landings of finetooth sharks because Federal dealer logbooks (General Canvass) are not linked to a specific vessel; rather, they are an aggregation of shark purchases from various fishermen and submitted every 14 days. Recreational landings of finetooth sharks in state and Federal waters do not have to be reported, therefore, it is difficult to quantify these landings. Vessel logbooks submitted by shark and other Federal permit holders indicate which vessels are landing finetooth sharks, however, these landings only represent a fraction of the total dealer landings (General Canvas landings) for finetooth sharks (Table 4.40 and Table 4.41). This discrepancy may be a result of landings in state waters by non-Federally permitted fishermen, landings by Federally permitted fishermen who are not reporting all their catch in logbooks, misidentification of finetooth sharks by the dealers, or landings of finetooth sharks by vessels that are targeting unmanaged species and therefore are not required to report landings in logbooks.

Based on observer reports, the directed shark fishery landed an average of 685 finetooth sharks (approximately 2.9 mt dw) per year between 1999 and 2004 (Table 4.41). The range of annual landings varied widely from 65 to 1,615 individual finetooth sharks per year. The average number of finetooth observed landed per year equates to approximately 3.6 percent of the average number of finetooth landings reported by dealers to the General Canvass system during the same time period (1999-2004). There are several reasons why there is a discrepancy between observed landings and landings reported by dealers. One reason could be because historically there were more directed (*i.e.*, Federally permitted) shark gillnet vessels (11) subject to observer coverage. Overtime, the number of gillnet vessels specifically targeting sharks has decreased. Currently, there are between 5 and 6 vessels targeting sharks with gillnet gear that are subject to extensive observer coverage. However, there are other vessels that use gillnet gear, target other species, and land sharks. In 2003, there were approximately 15 gillnet vessels with directed shark permits that reported landing finetooth sharks. These vessels also possessed permits for, and targeted, Spanish mackerel. Because these vessels were not specifically targeting sharks, observer coverage may not have been required if fishermen claimed they were targeting non-HMS (Spanish mackerel or unmanaged species) or not using shark gillnet gear. These vessels may be using gillnets that have stretched mesh smaller than 5 inches. Under the regulations for the Atlantic Large Whale Take Reduction Plan (ALWTRP), gillnets with stretched mess smaller than 5 inches are not considered shark gillnet vessels. Thus, while these vessels are able to land finetooth sharks opportunistically under their directed shark permit, they were not previously observed as part of the shark gillnet fishery.

In 2005, NMFS modified the criteria for selection of gillnet vessels for observer coverage requirement outside of the right whale calving season (Nov. 15 – March 31) when 100 percent coverage in the Southeast U.S. Restricted Area is required. New criteria outside of the calving season included all vessels with a directed shark permit that reported fishing for sharks with gillnet gear and reported greater than 25 percent of their total landings from sharks during the previous year. This modification does not include those vessels selected for 100 percent observer coverage based on the ALWTRP. The 100 percent observer coverage under that plan only includes vessels that have stretched mesh gillnets five inches or greater. While observer coverage is extensive during the right whale calving season (100 percent from November 15 –

March 31), it does not include all of the vessels that can land sharks with gillnet gear. Additionally, observer coverage outside the Atlantic Right whale calving season (April 1 – November 14) is reduced to approximately 30 percent. Figure 4.18 indicates that the majority of trips landing finetooth occur between October and March every year. Increasing the pool of vessels that are subject to observer coverage has led, and would continue to lead, to improved understanding of finetooth shark landings outside of the current 5-6 boats that comprise the directed shark gillnet fishery universe.

As described in Section 3.4. and in the 2005 Directed Shark Gillnet Fishery Observer Program Report, the gear and soak time deployed by drift gillnet, strike gillnet, and sink gillnet fishermen are varied. Set duration was generally 0.3 hours and haulback averaged 2.9 hours. The average time from setting the net through completion of haulback was 10.2 hours. The most frequently used mesh size for drift gillnets was 12.7 cm. Strikenetters use the largest mesh size (22.9 cm) and the set times were 2.7 hours. The primary difference between sink gillnets and other gillnets (drift gillnets and strikenets) is the species being targeted. Sink gillnets can be used to target sharks, Spanish mackerel, and kingfish. These sink gillnets are generally weighted with a lead line in 10-20 m (33-65 ft.) of water, with the net being checked every 15-20 minutes. Sink gillnet gear is fished slightly differently depending the target species (sharks vs. non-sharks). If targeting Spanish mackerel or southern kingfish, vessels deploy a 68-912 m long net that is 1-9 m deep. Mesh sizes range from 6.4-12.7 cm with 7.6 cm being the most common. Vessels targeting sharks deployed sink gillnets between 137 and 1,824 m in length and 2-8 m deep with mesh sizes ranging from 7.3-20.3 cm (17.8 cm most common) and set at an average depth of 18.9 m (Carlson and Bethea, 2006). The No Action alternative would not affect or modify any of the gillnet gear that currently being deployed for finetooth sharks, other HMS and non-HMS species.

The No Action alternative (D1) may not result in the acquisition of additional landings data or information about fisheries that may be landing finetooth sharks. By taking no action, the Agency may not be able to obtain the additional information on fisheries that may be harvesting finetooth sharks. This could prevent the Agency from identifying further management measures to prevent overfishing of finetooth sharks, and may reduce the certainty associated with the stock status of finetooth sharks and other SCS in the upcoming stock assessment. Furthermore, the No Action alternative would not result in the development of collaborative efforts between management entities, which may be the most effective means of preventing overfishing of finetooth sharks.

While the No Action alternative is not expected to have positive ecological benefits, NMFS recently published a temporary rule under the authority of the ALWTRP and the Endangered Species Act (February, 16, 2006, 71 FR 8223) that prohibited, through March 31, 2006, any vessel from fishing with any gillnet gear in the Atlantic Ocean between 32º N and 27º 51' N and extended the Southeast U.S. Restricted Area out to 80º W. This action was based on NMFS' determination that a right whale mortality, documented on January 22, 2006, was the result of an entanglement by gillnet gear within the Southeast U.S. Restricted Area. The action was necessary to protect north Atlantic right whales from further serious injury or mortality from entanglement in gillnet gear. Because this six-week gillnet closure occurred at a time when finetooth sharks are generally present in the Southeast U.S. Restricted Area, it is expected that the closure would result in positive ecological impacts for finetooth sharks. The actual impact will likely not be known until dealer and logbook data are analyzed. In addition to this temporary rule, the Atlantic Large Whale Take Reduction Team (ALWTRT) is likely to initiate further rulemaking prior to re-opening the Southeast U.S. Restricted Area next year during this six-week time period (Feb. 14 – March 31) to address this take. NMFS would expect that any recommendations that reduce the use of gillnet gear during that time period would have positive ecological benefits for fineooth sharks. The actual benefit is not quantifiable at this time.

Alternative D2 would implement commercial fishery management measures (directed trip limits for SCS, gillnet gear restrictions, prohibiting the use of gillnet gear for targeting sharks, and/or reducing the SCS quota) to reduce fishing mortality of finetooth sharks. As described above, the majority of finetooth sharks are landed by commercial fishermen deploying gillnet gear in the South Atlantic region. This alternative might potentially affect all participants in possession of a commercial shark permit who are involved in gillnet fisheries in the south Atlantic or Gulf of Mexico regions.

A directed shark gillnet vessel is defined as a vessel that possesses directed shark permits and fishes with gillnets greater than 5 inch (12.7 cm) stretched mesh. These vessels are prohibited from deploying shark drift gillnet gear in the Southeast U.S. Restricted Area (roughly between Sebastian Inlet, FL, and Savannah, GA) during the right whale calving season between November 15 and March 31, unless they are fishing with strikenets and maintain 100 percent observer coverage. Also, during right whale calving season, directed shark gillnet vessels fishing outside the restricted area are subject to 100 percent observer coverage. Any vessel that has been issued a directed shark permit and that has gillnet gear onboard, regardless of location or mesh size, must have an operating VMS unit onboard during right whale calving season.

Currently, there are five directed shark gillnet vessels targeting sharks with drift gillnets, strikenets, and sinknets in Federal waters. These five gillnet vessels are responsible for less than 10 percent of the commercial finetooth shark landings based on observer reports (Table 4.41). The remaining finetooth sharks are likely being landed in state waters or by fishermen pursuing other species in Federal waters, such as those managed by the Gulf of Mexico or South Atlantic Fishery Management Councils (*e.g.*, Spanish and king mackerel) or species that are not currently managed (*e.g.*, kingfish). Since some of these fishermen may also possess directed shark permits, they can keep all finetooth sharks. However, because their harvest of finetooth sharks is incidental to landing of other non-HMS species or they are deploying gillnet gear with stretched mesh sizes less than five inches, these vessels are not subject to the stringent regulations implemented for the Southeastern U.S. Restricted Area, which are only applicable for vessels targeting sharks using shark gillnets (>5" stretched mesh) or strikenets. Vessels in the directed shark gillnet fishery also possess other permits and may modify gillnets to target other non-HMS. Thus, the measures under alternative D2 may have positive ecological impacts in general, but because they would not impact fishermen who do not *target* finetooth sharks, may not have an impact on the commercial fisheries that are the largest source(s) of finetooth shark fishing mortality. In fact, it is likely that some of the measures under alternative D2 would increase dead discards of finetooth sharks by preventing fishermen targeting other fish from landing finetooth sharks, thereby increasing the effort they expend in order to land enough permissible species to cover fishing costs.

One of the management measures considered under alternative D2 is a trip limit for directed shark permit holders. Currently, there is no directed trip limit for SCS. A directed trip limit for SCS or one specific to finetooth sharks could potentially reduce the number of finetooth sharks landed per trip. However, since the overall SCS quota has never been taken in any single year, fishermen would likely compensate for missed income as a result of the trip limit by increasing the number of trips taken and discarding any sharks fish harvested in excess of the trip limit. Given that gillnets are the predominant gear type used to harvest finetooth sharks and finetooth sharks tend to roll and die in gillnets, this alternative may result in an increased number of finetooth sharks dying by increasing the number of finetooth sharks that are discarded dead, by increasing the number of gillnet trips by vessels to maintain economic viability, or both. Additionally, gillnet gear is generally non-selective, and it is difficult for fishermen to deploy sets that would not also catch finetooth sharks. Thus, the net effect of this measure may increase, rather than prevent, overfishing on finetooth sharks which would result in negative ecological impacts.

Other management measures possible under alternative D2 are gear restrictions, specifically those that would modify mesh size and/or limit gillnet soak times. Soak times and mesh sizes deployed in this fishery are described above and in Section 3.4. Currently, for directed shark fisheries, the 50 CFR Part 635 regulations do not define a minimum or maximum mesh size requirement. Vessels targeting king and Spanish mackerel already have minimum mesh size restrictions of 4.75 and 3.5 inches (12.1 and 8.9 cm), respectively. The ALWTRP regulations define shark gillnet as having a minimum of 5 inches mesh size. For many species, limiting the mesh size is effective at reducing interactions because the fish swim through the net (the mesh is too big), are "gilled" by the net (if the mesh size is appropriate for that fish), or the fish swims into the net and swims away (the mesh size is too small). However, as noted under alternative D1, finetooth sharks are highly susceptible to entanglement in gillnet gear regardless of mesh size. Thus regulating the mesh size used in directed shark fisheries may have little impact on reducing finetooth shark fishing mortality. Similarly, while limiting the soak time (*i.e.*, the time the gillnet gear is in the water) may reduce the number of finetooth sharks harvested per trip as well as the catch of other SCS and LCS, fishermen may simply increase the number of sets made per trip to compensate for reduced catches which could potentially negate any benefit gained by reduced soak times. Thus, NMFS does not believe that modifying gillnet mesh size and/or limiting gillnet soak times would reduce finetooth shark fishing mortality or result in any significant ecological benefits.

Another management measure possible under alternative D2 would be a reduction in the overall SCS quota. Since it was established in 1999, the SCS annual quota has not been caught and finetooth sharks are the only species in the SCS complex that are experiencing overfishing. Between 1999 and 2002**,** total commercial landings of all SCS ranged from 263-330 mt dw per year. This was well below the 1,760 mt dw quotas established for SCS during this time period. In 2003, the quota was reduced to 326 mt dw, a reduction of 1,434 mt dw. The current quota of 454 mt dw was established in 2004. From 1999 – 2004, commercial landings of finetooth sharks averaged 34 percent of the SCS landings (Table 4.41). Given that the existing quota for SCS has never been reached and that finetooth sharks represent approximately a third of the SCS that are landed, a reduction in the overall quota may have minimal beneficial impacts on reducing the mortality of finetooth sharks. Furthermore, even if the quota were reduced, it may not necessarily mean that landings of finetooth sharks would decrease because the quota includes all SCS.

Lastly, under alternative D2, NMFS could close the shark gillnet fishery and remove gillnet gear from the list of authorized gears. The Agency received numerous comments during this rulemaking, including one from the State of Georgia, indicating support for closing the directed shark gillnet fishery. A similar alternative was analyzed in Amendment 1 to the Fishery Management Plan for Atlantic Tunas, Swordfish, and Sharks. As was determined at that time, banning gillnets in HMS fisheries would likely have positive ecological impacts on finetooth sharks and other species (including HMS and non-HMS species) by reducing bycatch and bycatch mortality, and may reduce gillnet fishing effort in areas that are designated as right whale critical habitat. However, because very few vessels use drift gillnets, strikenets, and sinknets to target sharks and may only be responsible for a small portion of the finetooth shark fishing mortality, closing this fishery would not likely prevent overfishing because other vessels would continue to land (or discard dead) finetooth sharks while targeting other non-HMS. Most of the directed shark gillnet vessels also possess Spanish mackerel permits and would continue deploying gillnet gear in that fishery. Regarding gillnet fishing effort in the Southeastern U.S. restricted area, unauthorized gillnets would continue to be deployed in this area in other fisheries and the potential for interactions with right whales would continue to exist despite removal of gillnet gear from the authorized gear for sharks. Moreover, a permanent closure of the shark gillnet fishery may displace fishing effort to other fisheries, resulting in unknown ecological impacts. Vessels may shift to BLL gear, which is the primary gear used to target LCS but also can be used to harvest finetooth sharks. Therefore, these species might be subject to additional fishing pressure from the vessels that used to fish primarily with gillnet gear.

NMFS also received a comment indicating support for initiating a cap on the number of vessels that can use gillnet gear to target sharks. NMFS does not currently issue gear-based permits for shark fisheries. Rather, permit holders possess either directed or incidental permits and both permits are valid for use with any authorized gear for sharks (gillnet, bottom and pelagic longlines, handline, rod and reel, or bandit gear). Additionally, logbook and permit data does not indicate that there has not been a significant increase in recent years in the number of vessels targeting sharks with gillnet gear. The majority of shark fishermen employ bottom longline gear. NMFS did not consider gear based permitting endorsements in this rulemaking but may consider gear-based permits in another rulemaking (see Chapter 1). Such a rulemaking could consider limiting vessel participation in the shark gillnet fishery.

The Agency received several comments in support of seasonal commercial gillnet fishing restrictions to reduce finetooth shark fishing mortality, including one from the South Atlantic Fishery Management Council. Seasonal closures of commercial gillnet fisheries landing finetooth shark were not analyzed as part of alternative D2, however, these closures may be considered in the future, as necessary, to reduce fishing mortality of finetooth sharks. Trips that landed finetooth sharks, by gear and month, between 1999 - 2004 were analyzed from the Coastal Fisheries Logbook data. This data indicates that there is an increase in the number of trips landing finetooth sharks in October and November. This could be due to finetooth sharks moving southward from the Carolinas to warmer waters off of Florida in these months. Furthermore, the expansion of effort targeting Spanish mackerel as they are also moving south to Florida in October and November each year might also be a factor behind elevated finetooth shark landings. Finetooth sharks tend to move in schools north and south along the coast, depending on water temperatures and forage availability. Initiating annual geographic closures based on these paramaters would be confounding as oceanographic conditions are difficult to predict. Furthermore, initiating seasonal closures based on logbook data indicating where finetooth sharks have historically been landed (Table 4.44 and Figure 4.18) may not reduce fishing mortality because gillnet gear would likely continue to be deployed in these same areas for fisheries that are pursuing other species (*i.e.*, Spanish mackerel)**.** Since most of the fishing pressure on finetooth sharks occurs on finetooth sharks after they have pupped in the coastal waters (2-7 m ( water depth) surrounding Bulls Bay, SC in May it is difficult to use protection during pupping as a justification for seasonal closures as most states in the region have already banned gillnet gear for commercial fisheries. Seasonal commercial gillnet fishing restrictions were not considered in this rulemaking but may result in positive ecological impacts and may be considered in a future rulemaking. These closures would have to be for all gillnets as fishermen are not able to exclude finetooth sharks from being caught in this gear.

Alternative D3 would implement recreational management measures (*e.g*., mandatory use of circle hooks and/or increasing the minimum size) to reduce fishing mortality of finetooth sharks. The current Federal minimum size is already approximately 15-20 cm (six to eight inches) greater than the size at maturity. Some states have smaller minimum size requirements, more liberal bag limits, and do not require compliance with Federal regulations when fishing in state waters. Babcock and Pikitch (2002) claim that the majority of sharks (LCS, SCS, and Pelagic sharks) sampled by the MRFSS survey were below the existing minimum size limits. Ecological impacts of increasing the minimum size would be contingent upon compliance with existing and or future regulations. Since finetooth sharks are predominantly found in inshore waters under states' jurisdiction, where additional Federal regulations traditionally may have limited impact, the positive ecological impacts of increasing the minimum size further might be minimized.

A preferred measure (alternative I11 (b)) included in this action would require all recreational anglers with an HMS Angling, CHB, or General Category permit to abide by Federal regulations regardless of where they are fishing, unless a particular state has more stringent regulations. This measure could have positive ecological impacts because it would compel recreational fishermen to abide by the more stringent Federal minimum sizes and bag limits for recreational shark harvest. If more stringent Federal measures, regardless of where one were fishing, were implemented as a result of alternative I11 (b), improved consistency between Federal and state regulations might occur as a result. Improved compliance with existing and future regulations is necessary to prevent overfishing of finetooth sharks. Similar analyses related to increasing the minimum size were conducted in Amendment 1 to the 1999 HMS FMP. Additional consideration of increasing the minimum size has produced no new information/data on which to base a change in the current minimum size because most landings of finetooth sharks are likely in state waters, finetooth sharks only comprise a small portion of recreational SCS landings (1.4 percent), and the minimum size is already well above the size at first maturity for finetooth sharks. The results from the next SCS stock assessment should be available in 2007 and further information regarding the status of finetooth shark stocks may warrant reconsideration of this alternative at that time.

Although NMFS received several comments supporting more aggressive conservation measures to protect finetooth sharks in recreational fisheries, measures affecting the minimum size in Federal waters may have negligible ecological impacts since recreational fisheries are already regulated under a conservative bag limit and minimum size well under size at first maturity. Furthermore, since finetooth sharks only comprised 1.4 percent of recreational SCS landings between 1999 and 2004, it does not seem that there are many participants targeting finetooth sharks.

Another management measure under alternative D3 is a requirement to use circle hooks when targeting SCS in the recreational fishery. Currently, there are no other recreational HMS fisheries that have a circle hook requirement. However, a preferred alternative in this action (alternative E3) would restrict all billfish tournament participants issued an HMS permit to using circle hooks when using natural baits. Requiring circle hooks when targeting SCS may have some ecological benefits by reducing the post-release mortality of finetooth sharks, assuming that similar decreases in post-release mortality may be achieved for finetooth sharks as for other HMS that have been studied. Cooke and Suski (2004) suggest that overall post-release mortality rates are often lower when using circle hooks compared to J-hooks because of the reduced likelihood of fish ingesting the hook. However, they also recommend that management agencies implement circle hook requirements only in instances in which appropriate scientific data for similar species exists. While there have been numerous studies evaluating ecological benefits of circle hook usage in recreational fisheries, including several HMS, these studies have not been conducted in recreational fisheries that specifically target sharks to demonstrate decreases in post- release mortality compared to J-hooks for these fishes. In general, sharks caught in recreational fisheries are thought to have low post-release mortalities if they are kept in the water, handled properly, not deeply hooked, and not fought for extensive periods of time because many species of sharks are considered relatively hardy based on tag recaptures. Gurshin and Szedlmayer (2004) recently documented high post-release survival (nine out of ten hooked fish) of Atlantic sharpnose sharks on 9/0 J-hooks. The absence of similar research on circle hooks, coupled with reports of low post-release mortality for similar species caught with J-hooks, precludes a quantitative estimate of the ecological benefits to finetooth sharks that may occur as a result of requiring circle hooks.

Alternative D4, the preferred alternative, is expected to result in positive long-term ecological impacts. This alternative, while it does not prevent overfishing immediately, would implement a plan to prevent overfishing of finetooth sharks, through determining which fisheries catch finetooth sharks, and to what extent, those fisheries are responsible for mortality of finetooth sharks. NMFS believes that the measures contained in alternative D4 comprise an appropriate plan to implement at this time for the following reasons: information regarding finetooth shark landings is currently incomplete; landings or dead discards of finetooth sharks would continue to occur or could increase in other fisheries if stringent measures directed at commercial shark permit holders were implemented; the lack of catch series and bycatch data included in the 2002 SCS stock assessment (Section 3.2.5) impacted the results and conclusions drawn from that assessment; and that collaborative management measures among fisheries management entities may be the most effective means of preventing overfishing of finetooth sharks. A better understanding of where finetooth sharks are being landed, by whom, and which management entities are responsible for the fisheries in which they participate, could direct future management initiatives.

Table 2.1 lists activities, anticipated outcomes, and a timeline that constitute the plan to prevent overfishing of finetooth sharks as a result of alternative D4. This table and the actions it describes were produced in response to public and HMS Advisory Panel dissatisfaction related to the activities that had been undertaken to prevent overfishing of finetooth sharks and serves as a road map detailing how the Agency is engaged in current and future activities related to this end. Some of the activities described have already been initiated to attain a better understanding of how NMFS should proceed to prevent overfishing of finetooth sharks. The activities described in this table are not an exhaustive list and the Agency intends to explore other viable alternatives that would prevent overfishing if necessary. NMFS received several comments stating that the Agency needs to work harder to find sources of finetooth shark mortality in state-managed, Federally managed, and/or unmanaged fisheries. The following paragraphs provide a summary of NMFS' findings since the publication of the Draft Consolidated HMS FMP. In order to attempt to understand which fisheries may be interacting with finetooth sharks it is necessary to understand which permits (if any) that vessels maintain; what other species were being landed simultaneously or on the same trip as finetooth sharks based on Federal logbook data; the seasonality and geography of finetooth shark landings; and, to establish contacts with individual states, Councils, and Commissions to get more information on fisheries nder their jurisdiction that may be interacting with finetooth sharks, among other activities. Acquiring this information could focus future management initiatives which may result in positive ecological impacts if they can be employed to prevent further overfishing of finetooth sharks.

A recent analysis of landings data submitted via the Fishing Vessel Logbook Record for Gulf of Mexico Reef Fish, South Atlantic Snapper-Grouper, King and Spanish Mackerel, and Shark (Coastal Fisheries Logbook) between 1999-2004 indicate that a total of 46 vessels reported landings of finetooth sharks. Of these, 17 vessels only had a shark limited access permit, 17 vessels had both a directed shark permit and a Spanish mackerel permit (managed under the Coastal Pelagics FMP and its amendments by the South Atlantic Fishery Management Council), and 12 vessels had neither permit. In 2003, 15 vessels reported landings of finetooth sharks, all of which had both a shark directed permit and a Spanish mackerel permit. Management measures for shark fishing under commercial Federal shark permits would effectively only address finetooth shark fishing mortality by the 34 (17 vessels with a shark permit only + 17 vessels with a shark permit in addition to a Spanish mackerel permit) vessels that have a shark limited access permit. Preventing overfishing of finetooth sharks will be facilitated by understanding what permits that participants currently possess because that provides insight as to what regulations might be most effective at modifying current practices. Since the South Atlantic Fishery Management Council manages Spanish mackerel under the Coastal Pelagics FMP, and many participants possess this permit, the Agency is engaging in collaborative efforts with the South Atlantic Fishery Management Council, and may propose specific management measures in the future as new information warrants. Collaborative management measures may be the most viable option to ensure sustained long-term positive ecological impacts and prevent overfising of finetooth sharks.

Observed finetooth shark landings in 2005 included 1,556 finetooth sharks landed by strike gillnet gear, 413 finetooth sharks landed by drift gillnet gear, and 37 finetooth sharks landed by sink gillnet gear. On trips deploying sinknet gear and not targeting sharks, southern kingfish and Spanish mackerel were the most commonly encountered species. However, these trips interacted with 13 finetooth sharks, all of which were landed. The average size of finetooth sharks landed in 2005 was 123 cm, based on measurements attained from 38 individuals (Carlson and Bethea, 2006). As mentioned previously, many of the Federally managed gillnet vessels in the South Atlantic that were observed possess both Spanish mackerel and directed or incidental shark permits, thereby limiting the effectiveness of regulations directed at only one of these fisheries, and suggesting the need for collaborative strategies between management entities.

Expansion of this program was initiated in 2005 and will continue in the future, yielding valuable fisheries dependent data on finetooth shark landings, distribution, and interactions with vessels outside of the vessels traditionally covered by this observer program resulting in positive ecological impacts. Furthermore, data from observers on protected species interactions and other bycatch has utility for fisheries managers, scientists, and law enforcement officials. Vessels strictly targeting unmanaged species (and not in possession of a directed shark permit) such as kingfish are not subject to observer coverage under the regulations at 50 CFR Part 635 and are not required to submit logbooks, but may still be harvesting finetooth sharks. These vessels could be selected for observer coverage under the ALWTRP regulations which could further enhance efforts to document landings of finetooth sharks in non-HMS or unregulated fisheries, resulting in positive ecological impacts. The ALWTRP is currently engaged in efforts to better address gillnet vessels that are participating in unmanaged fisheries in the Southeast U.S. Restricted Area.

The Agency has been actively involved in gathering more information about fisheries that may be interacting with finetooth sharks, especially off the coast of Florida where most finetooth sharks are landed. NMFS collected some anecdotal information describing gillnet fisheries for Spanish mackerel and kingfish at a recent meeting of the Atlantic Large Whale Take Reduction Team in St. Augustine, FL, April 10-12, 2006, to better understand the fisheries that may be harvesting finetooth sharks. The intent of this meeting was to determine if additional management measures may be necessary to further regulate gillnet fisheries in the Southeast U.S. Restricted Area because of the right whale calf mortality that occurred on January 22, 2006. The fisheries information that was gathered is critical to understanding the potential for interactions with finetooth sharks in fisheries where finetooth sharks are not being targeted. The Spanish mackerel gillnet fishery deploys gillnets that are a minimum of 3.5 inch stretched mesh and the fishery occurs predominantly between September and December, until the water temperature drops below 69ºF. Fishermen fish one net at a time, at one hour intervals, and the soak ends when the nets are hauled onboard. Buoys are marked with permit numbers every 100 yards, and fishermen are allowed to possess two, 800 yard nets, per vessel. These participants may also target Spanish mackerel at night (fire fishing) when conditions are such that phosphorescence in the water is activated by schools of Spanish mackerel. Gillnet sets for Spanish mackerel that also harvest sharks, including finetooth sharks, are not uncommon. Spanish mackerel fishermen report their harvests in the same logbooks that shark fishermen use to report their landings (Coastal Fisheries Logbook). The Agency will be participating in the Spanish mackerel species working group at an upcoming South Atlantic Fishery Management council meeting in June, 2006, to gain additional information about this fishery and to determine how future collaborative regulations might address finetooth shark fishing mortality, resulting in positive ecological impacts.

NMFS also obtained anecdotal information on the kingfish (whiting) fishery that is occurring off the northeast coast of Florida at the St. Augustine meeting of the ALWTRT. The Agency learned about this fishery from staff at the Southeast Fisheries Science Center and from HMS fishermen in 2004, however, the meeting in St. Augustine provided additional substantive information about how the fishery is conducted, gear deployed, set duration, etc. This fishery started in 2004 and includes approximately 15 vessels, three of which possess directed shark permits. This fishery deploys sinknets in 60-70 feet of water (in Federal waters) as the kingfish prefer cooler water temperatures. Fishing methods are essentially the same for most vessels, however, there is some variation in how nets are retrieved. Soak times vary; however, nets are generally set at dawn for 4-6 hours. Gear may be left overnight and retrieved the next morning. Fishermen may deploy 2-3 nets at a time. The majority of gillnets are less than 3 inch stretched mesh, approximately 1.22 m (4 feet) high, with variable gillnet lengths. Since only three of these vessels possess directed shark permits, NMFS does not have complete information on landings of finetooth sharks in this fishery. Vessels participating in this fishery can't be selected for observer coverage under HMS regulations if they do not possess a limited access HMS permit. Participants in this fishery do not currently need to possess Federal permits for kingfish, therefore, there is no requirement for them to report any of their landings in logbooks. Gillnets deployed for kingfish are in areas that finetooth sharks likely inhabit, however, these fishermen would not be able to possess or land sharks legally without a limited access shark permit. Including the kingfish fishery within some type of management regime would result in positive ecological impacts for finetooth sharks and other species of incidental catch or bycatch that this fishery may be interacting with. The Agency will continue to stay engaged in the deliberations of the ALWTRT and any potential management measures they may implement to regulate gillnet fishing in the Southeast U.S. Restricted Area and minimize interactions between gillnet gear and right whales.

NMFS has learned more about other fisheries that may be landing finetooth sharks by analyzing the Coastal Fisheries Logbook data which describes the non-HMS species that were landed with finetooth sharks by Federally permitted vessels between 1999 - 2004 (Table 4.42 and Table 4.43). These data indicate that the majority of finetooth sharks are landed with gillnet gear (81 percent) or bottom longline gear (19 percent). Trips landing finetooth sharks generally included 21.5 and 8.3 percent non-HMS, in gillnet and bottom longline trips, respectively. Non-HMS species landed on gillnet trips included (in descending order): Spanish mackerel (13.6 percent), bluefish (2.73 percent), blue runner (1.51 percent), little tunny (0.59 percent), king whiting (kingfish) (0.42 percent), and cobia (0.32 percent). These data may be somewhat misleading, however, since they indicate the percent of total landings by *weight*, on trips that also landed finetooth sharks. Generally speaking, the HMS listed in these tables may have a greater whole weight on average than the non-HMS species and may not be representative of the number of individuals (HMS or non-HMS) landed. Furthermore, the Coastal Fisheries Logbook is a trip report (versus a set report) that fishermen complete upon returning to port and therefore does not provide set-specific information that would indicate whether or not fishermen are able to "target" HMS or non-HMS on individual sets, or simply opportunistically land whatever species they are permitted to keep. Understanding the catch composition of trips that are landing finetooth sharks may assist the Agency in determining potential management measures that prevent overfishing of finetooth sharks and reduce incidental or non-target catch. NMFS has, and will continue to place observers on vessels targeting non-HMS and in possession of a commercial shark permit to get more information on this fishery via the DSGFOP. Since gillnets are generally a non-selective gear, it is important to understand other species that fishermen may be landing when they harvest finetooth sharks so that potential future regulations are not circumvented by participants claiming they are targeting species other than finetooth sharks (or other HMS).

Coastal Fisheries Logbook data also indicated the geographic location of where the majority of finetooth sharks were landed between 1999 and 2004. Gillnets are banned, or restricted in many states' waters in the southeast region and the majority of finetooth shark landings are reported in Statistical Reporting areas immediately adjacent to Florida and South Carolina's state waters. Table 4.44 describes the number of trips landing finetooth sharks by NMFS statistical reporting area. A map of the statistical reporting areas is also provided (Figure 4.18). The majority of the trips landing finetooth sharks take place off Florida and South Carolina where gillnet gear is banned or limited to 100' total length, respectively.

Finetooth shark trips by gear and month for the years 1999 - 2004 (total) from the Coastal Fisheries Logbook are provided in Figure 4.18. This figure depicts the seasonality of when finetooth sharks are being landed with various gear types. It is interesting to note that the finetooth sharks landings with gillnet gear seem to spike in the month of November. This could be attributed to finetooth sharks moving southward from the Carolinas to warmer waters off of Florida (Castro, 1993) leading to an increase in finetooth shark abundance at this time. Spanish mackerel also generally move south to Florida in October –November each year. During the months of April through November, the trip limit for Spanish mackerel is 3,500 lbs/vessel/trip, whereas between December and March, it is unlimited in Florida's Atlantic EEZ. The fact that finetooth shark and Spanish mackerel fisheries may be spatially and/or temporally linked reiterates the importance of collaborative management measures to address overfishing of finetooth sharks because finetooth sharks may still be landed by gillnet vessels participating in other fisheries, despite measures implemented for commercial shark fishing.

NMFS contacted individual states between Texas and North Carolina (the presumed range of finetooth sharks) and created a table describing applicable fisheries regulations, whether or not the state allows gillnets to be deployed in state waters, commercial fisheries that may landing finetooth sharks, and the species code for finetooth sharks (if applicable) (Table 4.45). Contacts were also made with states responsible for monitoring of trip ticket or general dealer data to determine whether there were finetooth sharks being landed and reported in state waters that may not be included in General Canvass (Federal) dealer reports. Some of these state landings data are more comprehensive in that they can be traced to an individual vessel's identification number. NMFS is also awaiting additional trip ticket landings data from other states who participate in the Gulf of Mexico's Fisheries Identification Network (FIN) program, administered by the Gulf States Marine Fisheries Commission, which will provide more detailed landings information for finetooth sharks by state. While NMFS does not have jurisdiction over state waters, understanding the extent to which state fisheries may be interacting with finetooth sharks, and how these landings are accounted for, is essential to foster collaborative relationships between the Federal government and individual states to prevent overfishing of finetooth sharks. The Agency is interested in having finetooth sharks included in any fisheries observer programs operating in state waters to attain additional catch series data for stock assessments and explore collaborative management strategies. Attaining more data on state landings of finetooth sharks and inclusion of finetooth sharks for bycatch sampling in observer programs in state waters would result in additional landings data; in turn, resulting in positive ecological impacts.

Table 4.46 describes landings data from Florida's Trip Ticket program which include all dealers with a state Saltwater Products License. These landings would include all finetooth sharks landed and sold in the state of Florida between 1999 - 2004 and would include landings in state waters and/or landings that were not offloaded by a Federally permitted vessel or to a Federally permitted dealer. The advantage of these landings data compared to the General Canvass data submitted by Federally permitted shark dealers is that they include landings in state waters by vessels that may not have a Federal permit and, since 2000, provide the vessel ID of the vessel that reported landing the fish.

The Florida Trip Ticket landings include a higher proportion of finetooth sharks being landed in gillnet gears (92.8 percent) compared to the Coastal Fisheries Logbook (81 percent). Furthermore, they also indicate that finetooth sharks are being landed by several types of gillnet (runaround, generic, drift) starting in 2003. The majority of the landings occur within Federal waters (EEZ), however, 44,142 lbs dw (20 mt dw) of finetooth shark were listed as being landed in Florida, South Carolina, or Georgia's state waters. Landings included in the Florida Trip Ticket data may include landings of finetooth sharks that were caught by vessels using gillnet gear in Federal waters to target kingfish, however, it is difficult to differentiate because these trip tickets are not set-specific, rather, reflect the total landings sold to individual dealers. Of the vessels that were associated with these landings, six vessels had only a shark permit, three vessels had no permit, and eight vessels had both a shark and a Spanish mackerel permit reiterating the need for potential collaborative management efforts between HMS and the South Atlantic Fishery Management Council. Since the majority of commercially harvested finetooth sharks are landed and sold at dealers in Florida, it is critical that the Agency maintain close relations with personnel at the Florida Fish and Wildlife Commission and continue to receive updates on landings of finetooth sharks in order to determine the extent of finetooth shark mortality.

Alternative D4 would also expand data collection efforts by listing finetooth sharks as a select species with the Shrimp Trawl Fishery Observer Program, meaning that finetooth sharks will be included in observer sampling of bycatch in this fishery. Shrimp trawl vessels operate in shallow, inshore waters that are habitat for finetooth sharks. Including finetooth sharks as a select species would result in subsamples of bycatch, including identification, measurement, and estimates of interactions in this fishery which may facilitate future management actions to minimize bycatch of finetooth sharks in this fishery. Furthermore, since there was a lack of bycatch catch series data for finetooth sharks available for review during the 2002 SCS assessment, including this data in the future could improve precision of the model outputs for the next stock assessment and thereby the management recommendations. Increased attention to finetooth sharks on the behalf of the observers may result in inclusion of other HMS as select species in this observer program in the future, thereby, potentially improving estimates of interactions between HMS and trawl fisheries in the Gulf of Mexico and resulting in positive ecological impacts.

The United States Coast Guard (USCG) and Texas Parks and Wildlife Department (TXPWD) have informed NMFS that another source of undocumented finetooth shark fishing mortality occurs as a result of illegal fishing by Mexican gillnet vessels in the U.S. EEZ in the Gulf of Mexico. Seized catches have included finetooth sharks and NMFS would like to increase collaborative efforts to reduce this mortality as it may be impacting other species (HMS and non-HMS) as well.

De Silva *et al*. (2001) conducted a profile of shark bycatch in the U.S. Gulf of Mexico menhaden fishery in 1994 and 1995. Their findings indicate that finetooth sharks were landed in this fishery. They sampled 30 percent of the sets and found ten species of sharks, including six finetooth sharks. The authors indicate that small slender sharks (SCS and juvenile LCS) were less likely to be detected and identified in their sampling protocols. Since menhaden are a primary forage species of finetooth shark (Bethea *et al*., 2004), it is likely that some proportion of the small, unidentified bycatch in this fishery are finetooth sharks. This fishery is predominately located in state waters between Texas and Alabama and is not subject to observer coverage at this time. If observer coverage or some other means of monitoring bycatch were implemented in this fishery, it would be helpful to understand the extent to which finetooth sharks are being landed. However, NMFS does not have jurisdiction over state waters and can not implement these monitoring programs.

Finetooth sharks are difficult to properly identify; therefore, the shark dealer workshops preferred in this action (alternative A9) that focus on species identification may facilitate improved quota monitoring and ensure that data received from shark dealers are more accurate. Furthermore, since the SCS fishery is generally open year-round, and rarely approaches its allotted quota, there may be an incentive for shark dealers to intentionally misidentify LCS as finetooth sharks or other SCS to avoid exceeding regional trimester quotas for LCS. The Agency anticipates that outreach on the positive identification of sharks would provide shark dealers with the necessary tools and skills to be able to properly identify what they are purchasing from vessels, resulting in positive ecological impacts.

Alternative D4 would likely have long-term positive ecological impacts as it would implement a plan to prevent overfishing of finetooth sharks. Short-term ecological impacts would likely be neutral. Improved coordination between NMFS and Regional Fishery Management Councils, Interstate Marine Fisheries Commissions, states, and other management bodies would result in better collaborative efforts to manage fish that move between jurisdictional boundaries. Furthermore, since there may be fisheries that are lacking an FMP or other management measures and incidentally catching finetooth sharks (*i.e*., the fishery for kingfish), increased collaboration with other management entities may result in the inclusion of these fisheries into existing management initiatives, thereby, improving management and conservation efforts. Without knowing all of the sources of finetooth shark mortality, any action taken by NMFS may be misdirected and could result in negative ecological impacts if fishing effort were shifted to other fisheries. The activities detailed within the preferred alternative would implement an effective plan for preventing overfishing by first identifying sources of fishing mortality before implementing additional collaborative management measures, as appropriate, to avoid initiating actions that may be easily circumvented or may simply result in additional dead discards of finetooth sharks.

*Social and Economic Impacts*

Alternative D1 would likely not result in any adverse economic or social impacts as the status quo would not substantially modify or alter commercial or recreational fishing practices for finetooth sharks or other shark species.

Alternative D2 would implement trip limits, reduce quotas, and/or modify gear and gear deployment, all of which could have negative social and economic impacts. Implementing trip limits on directed SCS trips under alternative D2 may impose negative economic and social impacts on a gillnet vessels that target sharks or land them incidentally when targeting non-HMS. Vessels that possess directed shark permits but are targeting other finfish species may also experience negative economic and social impacts. However, because they are not targeting sharks, NMFS assumes that finetooth shark landings would comprise a small proportion of their landings and their economic and social impacts would be less those of fishermen targeting sharks. Both fishermen targeting sharks and those targeting other species may need to conduct additional trips in order to maintain current profits. Thus, these fishermen may have increased costs such as travel time and fuel. If fishermen do spend more time fishing as a result of the trip limit, this could have negative social impacts.

Modifying gillnet mesh size may result in negative economic impacts to a small number of gillnet vessels that target sharks. These vessels would have to replace existing gear in order to comply with any new mesh size requirements, as there is not currently a mesh size requirement in place outside of the Southeast U.S. Restricted Area. The Agency estimates that shark gillnet gear may range in cost from $8,000 to $20,000 (2004 dollars). Gillnet vessels not targeting sharks may be unaffected by new mesh size requirements and might experience a positive economic effect at the expense of the directed shark vessels, however, this would depend on whether gear restrictions were linked to possession of a shark permit. Vessels targeting king and Spanish mackerel already have minimum mesh size restrictions of 4.75 and 3.5 inches (12.1 and 8.9 cm), respectively. ALWTRT regulations define shark gillnet as being a minimum of 5 inches mesh size. Specifying maximum soak times for gillnet vessels targeting sharks may impose a negative economic effect as vessels would have to work longer hours and make more sets in order to maintain their current catch levels. Furthermore, a maximum soak time would also encourage fishermen to simply re-deploy gear after it has been hauled back if they had not yet caught enough fish. Fisheries targeting king and Spanish mackerel in Federal waters already have a one-hour maximum soak time for gillnets. Additional restrictions, coupled with increased fuel prices, would have negative economic impacts on the fishery.

Finally, alternative D2 would reduce the SCS quota. This may have a negative economic impact on the fishery depending on the amount of the quota reduction. A small reduction in the overall SCS quota may have no effect since the SCS quota has never been reached in a single year. Landings of SCS were 76.4 percent of the SCS quota of 326 mt dw in 2003 and, prior to that, SCS landings were less than 20 percent of the quota. The current SCS quota is 454 mt dw. The highest landings of SCS occurred in 1999 at 330 mt dw, or approximately 73 percent of the current quota. Therefore, the SCS quota would have to be reduced by more than 25 percent to have economic impacts on the shark gillnet fishery, or future landings would have to increase before a reduced quota would actually inhibit landings of SCS based on historical data. Furthermore, catch rates and restrictions implemented in other fisheries may also have economic impacts on the shark gillnet fishery. Reductions in the SCS quota of less than 25 percent would appear to have no negative impact on the fishery based on the current level of landings. However, since most finetooth sharks are observed dead or in poor condition at haulback, increasing the number of dead discards as a result of reducing the quota may have negative economic and social impacts.

Closing the shark gillnet fishery and removing gillnet gear from the list of authorized gear types would likely have significant negative economic impacts on the vessels currently engaged in this fishery but minimal impacts on the shark fishery as a whole. It would likely cause economic dislocation of at least five individuals or small entities and may put them out of business if there are not other fisheries from which they can substitute lost revenues as a result of this closure. However, as mentioned previously, there were 15 vessels that reported landing finetooth sharks in Federal logbooks in 2003. Furthermore, if gillnet were no longer an authorized gear for sharks, than presumably vessels that possess a commercial shark permit would not be able to possess sharks when gillnet gear is on board, even when targeting another species such as Spanish mackerel. Conversely, participants may sell their shark permits, target non-HMS, and discard any finetooth sharks that are landed. The economic impacts of closing the shark gillnet fishery are difficult to estimate as most of the vessels engaged in the directed shark gillnet fishery possess other permits. Furthermore, they would still be able to harvest sharks with other authorized gear types. The costs of refitting vessels to fish with BLL or other authorized gears would be extensive.

The five vessels participating in the directed shark drift gillnet (and/or strikenet) fishery are concentrated in the Ft. Pierce/Cape Canaveral region of southeast Florida. Therefore, there might be proportionately greater negative social or economic impacts on these vessels because a significant portion of their income comes from the harvest of sharks. Furthermore, these vessels may incur significant costs as they shift to other fisheries in order to maintain financial viability. Also, regulations in other fisheries may prohibit an increase in fishing effort.

Alternative D3 considers implementing recreational management measures such as a requirement to use circle hooks when targeting SCS in the recreational fishery. A circle hook requirement may result in negative economic impacts to the shark recreational fishery and related industries because a proportion of the fishery would have to switch to circle hooks from J-hooks. The Agency is not aware of the proportion of the recreational fishery that actually targets sharks in Federal waters since an HMS Angling permit allows participants to land tunas, certain species of sharks, swordfish, and billfish. A limited survey of hook prices indicated that J-hooks of the sizes and styles used by HMS recreational fishermen ranged in price from a low of $0.50 to a high of $7.50 each, with an average price of $2.70 (2004 dollars). Similarly, circle hooks of the sizes and styles used by HMS recreational fishermen ranged in price from a low of $0.30 to a high of $7.00 each, with an average price of $2.24 (2004 dollars). The Agency does not have information regarding the proportion of the recreational shark fishing community that is currently using circle hooks. It is assumed that fishing effort for sharks would remain relatively constant, as mandating circle hook use would not result in prohibitively high costs to remain in the fishery. Generally, the purchase of hooks represents only a minor capital expenditure relative to other costs associated with participating in marine fisheries, including the purchasing, equipping, maintaining, and running of vessels, which can cost thousands of dollars.

Under alternative D3, the Agency would increase the existing recreational size limit for finetooth sharks, which may have some negative social and economic impacts on near shore anglers and the supporting recreational industry. The social and economic impacts may vary depending on the willingness of anglers to release finetooth sharks caught and/or substitute harvested fish with other similar species. Angler expenditure data attained from MRFSS during 1998 – 2000 indicate that expenditures on excursions targeting small coastal sharks averaged $83.47/person/day (2004 dollars). NMFS does not believe that a minimum size increase would have an adverse impact on angler consumer surplus or satisfaction in recreational fisheries because finetooth sharks only comprise approximately 1.5 percent of the overall SCS recreational harvest. Encounters are relatively rare and few fishermen would target finetooth sharks. This alternative would not affect revenues to charterboat owners, captains, and others who rely on the recreational shark fishery. Tournaments would still be able to offer prize categories for finetooth sharks provided they are above the minimum size. In the long-term, as overfishing of finetooth sharks is eliminated, revenues may increase as less time would be required to catch finetooth sharks and as larger sharks increase in abundance. This alternative would not jeopardize participant safety, as recreational fishermen already have to determine the length of finetooth sharks relative to the existing minimum size.

Alternative D4 would not likely have significant social and economic impacts in the short-term as it primarily expands Agency efforts to discern sources of finetooth fishing mortality and would not enact additional management measures on fishing activities in recreational or commercial sectors at this time. The expansion of DSGFOP in 2005 resulted in an additional 88 sets on 30 trips from eight vessels. As per 50 CFR § Part 635.7, NMFS may select, for at sea observer coverage, any vessel that has an Atlantic HMS, tunas, shark or swordfish permit under §§ 635.4 or 635.32. Therefore, a stipulation of maintaining a commercial HMS shark permit requires that permit holders could be subject to observer coverage at any time. Selecting additional vessels for this coverage would not impart additional economic burden that has not already been analyzed. Furthermore, most gillnet trips targeting sharks or other non-HMS are in smaller vessels that generally do not stay out for extended periods of time, reducing the costs to individual vessel owners of providing food and accommodation comparable to their crew members. The number of additional vessels that fish with gillnet gear, possess a directed shark permit, and are not currently subject to observer coverage is estimated to be approximately ten vessels. It is difficult to estimate future numbers of vessels that might be subject to observer coverage as directed or incidental shark permit holders could deploy gillnet gear and become subject to observer coverage at any time. Vessels would be expected to attain the proper safety certification decals from the United States Coast Guard and ensure that there are adequate accommodations on board for observers prior to taking an observer; however, these requirements are already in place for the commercial shark fishery.

Efforts to record data on finetooth shark landings on shrimp trawl vessels would not result in any social or economic impacts because observer coverage would not be expanded. This observer program already exists and adding finetooth sharks to the select species list would not significantly impact the time required for observers to complete their sampling of bycatch in the trawl fishery. Furthermore, coordination with Regional Fishery Management Council, Interstate Marine Fisheries Commissions, and state agency staff regarding fisheries that may be contributing to finetooth shark fishing mortality would not result in any negative social or economic impacts to the public in the short term, and would likely result in long term social and economic benefits by determining where management measures should be enacted to reduce finetooth fishing mortality. Furthermore, collaboration with these entities may increase future collaborative efforts and result in additional landings information for other HMS species and protected resources that may be harvested in other fisheries.

*Conclusion*

The preferred alternative implements an effective plan to prevent overfishing by collecting data and identifying all sources of finetooth shark fishing mortality, expanding observer coverage in non-HMS fisheries, and creating a foundation for management measures that will effectively prevent overfishing of finetooth sharks. The majority of finetooth shark landings occur in commercial fisheries deploying a non-selective gear (gillnets) in a region (south Atlantic) where other non-HMS fisheries also deploy gillnets. Thus, measures that prohibit the use of gillnets for landing sharks (alternative D2), if aimed exclusively at the commercial shark gillnet fishery, would not prevent overfishing of finetooth sharks. Most of the five vessels that comprise the commercial shark gillnet fishery also possess Spanish mackerel permits. If gillnets were not allowed for the harvest of sharks the vessels could continue to deploy gillnets to catch other species, including Spanish mackerel, catch finetooth sharks incidentally, and then discard dead finetooth sharks. Without cooperative measures vessels may be able to circumvent any additional regulations that would be enacted for the commercial shark fishery when pursuing Spanish mackerel. Finetooth sharks are caught in a wide range of gillnet mesh sizes and are often dead at haulback, rendering trip limits and/or gear modifications (alternative D2) ineffective at preventing overfishing because dead sharks would continue to be discarded. Mortality of finetooth sharks in fisheries outside the jurisdiction of HMS (state waters) or in unregulated fisheries in Federal waters (*i.e*, kingfish) would also be unaffected. The preferred alternative will provide additional information on finetooth shark landings to allow enactment of comprehensive, collaborative measures that effectively reduce finetooth shark fishing mortality.

NMFS continues to explore which vessels may be engaged in fisheries that may harvest finetooth sharks and intends to conduct a new SCS stock assessment following the Southeast Assessment, Data, and Review process starting in 2007. Reducing finetooth shark fishing mortality via regulations targeting commercial shark permit holders is further confounded by the fact that finetooth sharks are one of the species in the SCS complex, which is not currently overfished or experiencing overfishing, and commercial fishermen have only caught, on average, 28.5 percent of the SCS quota between 1999 – 2003. Measures aimed at the recreational fishery (alternative D3) would only impact a small portion of the overall finetooth shark landings and, until comparative research on the merits of circle hooks versus J-hooks for reducing post-release mortality exists for sharks, implementing a circle hook requirement may be ineffective.

Furthermore, a conservative bag limit of one shark (including finetooth shark) and a minimum size above the age at first maturity for males and females is already in place.

As described in Table 2.1. and in this section, the plan for preventing overfishing of finetooth sharks detailed in the preferred alternative would first continue to identify fisheries contributing to finetooth shark mortality. This information may result in long-term positive ecological impacts not only on finetooth sharks but also other species. Information gathering and research have, and will continue to, provide valuable contacts, landings information, and improved understanding of fisheries that are being conducted in other management jurisdictions and may be beneficial for future collaborative measures between states, Regional Fishery Management Councils, Interstate Marine Fisheries Commissions, and NMFS. This plan also includes expanding observer coverage in the South Atlantic gillnet fisheries that are landing sharks incidentally and in the Gulf of Mexico shrimp trawl fishery which would provide substantive information on which fisheries are currently contributing to the majority of finetooth shark landings and would also provide bycatch data. Furthermore, working directly with the Regional Fishery Management Councils, Interstate Marine Fisheries Commissions, and states to identify all fisheries that may be interacting with finetooth sharks is a critical step to discern appropriate management options. Lastly, since finetooth shark carcasses can be difficult for shark dealers to positively identify, the workshops on shark identification, which would be implemented in alternative A9, would provide indirect benefits by improving the ability of shark dealers to positively identify finetooth sharks to species, and thus improve the accuracy of General Canvass logbooks received from dealers.

By first identifying sources of finetooth shark fishing mortality, the plan outlined in alternative D4 would facilitate potential collaborative, informed management measures that can best meet conservation and management goals while avoiding significant, and potentially unnecessary, economic and social impacts. Alternatives D2 and/or D3 (commercial and recreational management measures) may be considered in the future depending on any new information collected regarding finetooth shark landings, changes in the finetooth sharks status per the upcoming SCS stock assessment, new data on post-release mortality benefits of using circle hooks in recreational shark fisheries, or other relevant information that becomes available or is collected as a result of alternative D4.

As summarized in Appendix D, NMFS received a wide-range of comments from the public both supporting and opposing the preferred management measures. NMFS believes that the preferred alternative is a prudent means of developing comprehensive and collaborative regulations to prevent finetooth shark fishing mortality. NMFS received a range of public comments indicating support and opposition to alternatives D2-D4, and additional comments, including, but not limited to: comments on gillnet fisheries in general, the use of VMS, the results of the 2002 SCS stock assessment, reporting of HMS by dealers, identification of finetooth sharks, and the accuracy of data attained from MRFSS. All of these comments were considered prior to selection of the final preferred alternatives for preventing overfishing of finetooth sharks. Additional measures, possibly the commercial and recreational measures analyzed in this document, or others, may be necessary to prevent overfishing of finetooth sharks in the future.

### 4.2.3 Atlantic Billfish

As described in Chapter 2, the alternatives considered for the management of the directed Atlantic billfish fishery are:

E1 Retain existing regulations regarding recreational billfish fishing, including permit requirements, minimum size limits, prohibited species, landing form, allowable gear, and reporting requirements (No Action)

E2 Effective January 1, 2007, limit all participants in Atlantic HMS recreational fisheries to using only non-offset circle hooks when using natural baits or natural bait/artificial lure combinations

*E3 Effective January 1, 2007, limit all HMS permitted vessels participating in Atlantic billfish tournaments to deploying only non-offset circle hooks when using natural baits or natural bait/artificial lure combinations – Preferred Alternative*

E4(a) Increase the minimum legal size for Atlantic white marlin to a specific size between 68 and 71 inches LJFL (172 - 180 cm)

E4(b) Increase the minimum size for blue marlin to a specific size between 103 and 106 inches LJFL (261 – 269 cm)

E5 Implement a recreational bag limit of one Atlantic billfish per vessel per trip

*E6 Effective January 1, 2007, Implement ICCAT Recommendations on Recreational Marlin Landings Limits – Preferred Alternative*

E7 Effective January 1, 2007 – December 31, 2011, allow only catch and release fishing for Atlantic white marlin

E8 Effective January 1, 2007 – December 31, 2011, allow only catch and release fishing for Atlantic blue marlin

*Ecological Impacts*

Alternative E1 would maintain the *status quo* in the domestic recreational billfish fishery. This alternative would retain all existing regulations regarding recreational billfish fishing in the Atlantic Ocean, including permit requirements, minimum size limits, prohibited species, catch and release fishery management program, landing form, allowable gear, and reporting requirements, unless otherwise modified during this rulemaking. As discussed in additional detail below, alternative E1 would likely continue to provide minor ecological benefits for Atlantic billfish populations stemming from mandatory permitting requirements and minimum legal size limits. However, the No Action alternative would allow for the continued use of J-hooks in all segments in the fishery, which, as discussed in detail below, have been shown to have higher post-release mortality rates than previously estimated.

The two primary domestic sources of Atlantic billfish mortality include the Atlantic pelagic longline fishery and the directed recreational billfish fishery. Bycatch and discards of blue marlin, white marlin, and sailfish in the pelagic longline fishery show an overall decrease from 1999 to 2004, as seen in Table 3.20. There is no discernable trend for Atlantic spearfish. As seen in Figure 4.20 and Table 4.47, data reported to ICCAT for the period 1999 – 2004 shows a noticeable overall decrease in dead discarded Atlantic blue and white marlin and sailfish in the domestic pelagic longline fishery, with noticeable inter-year fluctuation for the marlins.

Trends in recreational landings of Atlantic billfish also show an overall decrease for the period 1999 - 2004, with substantial inter-year fluctuations, as shown in Figure 4.20 and Table 4.47. Landings of blue marlin clearly show an initial downward trend from 1999 - 2001 and a steady increasing trend from 2001 - 2004. Recreational landings of Atlantic blue marlin decreased from 1999 – 2001 from 36.9 mt to 16.4 mt. However, while the 2004 landings of Atlantic blue marlin were still below 1999 landings levels, landings of blue marlin increased steadily from 16.4 mt in 2001 to 24 mt in 2004.

As shown in Figure 4.20 and Table 4.47, during the period 1999 – 2004, mortality of Atlantic blue marlin resulting from pelagic longline dead discards exceeded recreational mortality attributable to recreational landings, in most years. The exception was in 2003 when pelagic longline dead discards and recreational landings were equivalent. Dead discards of Atlantic white marlin from pelagic longline fishing substantially exceeded recreational landings of white marlin each year during this period. Conversely, recreational landings of Atlantic sailfish substantially exceeded pelagic longline dead discards each year during this period. From 1999 to 2004, the difference between pelagic longline dead discards and recreational landings has narrowed.

Domestic recreational Atlantic billfish catch (landing and release) statistics are less robust than commercial catch statistics. This is due to a number of factors including the sheer number of recreational vessels (*e.g.*, 25,238 Angling category permits; 4,173 CHB permits), the widespread and diffuse nature of the fishery, less stringent reporting requirements in the recreational HMS fishing sector than the commercial sector, a lack of observer coverage on recreational vessels, and significant non-compliance with recreational non-tournament reporting requirements. Identifiable gaps in self-reported non-tournament landings data include, but are not limited to, blue marlin landings in Puerto Rico and swordfish landings in the mid-Atlantic region. An examination of the Atlantic recreational billfish and swordfish reporting database shows that non-compliance or limited compliance with reporting requirements is occurring throughout the recreational swordfish and billfish fishery. For example, in 2004, swordfish landings were reported in only Florida, Alabama, and Rhode Island. A review of sportfishing magazines, local newspapers, and internet fishing websites indicates non-reported landings in many states. Further, NMFS staff are regularly informed by participants in the sportfishing community that compliance with non-tournament HMS reporting requirements is low. Similar comments were also received during the public comment period on the Draft Consolidated HMS FMP. As a result, non-tournament recreational billfish statistics are considered minimum estimates and actual landings may, in fact, be higher. NMFS is working to improve compliance with reporting requirements through various outreach efforts, including distribution of outreach materials, participating in national, regional, and local meetings with constituents, and increasing enforcement of reporting violations.

Minimum size limits are the primary management measure currently in effect to limit landings and potentially limit total fishing mortality in the directed fishery for Atlantic billfish. The current minimum size limits can reduce the number of fish that qualify for landing. Current minimum size limits were implemented to decrease domestic landings in an effort to comply with ICCAT Recommendation 97-09. In addition to limiting fishing mortality by potentially reducing the number of fish landed, if set appropriately, minimum sizes can also ensure some level of reproductive potential remains in the fishery by allowing fish to reach the size at sexual maturity before recruiting into the fishery, where they are eligible for landing. Current domestic minimum sizes are set above the size at maturity for Atlantic blue marlin, white marlin, and sailfish, and, as such, assure that some level of reproductive potential is maintained in the fishery. Additional increases in minimum sizes or a shift to catch and release fishing, as per preferred alternative E6, while potentially increasing the number of released fish would further assure that some level of reproductive potential is maintained in the fishery. Minimum size limits do not, in and of themselves, guarantee that landings will remain at any given level or have a direct impact on post-release mortality of billfish. Billfish that are released in the recreational fishery are not considered as bycatch because of the catch-and-release fishery management program that was established in Amendment 1 to the Atlantic Billfish FMP (NMFS, 1999).

Known recreational landings of Atlantic billfish have remained at relatively low levels since 1999 due to minimum sizes requirements and a strong voluntary adherence to the practice of catch and release fishing. Recent recreational landings, as reported to ICCAT in metric tons, can be seen in Table 4.47 above, and as previously noted, reflect a steady increase in estimated landings of Atlantic blue marlin from 2001 - 2004. The number of recreationally landed Atlantic blue and white marlin, as reported to ICCAT, since adoption of the annual 250 recreationally caught marlin landing limit (Recommendation 00-13), can be seen in Table 4.48. In 2002, the United States exceeded its combined annual limit of 250 recreationally landed blue and white marlin, but carried forward underharvest from 2001, per ICCAT Recommendation 00-14. ICCAT Recommendation 00-14 allows for the carryover of underharvest and mandates carryover of overharvest from a previous fishing year to a subsequent fishing year for any species under quota or catch limit management. It should be noted that the accounting methodology upon which the 2003 numbers reported to ICCAT were based differs from the methodology used to generate the 2002 and 2001 numbers that were reported to ICCAT. The methodology used to generate the 2001 and 2002 landings shown in Table 4.48 resulted in higher landings being reported to ICCAT for those years than would have been reported if the 2003 methodology had been applied. For additional information on this methodological issue, please see Van Voorhees *et al*., 2004.

As previously discussed, recreational billfish data are less robust than commercial data. There are several sources of recreational data with overlapping samples. Each data source provides a unique view of billfish fisheries, including both landed and released fish. Recreational Billfish Survey (RBS) data represent the majority of verifiable domestic Atlantic billfish landings and can be seen in Table 4.49. The RBS was designed to provide a complete census of tournament landings, and as such, it is considered to be both accurate and precise in this regard. However, it is important to note that the RBS represents a subset of total billfish landings and, as such, includes certain biases. Because the RBS captures only tournament landings it is, by design, a subset of aggregate U.S. landings. Further, given that tournament fishermen do not, as a general rule, land a fish that is smaller than one that has already been landed in a tournament, both the size of tournament reported fish and the release percentages that can be calculated from RBS data are likely biased high relative to the fishery as a whole.

Another source of recreational billfish data is the Marine Recreational Fishery Statistics Survey (MRFSS). MRFSS includes Atlantic HMS, but was not specifically designed for HMS fisheries, which are considered rare event fisheries in comparison to inshore fisheries such as red drum. Further, MRFSS does not cover the State of Texas. For these reasons, the MRFSS data are not considered to be highly accurate in determining the exact number of landings or releases of Atlantic HMS, but it does provide useful additional data for purposes of comparison with other data sets. The Large Pelagics Survey (LPS) is another statistical sampling survey that includes Atlantic HMS. This survey was designed to intercept BFT and operates only from Virginia to Maine on the Eastern seaboard from June through October. As such, LPS landings data are known to be a subset of aggregate U.S. Atlantic landings. Both the MRFSS and LPS can overlap with the RBS data, which must be accounted for when attempting to quantify aggregate landings. Finally, the HMS Management Division operates the Atlantic HMS non-tournament billfish and swordfish reporting line which is intended to capture non-tournament landings of all billfish and swordfish. With the exception of billfish or swordfish landed in the States of North Carolina and Maryland, anglers landing Atlantic billfish or swordfish outside of tournaments are required to report those landings to NMFS with 24 hours of landing. The States of North Carolina and Maryland have landing card programs in place and provide their landings data to NMFS.

The directed billfish fishery is primarily catch and release in nature. Fisher and Ditton (1992) estimate that between 74 and 99 percent of all billfish are released by billfish anglers in general. RBS data, as presented in Table 4.49, indicate Atlantic HMS tournament release rates of 89.9 to 93.3 percent for blue marlin, 96.8 to 99.2 percent for white marlin, and 98.5 to 99.6 percent for sailfish for the period 1999 - 2004. MRFSS data, as presented in Table 4.50, indicate release rates of 75.8 to 100 percent for blue marlin, 99.6 to 100 percent for white marlin, and 93.5 to 99 percent for sailfish, for this same period. LPS data, as presented in Table 4.51 indicate release rates of 87 to 100 percent for blue marlin, 89.4 to 99.4 percent for white marlin, and zero to 100 percent for sailfish, for the same period. Obviously, the estimates pertaining to sailfish (0 to 100 percent) indicate the wide variability in some data sets. Nevertheless, the preponderance of available data indicate a strong adherence by Atlantic billfish anglers, whose activities are captured by these data collection systems, to catch and release fishing, both within and outside of tournaments.

Despite the widespread practice of catch and release fishing in the Atlantic billfish fishery, as discussed above, recent data on post-release mortality rates of recreationally caught billfish indicate that the adverse ecological impacts of recreational activities on billfish resources may be greater than previously recognized. Post-release survival of recreationally caught and released Atlantic billfish was previously estimated to be 90 percent or greater (NMFS, 1999). Conversely, this means that post-release mortality of recreationally caught and released billfish was previously estimated to be ten percent or lower. This estimate was derived from a review of the relevant literature at the time, which consisted primarily of studies examining catch and release mortality of bluefin tuna and sharks and Gulf of Mexico longline post-release survivorship. Since that time, there have been a number of pertinent studies examining both J-hook and circle performance and effects on billfishes.

A recent study by Horodysky and Graves (2005) examining the post-release mortality in the recreational fishery for Atlantic white marlin strongly suggests that mortality levels using traditional J-hooks may be higher than previously assumed. Horodysky and Graves found that the mortality rate of white marlin associated with J-hooks was 35 percent. This number was higher than post-release mortality rates for other billfish species. Horodysky and Graves (2005) noted post-release mortality rates (from other studies)of 11 percent for blue marlin and 29 percent for striped marlin caught with this hook type. Given sample sizes of the studies examined, there is no statistical difference between the Horodsyky and Graves 35 percent post-release mortality rate for Atlantic white marlin and the 29 percent estimate identified for Pacific striped marlin. As discussed above, previous post-release survival estimates for billfish were thought to be in excess of 90 percent. The recent white marlin post-release mortality statistics, when combined with estimates for the number of Atlantic blue and white marlin released by U.S. anglers, form the basis for NMFS' conclusion that the mortality contribution of the recreational billfish fishery is higher than previously estimated.

Table 4.52 presents the estimated number of white marlin mortalities resulting from catch and release fishing activities based on NMFS' RBS, MRFSS, and LPS databases. In deriving these estimates, an assumption was made that all billfish anglers use J-hooks. NMFS acknowledges that some unquantified portion of billfish anglers currently use circle hooks, and, as such, this assumption could bias the estimates to higher than actual levels. NMFS currently does not have an estimate of the proportion of billfish anglers that regularly use circle hooks. However, uncertainty in billfish landings stemming from under-reporting, as well as additional uncertainty stemming from landings estimates in the Commonwealth of Puerto Rico and the U.S.V.I., may result in underestimates of recreational mortality. Mortality estimates were derived by applying a post-release mortality rate of 0.35 (Horodysky and Graves, 2005) to the reported number of releases (*e.g.*, 100 $_{\text{releases}}$ * 0.35 $_{\text{post-release mortality rate}}$ = 35 $_{\text{mortalities}}$). Using this methodology, estimated release mortalities of Atlantic white marlin range from 215 to 773 based on RBS data (1999 – 2004), 119 to 3,939 based on MRFSS data (1999 – 2004), and 55 to 1,966 for LPS data (1999 – 2004). For the reasons discussed above, actual post-release mortalities of white marlin likely fall somewhere between these estimates. As previously discussed, each of these databases has particular limitations, however, taken in combination, the data provide some indication of the magnitude of U.S. induced recreational white marlin mortalities.

*Incomplete data available for these years for this data set.

Table 4.53 presents the estimated number of Atlantic blue marlin mortalities resulting from catch and release fishing activities based on the RBS, MRFSS, and LPS databases. Estimates were derived by applying a post-release mortality rate of 0.11 (Graves 2002) to the reported number of releases (*e.g.*, 100 $_{\text{releases}}$ * 0.11 $_{\text{post-release mortality rate}}$ = 11 $_{\text{mortalities}}$). Consistent with the calculations for white marlin above, NMFS assumed that all billfish anglers use J-hooks. NMFS acknowledges that some billfish anglers currently use circle hooks, and, as such, this assumption could bias the estimates to higher than actual levels. NMFS currently does not have an estimate of the proportion of billfish anglers that regularly use circle hooks. However, uncertainty in billfish landings stemming from under-reporting, as well as additional uncertainty stemming from landings estimates in the Commonwealth of Puerto Rico and the U.S.V.I., may result in underestimates of recreational mortality. Between 1999 and 2004, estimated post-release mortalities of Atlantic blue marlin range from 114 to 169 fish based on RBS data, and 274 to 765 fish based on MRFSS data. Between 1999 and 2004, estimated post-release mortalities of Atlantic blue marlin ranged from 3 to 207 fish for LPS data. It is likely that the true post-release mortalities of blue marlin fall somewhere between these estimates. As previously discussed, each of these databases has particular limitations, however, taken in combination, the data indicate that U.S. induced mortalities of Atlantic blue and white marlin are likely higher than previously assumed in Amendment 1 to the Billfish FMP (NMFS, 1999).

*Incomplete data available for these years for this data set.

As previously stated, alternative E1 would likely continue to provide only minor ecological benefits, given the limited measures (permit requirements and minimum size limits) currently in place to limit fishing mortality by limiting landings. Nevertheless, the ecological benefits of alternative E1 would be substantially below those of other billfish alternatives presented in this document. Minimum sizes alone cannot directly limit landings or mortalities, but can indirectly limit landings by limiting the available pool of legal sized fish. Continuation of existing management measures would likely provide a low level of positive ecological impacts for Atlantic billfish by constraining increases in billfish landings and thereby limiting mortality to some extent. However, new data on the post-release mortality of white marlin, as discussed above, indicate a larger contribution by U.S. recreational anglers to Atlantic-wide white marlin mortality rates than assumed in Amendment 1 to the Atlantic Billfish FMP (NMFS, 1999). Alternative E1 would not likely result in any substantial change in the number of Atlantic billfish landed, released, or discarded dead, or result in any significant change in the current levels of post-release mortality in the near future. Under the No Action alternative, landings, dead discards, and post-release mortality attributable to the directed billfish fishery could increase or decrease depending on angler behavior, with negative or positive ecological impacts given that there are no management measures currently in place to directly control landings or effort. However, no shifts in angler behavior are anticipated under the No Action alternative. NMFS received limited public comment in support of the No Action alternative, which generally cited existing domestic regulations as being appropriate and suggested the additional regulation would be inappropriate. Commenters further suggested that voluntary use of circle hooks could increase. However, as previously, discussed the No Action alternative would allow for the continued and restricted use of J-hooks in the recreational fishery, which are associated with significantly higher post-release mortality rates than previously estimated. Alternative E1 would likely not reduce or reverse the current United States' or Atlantic-wide fishing mortality rates for either blue or white marlin. Further, the No Action alternative cannot, in and of itself, ensure compliance with the ICCAT marlin landing limit. For these reasons, despite limited public support for it, NMFS is not preferring the No Action alternative. Alternative E1 is not anticipated to increase or decrease interactions with protected resources including sea turtles, seabirds, or marine mammals, or impact non-target species because no changes in fishing effort or practices would be expected.

Alternative E2 would require the use of non-offset circle hooks in all segments of HMS recreational fisheries, for all species, whenever natural baits or natural bait/artificial lure combinations are used, beginning on January 1, 2007. This includes HMS Angling category permitted vessels, Charter/Headboat permitted vessels when on a for-hire trip or fishing recreationally, and all General category permitted vessels participating in registered HMS tournaments. Circle hooks are defined in 50 CFR §635.2 as "a fishing hook originally designed and manufactured so that the point is turned perpendicularly back to the shank to form a generally circular, or oval, shape." Natural bait/artificial lure combinations would include, but would not be limited to, rigs such as natural baits used in combination with artificial hoods, heads, and/or skirts. This alternative could reduce the overall mortality rates of Atlantic white marlin, blue marlin, sailfish, and other species with which HMS fishermen interact by reducing post-release mortality rates. Alternative E2 would allow the use of J-hooks with artificial lures. NMFS received public comment during scoping, on the pre-draft document, and on the Draft Consolidated HMS FMP, that fishermen tend to target white marlin and sailfish with natural baits while either drifting or slow trolling and target blue marlin by trolling at a higher rate of speed with the fish striking at the lure. Because of these fishing practices and feeding habits, it is believed that blue marlin have less opportunity to deeply ingest baits, therefore resulting in a higher proportion of hook-ups in the mouth with less damage to vital tissues and lower rates of post-release mortality. In a study evaluating pop-up satellite tags for estimating post-release survival of blue marlin from a recreational fishery, Graves *et al.*, (2001) mouth hooked seven of nine blue marlin tagged by trolling at high speed using high speed lures or skirted dead baits with J-hooks. The remaining two fish were foul hooked. Commenters also strongly suggested that given the feeding habits of blue marlin, mandating circle hooks on artificial lures would significantly reduce the viability of trolling for blue marlin. Given the relatively low post-release mortality rate of recreationally released Atlantic blue marlin (approximately 11 percent) and substantial public comment requesting continued use of J-hooks for targeting Atlantic blue marlin, NMFS developed alternatives to allow the continued use of J-hooks with artificial lures.

Alternative E2 would likely provide positive ecological benefits for most, if not all HMS species with which recreational fishermen interact. This alternative would be expected to reduce mortality in the directed billfish fishery by reducing post-release mortality. There is mounting evidence that hook choice can significantly impact fishing mortality rates. In a review and analysis of 43 previous post-release circle hook studies, Cooke and Suski (2004) found that circle hooks resulted in lower fishing mortality than other types of hooks and that mortality was consistently higher for J-hook caught fish. Factors identified as affecting mortality of released fish included hooking depth, anatomical hooking location, bleeding, and ease of hook removal. Cooke and Suski (2004), Prince *et al.* (2002), and Horodsky and Graves (2005) found that J-hook caught fish were more likely to be deep hooked than circle hook caught fish, circle hooks were more likely to result in jaw hooking than J-hooks, and J-hooks were more likely to cause tissue trauma resulting in bleeding. The reduced occurrence of deep hooking associated with circle hooks as compared to J-hooks reduces the opportunity for damage to vital organs and excessive bleeding. Cooke and Suski (2004) found that, in general, hooking mortality rates were reduced by approximately 50 percent by using circle hooks relative to J-hooks. The authors attributed the mortality reduction associated with the use of circle hooks to the tendency of circle hooks to jaw-hook fish, resulting in shallow hooking depths. Cooke and Suski (2004) also recommend that management agencies implement circle hook requirements only in instances in which appropriate scientific data for similar species exists. Nevertheless, taken in aggregate, the available science indicates that hook type can have a significant effect on survival of released fish.

In another recently released study on circle hooks, J-hooks, and drop-back time, Prince *et al.*, (2006), evaluated the performance of non-offset circle hooks and a similarly sized J-hook used in the south Florida recreational live bait fishery for Atlantic sailfish. Sampling a total of 766 sailfish (392 caught on circle hooks; 374 caught on J-hooks), Prince *et al.* (2006) found that in terms of catch, hook locations, bleeding, and release condition, the traditionally-shaped circle hooks had the best performance with respect to conservation benefit for promotion of live release. Further, Prince *et al.* (2006) found that traditional circle hooks, those with curvature of the shank which allows for a generally circular or oval shape, as opposed to J-hooks that simply have the point of the hook turned back toward the shank and labeled circle hooks, performed well with drop back times of varying intervals. While the Prince *et al.* (2006) did not examine post-release mortality data, the findings of the study reinforce the findings of other studies that traditionally shaped circle hooks may contribute to reductions in post-release mortality rates of Atlantic billfish by improving hooking locations, reducing bleeding, and improving release condition. As stated in Prince *et al.*(2006); "The general conclusion to be drawn from both studies [Horodysky and Graves 2005 and Prince *et al.* 2006] is that non-offset circle hooks promote live release in dead bait troll fisheries targeting white marlin and sailfish and that J-hooks do not." The study further found comparable catch rates between circle and J-hooks, which is key to acceptance of circle hooks among anglers.

Also as previously discussed, Horodysky and Graves (2005) identified a post-release mortality rate of 35 percent (range 15 – 59 percent) for recreationally caught Atlantic white marlin when J-hooks were used. During this study, 7 of 20 white marlin caught on J-hooks died, while none of the 20 white marlin caught on circle hooks died. It is not a reasonable assumption that all circle hook caught white marlin will survive the catch and release experience, in every instance. Based on data from the same study, Dr. John Graves (pers. comm.) indicated that the research team identified a post-release mortality rate of 0 - 12 percent for Atlantic white marlin caught on circle hooks based on use of a statistical model and 10,000 runs of the data. This provides an estimated post-release survival rate of 88 - 100 percent. Assuming a worst case scenario where 12 percent of all Atlantic white marlin caught on circle hooks die, this provides an overall net mortality benefit to the fishery of approximately 23 percent (35 percent J-hook post-release mortality estimate - 12 percent circle hook post-release mortality benefit) for circle hook caught white marlin over J-hook caught marlin. In a relative sense, J-hook mortality versus circle hook mortality, it provides a 65.7 percent reduction ($12_{\text{percent circle hook post-release mortality estimate}}/35_{\text{percent J-hook post release mortality estimate}}$ = .343 percent). NMFS received public comments concerned that the Agency had drawn conclusion regarding the impacts of circle hooks on billfish based on the limited sample size in some studies, however, the research utilized in this document represents the best available science, including sample size and accurate replication of standard billfish angling methods.

Table 4.54 provides a retroactive estimate of the net mortality benefit for Atlantic white marlin of switching the entire recreational Atlantic white marlin fishery to circle hooks from J-hooks. In developing these estimates, NMFS applied the median post-release mortality rate of 35 percent (range 15 – 59 percent) for Atlantic white marlin caught recreationally on J-hooks against the upper bound post-release mortality estimate for Atlantic white marlin caught on circle hooks of 12 percent, as identified by Horodysky and Graves through modeling. NMFS received comment that a more statistically appropriate comparison would be to compare "central tendencies" of the post-release mortality estimates derived for J-hook and circle hook post-release mortality, *e.g.* the 35 percent estimate for J-hook mortality and 0 percent for circle hook mortality. However, for purposes of analysis in this Final Consolidated HMS FMP, NMFS believes that comparison of the median or central tendency, 35 percent value and the upper bounds of the circle hook post-release mortality estimates are appropriate for the reasons discussed below. NMFS agrees that the median 35 percent estimate developed for J-hook caught fish is most appropriate to use in developing estimates of post-release mortality of Atlantic white marlin in the fishery. For circle hooks, the observed rate mortality rate was 0. However, it is not realistic to assume that every fish will survive the catch and release experience when circle hooks are used, despite the observed rate of 0 during the study. Through statistical modeling, the researchers developed an upper estimate of 12 percent post-release mortality. The "central tendency" estimate generated from the modeling was zero. Given the fact that some fish caught and released on circle hooks will die, NMFS believes that, for purposes of analysis, it is appropriate to use the more biologically precautionary 12 percent estimate figure in combination with the 35 percent estimate for J-hook caught fish. NMFS will continue to refine its mortality estimates as new data become available.

In applying the circle hook mortality benefit to previous release estimates, the estimated mortality benefit (fish conserved) for white marlin ranged from 141 to 508 fish using RBS data, 78 to 2,589 fish using MRFSS data, and 36 to 1,292 fish using LPS data. Under alternative E2, NMFS estimates that approximately 88 percent of future released white marlin would survive as a result of being caught on circle hooks. Averaging the annual mortality reduction benefits identified in Table 4.54, NMFS estimates that alternative E2 could result in the annual savings of approximately 303 (range: 141 – 508) Atlantic white marlin according to RBS data, 1,297 (range: 78 – 2,589) white marlin based on MRFSS data, and 607 (range: 36 – 1,292) white marlin using LPS data, when compared to continuing use of J-hooks throughout the fishery (alternative E1). Again, estimates are based on the assumption that all or nearly all white marlin are currently caught on J-hooks. Presently, NMFS cannot accurately estimate the proportion of anglers using J-hooks or circle hooks. Given that some unquantified subset of Atlantic white marlin is currently captured on circle hooks, the actual ecological benefits may be somewhat below these estimates. However, unquantified non-compliance with landings reporting requirements may have the opposite effect and the actual ecological benefits may be somewhat above these estimates. Some limited but unquantified proportion of white marlin may become tail-wrapped and suffocate, suffer predation from sharks, or be caught on J-hook rigged artificial lures, which could also reduce post-release benefits. Tail-wrapping and predation occur in association with J-hook caught fish also.

The ecological benefits ultimately derived from circle hooks are somewhat dependent upon angler behavior and fishing techniques. Variables include decisions by the angler to retain a fish caught on a circle hook, off-setting hooks, or allowing circle hooks to be deeply ingested, all of which can influence mortality benefits associated with circle hooks. The use of offset hooks appears to be a key variable influencing mortality levels associated with circle hooks. Prince *et al.* (2002) found that highly offset (15 degrees or greater) hooks were associated with deep hooking, whereas minor (four degrees or less) and non-offset hooks were typically associated with jaw hooking. Overall, Prince *et al*. (2006) found highly offset hooks were approximately three times more likely to result in deep hooking for sailfish. Another variable that likely impacts survival is drop-back time, depending on hook type. When "dropping back", an angler free spools the bait, allowing the fish to deeply ingest the hook prior to setting it. As previously discussed, Prince et al. (2006) found that traditionally shaped circle hooks performed well (meaning they had a low rate of hooking in undesirable locations) under drop-backs of differing periods of time. The study showed that J-hooks and non-traditional circle hooks had elevated rates of undesirable hooking locations associated with drop-back relative to traditionally shaped circle hooks. Drop-back practice may result in higher rates of deep hooking and likely to higher rates of damage to internal organs when used with J-hooks and non-traditional circle hooks.

* Partial data available this data field.

As mentioned above, alternative E2 would likely result in positive ecological benefits for most, if not all, HMS species with which recreational fishermen interact. Cooke and Suski (2004) found circle hooks to be broadly beneficial in reducing mortality and/or improving hooking location when compared to J-hooks. As discussed, hooking location is a key variable in post-release mortality. Additional studies examined during this analysis reinforce these conclusions, specifically for HMS, including Atlantic white marlin (Horodysky and Graves, 2005), sailfish (Prince *et. al*., 2002), and bluefin tuna (Skomal *et*. *al*., 2002).

NMFS received substantial public comment opposing and supporting circle hook requirements, as proposed under draft alternatives E2 and E3, for a number of reasons. A prevalent theme contained in comments opposing mandatory circle hook use, in all or portions of the HMS and billfish recreational fisheries, was that the recreational sector has a minor impact on Atlantic billfish populations relative to the commercial pelagic longline fleet. From an international perspective, data reported to ICCAT indicate that commercial fishing activities are responsible for the majority of Atlantic billfish mortality (Kerstetter, 2006). However, given the relatively small size of the U.S. domestic pelagic longline fleet and the considerable size of the recreational fishing fleet (discussed in detail below), NMFS determined that it was appropriate to examine the issue of pelagic longline versus recreational mortality contributions from the domestic perspective.

To further explore this issue, NMFS examined data from the pelagic longline logbook program and the RBS, MRFSS, and LPS databases. Utilizing new information on recreational and commercial post-release mortality rates (Horodysky, 2005, and Kerstetter, 2006, respectively), an examination of the data by NMFS indicates that, in some years, the total mortality contribution of the domestic recreational billfish fishery may equal or exceed the total mortality contribution of the domestic pelagic longline fleet with regard to Atlantic white marlin. As seen in Appendix C, estimates of total annual recreational white marlin mortality, which combines landings, dead discarded fish, and estimated post-release mortalities of white marlin released alive, vary greatly by data set and year. MRFSS and LPS databases indicate that for the period 2001 – 2004, inclusive, the aggregate level of recreational mortality was approximately three and two times higher, respectively, than the aggregate mortality contribution (dead discards and estimated post-release mortality) of the domestic pelagic longline fleet with regard to Atlantic white marlin. Using RBS data, a known subset of recreational effort and landings, estimated aggregate recreational white marlin mortality appears to be about 71 percent of estimated total domestic pelagic longline white marlin mortality (based on logbook data) for the same period. When taken in combination, and allowing for the limitations and uncertainty associated with each database involved, two conclusions can be drawn; 1) the aggregate recreational fishing mortality contribution is higher than previously thought with regard to Atlantic white marlin and 2) there is more parity between the mortality contributions of the domestic recreational and domestic pelagic longline fleet than previously thought. Cramer (2005) and Kerstetter (2006) examined this same issue to varying degrees. Both papers support the same basic finding drawn in this Final Consolidated HMS FMP, that in some years the domestic recreational billfish fishery may impose equivalent or even greater levels of mortality on Atlantic white marlin populations than the domestic pelagic longline fishery.

Under initial examination, it appears that this may primarily be the result of the size differential between the two fisheries. As of February 1, 2006, there were 25,238 HMS Angling category permit holders and 4,173 HMS Charter/Headboat category permit holders able to legally pursue Atlantic billfish. An additional 4,824 General category permit holders can legally pursue Atlantic marlin while participating in registered HMS tournaments. Further, NMFS believes that the number of HMS Angling category permit holders, and perhaps CHB category permit holders, are lower than the actual number of vessels participating in the fishery *(i.e.* some unpermitted vessel may be illegally participating in the fishery). In contrast, as of February 1, 2006, the total number of vessels that could potentially participate in the pelagic longline fishery for HMS was 277, given the limited access permit system in place. The number of active pelagic longline vessels participating in HMS fisheries in 2004 was just 116, and fell to 110 in 2005. NMFS will continue to examine this issue as additional data become available. This data reinforces NMFS preferred alternative that it is appropriate to implement circle hook requirements in some segments of the recreational fishery, at this time, to reduce post-release mortality associated with the directed billfish fishery.

A second important theme in comments opposing mandatory circle hook use under alternatives E2 and E3 was the need for NMFS to promulgate more detailed specifications for circle hooks. Current regulations provide a definition of a circle hook: A circle hook means a fishing hook originally designed and manufactured so that the point of the hook is turned perpendicularly back toward the shank to form a generally circular or oval shape. Currently, there are no industry standards with regard to circle hook specifications, including size, degree of circularity, gap width, wire gauge, or other measurements. As such, NMFS is unable to provide an index of detailed hook specifications for each size circle hook that could be used in the recreational billfish fishery, at this time. NMFS is continuing to work on a more refined hook definition for the future. However, as per preferred alternative E3, NMFS finds that it is appropriate to require the use of circle hooks in portions of the recreational billfish fishery at this time in an effort to reduce post-release mortalities in the recreational billfish fishery.

Declines in post-release mortality of any overfished HMS stock would result in positive ecological benefits. Positive ecological gains (*i.e.*, reducing fishing mortality rates) would be relevant to considerations in the anticipated 2007 ESA Status Listing Review for Atlantic white marlin. As shown in Table 4.54, alternative E2 could decrease Atlantic white marlin mortalities by between 303 to 1,297 fish annually, on average, assuming no significant changes in effort or angler behavior, and exclusive use of natural bait/circle hook combinations. NMFS does not expect any significant changes in effort or angler behavior, but acknowledges that not all anglers will always use circle hooks and natural baits when J-hooks with artificial lures remain an option. Given these assumptions, the potential ecological benefits could be somewhat below the numbers stated above. However, given data limitations on recreational catches and releases, the actual number of releases may be higher than those that are presented in the tables above, thereby resulting in a larger ecological benefit than identified above. The overall ecological impact of alternative E2 would be positive, but limited, given the relatively small contribution of U.S. anglers to total Atlantic-wide mortality. As such, alternative E2 would likely reduce the current Atlantic-wide fishing mortality rates for both blue or white marlin to some degree, but would not be capable of decreasing the Atlantic-wide fishing mortality rate to $F_{msy}$. While the benefits of requiring circle hooks are loosely quantifiable for Atlantic white marlin, the benefits remain unquantifiable at this time for other species. As mentioned, Skomal *et al.* (2002) noted improved hooking location associated with circle hooks, which as discussed, may contribute to a reduced post-release mortality of bluefin tuna as compared to J-hooks. Still, there are relatively few data available on the efficacy and impacts of using circle or J-hooks on sharks, other tunas, and swordfish, which could be used to quantify impacts on these species.

Alterative E2 would likely have limited positive ecological benefits for blue marlin given fishing techniques for, and feeding behavior of, this species. As previously discussed, blue marlin are typically targeted by trolling lures or rigged natural baits at high speed. As a result, blue marlin are often mouth or foul hooked, as they aggressively strike and bat at the lures. As a result, many anglers would likely make use of an artificial lure rigged with a J-hook when fishing for blue marlin to improve the odds of success. This would be allowable under alternative E2. Potential ecological benefits derived from the use of circle hooks stemming from improved hooking location and reduced tissue damage may be undermined by angler actions including offsetting hooks, or using non-traditional circle hooks which may lead to higher rates of deep hooking and internal injury. Furthermore, as previously discussed, while Cooke and Suski (2004) suggest that overall post-release mortality rates are often lower when using circle hooks compared to J-hooks they also recommend that management agencies implement circle hook requirements only in instances in which appropriate scientific data exists for similar species.

Alternative E2 would not be expected to increase interactions with protected resources. NMFS has little or no data showing interactions between the directed Atlantic billfish fishery and protected species. NMFS' HMS Management Division has received one anecdotal report of such an interaction since late 2002. Thus, interactions between the directed Atlantic billfish fishery and protected species appear to be extremely rare. However, this alternative may contribute to a reduction of interactions as well as the mortality rates associated with any such interactions that may occur based on the hooking mechanics, improved hooking location, and decreased damage of vital tissues generally associated with the use of circle hooks.

Alternative E3, a preferred alternative, would require the use of non-offset circle hooks by anglers fishing from HMS permitted vessels and participating in an Atlantic billfish tournament whenever natural baits or natural bait/artificial lure combinations are deployed, effective January 1, 2007. Any tournament as defined under 50 CFR §635.2 that has an award category, or awards points or prizes for Atlantic billfish is considered a billfish tournament. Natural bait/artificial lure combinations would include, but are not limited to, rigs such as natural baits used in combination with artificial hoods, heads, and/or skirts. This alternative would allow the use of J-hooks with artificial lures in tournaments for the reasons discussed under alternative E2.

As noted in Chapter 2, NMFS has made a slight technical adjustment to the phrasing of alternative E3 in this Final Consolidated HMS FMP. NMFS received public comment expressing concern that HMS circle hook requirements may apply to all tournament participants, even non-HMS fishermen participating in large tournaments that may have award categories for species other than HMS. NMFS appreciates this concern and has refined the phrasing of the alternative to more accurately reflect the intent of this alternative. NMFS did not intend, nor mean to imply, that regulations governing 50 CFR part 635 would apply to fisheries under the jurisdiction of the Regional Councils. It should be noted that NMFS analyzed this alternative from the perspective of applying circle hook requirements to HMS-permitted vessels in billfish tournaments, and as such, the change in phrasing of the alternative has no impact on the analyses conducted herein. To reiterate, circle hook requirements implemented via this rulemaking would apply to Atlantic HMS permitted vessels, and vessels that should possess HMS permits, participating in Atlantic billfish tournaments and deploying natural baits or natural bait/artificial lure combinations.

The ecological impacts of alternative E3 would be similar to those identified under alternative E2, but would be somewhat reduced in scope. This alternative would reduce mortality in the directed billfish fishery by reducing post-release mortality. Under alternative E3, post-release mortality benefits would be primarily realized in the billfish tournament segment of the recreational fishery, but may also be realized outside of tournaments as anglers become comfortable and proficient with circle hooks and potentially increase their use voluntarily outside of tournaments. Voluntary use of circle hooks outside of tournaments may increase as a result of anglers wanting to maximize fishing experience with circle hooks to increase their expertise with the type of hooks that would be mandated in tournaments where they can win money. Further, many tournament anglers are viewed as leaders in the billfishing community and as they increase their use of circle hooks, non-tournament anglers may follow suit and increase their use as well. As such, based on RBS release data, this alternative would likely result in a decrease of white marlin post-release mortalities by approximately 23 percent over all, resulting in an estimated 303 (range: 141 – 508) fish released alive that would otherwise be expected to die, on average. There would likely be unquantified positive mortality benefits (decreased post-release mortality) for sailfish, blue marlin, tunas, sharks, and, to a lesser extent, swordfish as well other non-HMS species with which billfish tournament anglers interact (blackfin tuna, mahi-mahi, wahoo, etc.), resulting from improved hooking location and decreased damage to vital tissues. See alternative E1 and E2 for more complete discussions of the impacts of J-hooks and circle hooks on target and non-target species. The overall ecological impact of alternative E3 would be positive, but limited, given the relatively small contribution of U.S. anglers to total Atlantic-wide mortality. As such, alternative E3 would likely reduce, but not reverse current trends in Atlantic-wide fishing mortality rates for both blue or white marlin and possibly other species with which billfish tournament anglers interact. The United States will continue to encourage other ICCAT nations to implement circle hooks in their commercial and recreational fleets to reduce post-release mortality of billfish and other HMS. Based on the expectation that some anglers will continue to use J-hooks when targeting Atlantic blue marlin while participating in billfish tournaments, for the reasons described under alternative E2, the positive ecological benefits for blue marlin would likely be less than those anticipated for white marlin under alternative E3. As discussed under alternative E2, potential ecological benefits derived from the use of circle hooks may be undermined by angler actions including offsetting hooks, using non-traditionally shaped circle hooks (*i.e.* circle hooks in name only), and possibly increasing drop-back time.

NMFS received substantial comment supporting and opposing implementation of this preferred alternative. A prevalent theme contained in comments opposing mandatory circle hook use, in all or portions of the HMS and billfish recreational fisheries, was that the recreational sector has a minor impact on billfish populations relative to the commercial pelagic longline fleet. As discussed more fully in the analysis for alternative E2, data reported to ICCAT indicate that commercial fishing activities are responsible for the majority of Atlantic billfish mortality, from an international perspective (Kerstetter, 2006). However, from a domestic perspective a review of the data and two recent studies indicate that, in some years, the total mortality contribution of the domestic recreational billfish fishery may equal or exceed the total mortality contribution of the domestic pelagic longline fishery with regard to Atlantic white marlin. Please see the discussion of this issue under alternative E2 for additional details. These conclusions reinforce the appropriateness of implementing the preferred alternative to implement certain circle hook requirements in billfish tournaments to reduce recreationally induced fishing mortality.

Other comments opposing alternative E3 included suggestions that circle hook use should remain voluntary, that NMFS should allow J-hooks to be used for pursuing Atlantic blue marlin, that mandatory circle hook use in tournaments is not enforceable, and that mandatory circle hook use in tournaments may have large adverse economic impacts. Circle hook use has always been voluntary, and yet significant portions of the fishery continue to use J-hooks. Further, NMFS has actively been encouraging the use of circle hooks in HMS Fisheries since 1999. While there has been some progress in sectors of the fishery, anecdotal evidence suggests that substantial portions of the recreational fishery continue using J-hooks as the standard hook. Based on public comment from scoping and the Draft Consolidated HMS FMP, as well as an examination of post-release mortality data of blue marlin caught on J-hooks, this preferred alternative would allow anglers on HMS permitted vessels in billfish tournaments to continue to use J-hooks with artificial lures. This was clearly stated in the Draft Consolidated HMS FMP. NMFS believes that circle hook requirements in tournaments are enforceable, and public comment received during this rulemaking supports this. In addition to future agency efforts to enforce circle hooks, and the increasing use of tournament observers, NMFS believes that the conservation ethic of billfish anglers and the vested financial interests of billfish tournament participants in ensuring that all tournament participants compete fairly under the same rules and conditions, would result in significant self-enforcement of tournament circle hook requirements. NMFS has not seen evidence that participation in the fishery would decrease as a result of circle hook use or result in economic losses given that all tournaments would operate under the same set of regulations. Importantly, circle hooks have been shown to increase catch rates of some billfish species (Prince *et al.*, 2002), and are, on average, slightly less expensive than J-hooks. Many comments from both sides of the debate stated that circle hooks are effective at reducing mortality of Atlantic billfish. With the substantial conservation benefit associated with the use of circle hooks, recent information suggesting that the post-release mortality rate of Atlantic white marlin caught recreationally on J-hooks is substantially higher than previous estimates, data indicating that the mortality contribution of the recreational community toward Atlantic marlin may equal or exceed that of the domestic pelagic longline fishery in some years (see the discussion of alternative E2 for additional information), and the fact that circle hook requirements are already in place in the pelagic longline fishery, NMFS believes that mandatory circle use is an appropriate management action to implement at this time. Further, this alternative would strike an appropriate balance between achieving conservation goals and allowing the fishery to continue with a minimum of impacts or disruption.

Alternative E3 would not be expected to increase interactions with protected resources. NMFS has little or no data showing interactions between the directed Atlantic billfish fishery and protected species. NMFS' HMS Management Division has received one anecdotal report of such an interaction since late 2002**.** However, this alternative may contribute to a reduction of interactions as well potential mortalities associated with any such interactions based on the hooking mechanics, improved hooking location, and decreased damage of vital tissues generally associated with the use of circle hooks.

Alternative E4(a) would increase the minimum legal size for Atlantic white marlin to a specific size between 68 and 71 inches LJFL (172 – 180 cm) to reduce white marlin landings and the mortalities resulting from such landings. The current minimum size for white marlin is 66 inches LJFL (167 cm) and has been in place since 1998 (63 FR 14030). The aforementioned range was selected for analysis because, within a relatively small range of minimum sizes, potentially significant reductions in landings (25 – 82 percent) may be attained (Table 4.55). The minimum sizes analyzed represent the upper and lower limits of the sizes analyzed and do not represent a “slot limit” for white marlin. If E4(a) were preferred, a new specific minimum size would be implemented from within the range analyzed based on public comment, potential reductions in landings, the need to comply with ICCAT landing limitations, and other relevant factors. This alternative may also improve the likelihood of consistency with the ICCAT recreational marlin landings limit. In addition, management measures implemented prior to the 2007 ESA status review for white marlin, such as increasing the minimum size to reduce landings, would be relevant considerations during the deliberations of the status review team when they convene.

Alternative E4(b) would increase the minimum size for blue marlin to a specific size between 103 and 106 inches LJFL (261 – 269 cm) to reduce blue marlin landings and mortalities resulting from landings. The current minimum size for blue marlin is 99 inches LJFL (251 cm) and has been in place since 1998 (63 FR 14030). This range was selected for analysis because within this relatively small range of minimum sizes, significant reductions in landings (16-36 percent) could potentially be achieved (Table 4.55). The minimum sizes analyzed represent the upper and lower limits of the sizes analyzed and do not represent a “slot limit” for blue marlin. If E4(b) were to be implemented, a new specific minimum size would be implemented from within the range analyzed based on public comment, the potential reductions in fishing mortality given the overfished status of this species, the need to comply with ICCAT landing limitations, and other relevant factors. This alternative may improve the likelihood of consistency with the ICCAT recreational marlin landings limit.

Alternatives E4(a) and E4(b) would both likely have limited positive ecological impacts because increasing the minimum size would be expected to decrease landings by decreasing the pool of legal sized fish available for landing. The extent of these benefits would be dependent on fishing effort remaining relatively constant relative to current levels, as well as a continuation of the widespread practice of catch and release fishing for Atlantic billfish. In addition to potentially limiting known mortalities via reducing the number of fish landed, increasing the minimum sizes would also ensure that a larger proportion of the billfish population attain sexual maturity and that larger, more fecund, individuals retain the opportunity to spawn.

NMFS received public comments indicating both support and opposition to increasing the minimum size for blue and white marlin based on the rationale of allowing more white and blue marlin to reach sexual maturity, including, increasing the minimum size will force fishermen to target larger, more fecund females and that the Agency should consider a slot limit to protect these larger, more fecund, marlin. Generally speaking, the likelihood of landing a larger, more fecund female may increase by increasing the minimum size for blue marlin. For white marlin, however, there does not seem to be as strong of a correlation between length and age or fecundity as white marlin will first put on length, and then weight. Weight is generally an indicator of fecundity. However, most billfish fishermen tend to be opportunistic because the fisheries for blue and white marlin are characterized by extremely low catch per unit effort (CPUE) rates. These range from between 1.03 and 1.05 fish caught per hundred angler hours for white and blue marlin, respectively. Furthermore, most billfish caught are released. Tournament data between 1999 - 2004 indicate that, on average, only 8.1 and 1.8 percent of blue and white marlin, respectively, were landed. Increasing the minimum size would not likely result in fishermen targeting larger, more fecund females because of the opportunistic nature of this fishery and the fact that fishermen do not necessarily apply different techniques or attempt to "target" large versus small billfish.

NMFS received a comment asking what data were used to determine billfish size limits. These minimum sizes were selected to reduce the number of billfish that could be landed and to allow for female billfish to be protected from exploitation until after they have spawned. Furthermore, for blue and white marlin these minimum sizes were selected to achieve compliance with an ICCAT recommendation (97-09) adopted in 1997, requiring contracting parties to reduce billfish landings by at least 25 percent by 1999. Size distributions from Atlantic billfish tournaments held from 1995-1997 were used to analyze minimum size alternatives contained in the 1999 HMS FMP and to determine which minimum size corresponded with a 25 percent reduction in landings. NMFS wanted to implement a minimum size that allowed blue and white marlin to achieve the size and first maturity before potentially being removed from the population. It is estimated that the sizes at first maturity are approximately 89–90" LJFL for blue marlin and approximately 52" LJFL for white marlin, which are well below the current minimum sizes. RBS landings data for the period 1999 – 2004 was used for the size analysis contained in this document. Increasing the minimum size is not anticipated to have an effect on post- hooking mortality of released fish because the relationship between the size of a released fish and mortality is not known.

Table 4.55 shows the number of fish landed and cumulative proportion of total landings, providing potential landings reductions for each size with the corresponding ranges for blue and white marlin. Each minimum size within the range would provide unique reductions in landings and conservation benefits. Positive ecological impacts resulting from decreased landings of blue and white marlin increase as the minimum size is increased within the range analyzed. The actual reduction in landings and known mortalities would be dependent on the specific minimum size selected, and future fishing effort. Figure 4.21 and Figure 4.22 show the overall number of tournament landings, by size (inches, LJFL), for blue and white marlin for the years 1999 - 2004 combined.

Between 1999 and 2004, RBS data indicate that there were an average of 92 and 21 blue and white marlin that were landed above the current minimum sizes each year in tournaments, respectively. Under this alternative, the proposed minimum size increases of 68 - 71" LJFL and 103 - 106" for white and blue marlin, respectively, could potentially reduce landings by 25 - 67 percent for white marlin and 16 - 27 percent for blue marlin relative to current minimum sizes, based on historical data. This equates to approximately 15 - 25 blue marlin per year, on average, that might not be landed, should the Agency implement a legal minimum size between 103 - 106" LJFL. Further, under this alternative, a minimum size of 68 - 71" LJFL for white marlin could reduce landings by 6 - 14 fish during an average year. Landings in tournaments make up the majority of landings that are reported to ICCAT in compliance with Recommendation 00-13. In 2004, all but 3 of the 149 billfish reported to ICCAT were landed in tournaments. Some tournaments have a minimum size that is greater than the minimum size required by NMFS and do not allow the landing of billfish under a certain size that has already been landed in that tournament.

**Table 4.55 Cumulative number of white and blue marlin landed below each minimum size in tournaments from 1999-2004 between the current minimum size for blue (99") and white (66") marlin and the potential increased minimum sizes indicated. A minimum size would be selected between 68-71 inches for WHM and 103-106 for BUM.** Source: NMFS RBS Database.

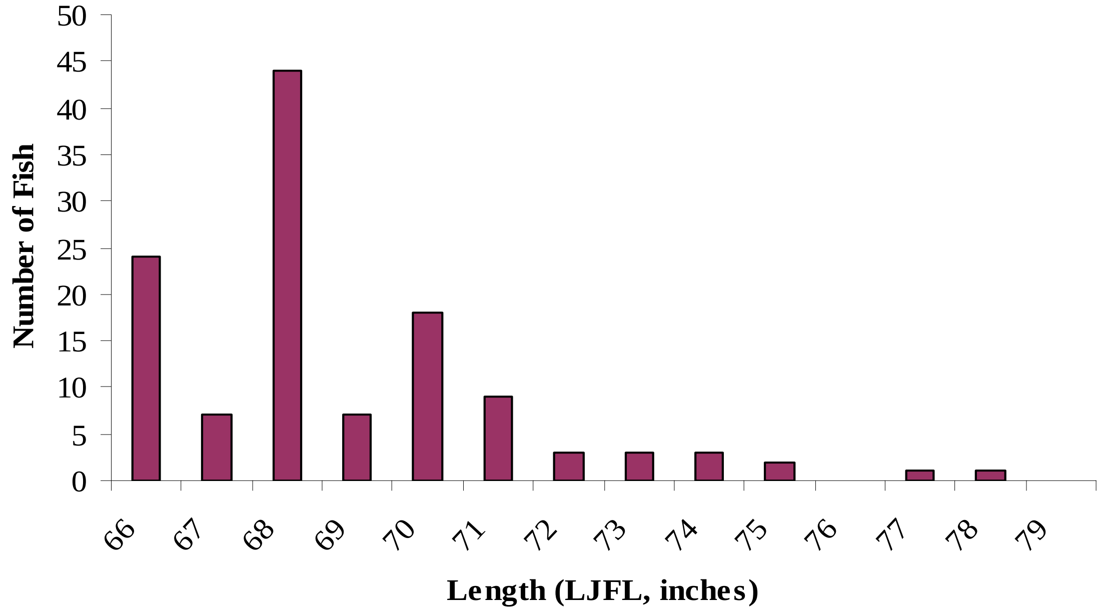

**Figure 4.22 Number of white marlin landed in tournaments between 1999-2004 by length (inches, LJFL).** Source: NMFS RBS Database.

Catch per unit effort (CPUE) data for blue and white marlin indicate that interactions with these species are a relatively rare event, ranging from 0.5 - 1.7 interactions per 100 hours of fishing between 1999 and 2004, as shown in Table 4.56. Mean CPUE per 100 hours for blue and white marlin during this time period were 1.05 and 1.03, respectively. The conservation benefits of a larger minimum size would be dependent, in part, on fishing effort and practices remaining relatively constant. If fishing effort were to increase significantly, the number of landings could also increase, despite increases to the minimum size. Interactions would likely also increase with increased effort, which would likely increase the number of post-release mortalities of billfish and other species.

**Table 4.56 Catch per unit effort and numbers of blue and white marlin kept and released 1999-2004.** Source: Billfish Tournament Database, Southeast Fisheries Science Center.

| Year | Blue Marlin | | | White Marlin | | | Sailfish | | |
|---|---|---|---|---|---|---|---|---|---|
| | Kept | Released Alive | CPUE/ 100 hours | Kept | Released Alive | CPUE/ 100 hours | Kept | Released Alive | CPUE/ 100 hours |
| **1999** | 172 | 1527 | 1.4 | 36 | 1456 | 1.3 | 30 | 1907 | 1.6 |
| **2000** | 117 | 1467 | 1.1 | 8 | 975 | 0.7 | 18 | 2198 | 1.5 |
| **2001** | 75 | 1038 | 0.9 | 22 | 1306 | 1.0 | 11 | 3073 | 2.4 |
| **2002** | 84 | 1132 | 0.9 | 33 | 2207 | 1.7 | 14 | 3117 | 2.3 |
| **2003** | 96 | 1133 | 0.9 | 20 | 614 | 0.5 | 24 | 4171 | 3.0 |
| **2004** | 110 | 1538 | 1.1 | 25 | 1349 | 1.0 | 9 | 4467 | 3.2 |

Alternatives E4a and E4b are aimed at reducing landings and mortalities that result from landings for billfish, however, fishing mortality of released fish would continue to occur as a result of physical stress and fatigue, hook induced trauma, and physical damage to the gills, esophagus, and/or stomach even if a fish is not landed. Mortality reductions associated with these alternatives would likely be limited, based on the relatively small decrease in the number of fish landed as a result of an increased minimum size as well as the continuation of post-release mortalities. As discussed under alternative E1, minimum sizes do not directly impact the level of post-release mortality. Given the post-release mortality benefits of circle hooks, circle hook requirements (alternative E2 or E3) in combination with this alternative could increase the ecological benefits by reducing post-release mortalities and landings. In an attempt to reduce post hooking mortality of all billfish, NMFS is selecting alternative E3, limiting all HMS permitted anglers to the use of circle hooks when using live bait and participating in tournaments that have a prize category for billfish, as a preferred alternative. For a more detailed discussion of the merits of circle hook use compared to J hooks, see alternatives E1 through E3 above.

While NMFS cannot predict angler behavior, under alternatives E4a and E4b, anglers may choose to reduce effort if they believe that they would be unable to land a marlin given increased minimum sizes. This could result in unquantified positive ecological impacts for Atlantic billfish, other HMS, and non-HMS species with which recreational billfish fishermen interact. These potential impacts would be dependent upon significant shifts in fishing effort to other non-billfish species. If billfish effort were shifted to other species, this reaction could have negative ecological impacts on tunas, swordfish, sailfish, spearfish, sharks, and other species typically interacted with, or targeted by Atlantic billfish fishermen if effort shifts to other fisheries. As mentioned, it is not possible to predict angler response to increased minimum sizes, so the effects are uncertain. This alternative is not anticipated to increase interactions with protected species.

NMFS received several comments in support of increasing the minimum size for blue and white marlin for a variety of reasons, including: compliance with the ICCAT 250 fish limit; reducing the number of billfish that are landed on an annual basis to minimize fishing mortality on these overfished stocks; and, allowing larger more fecund billfish to spawn again by having a larger minimum size in place. NMFS acknowledges that, based on the number of marlin reported as landed to the Agency, the United States is regularly and substantially below the annual ICCAT marlin landings limit and that allowing more fecund fish (generally older, larger, and heavier fish) to spawn may benefit the populations. Nevertheless, there is a limited conservation benefit associated with this alternative given the current small number of landings that are reported on an annual basis. Furthermore, alternative E6, a preferred alternative, would implement an increase in the minimum size and possibly implement catch and release marlin fishing, as necessary, to maintain compliance with the ICCAT landings limit.

NMFS also received numerous comments opposing an increase in the minimum size for blue and white marlin. General themes contained within these comments included: many tournaments already have minimum sizes larger than the current legal minimum size; white marlin weight and length are not closely correlated for fish above 62" LJFL; circle hook requirements will provide equal or greater ecological benefit than an increased minimum size, and the fact that the United States is substantially below the ICCAT marlin landings limit on a regular basis.

These alternatives were not preferred in the Draft Consolidated HMS FMP, and no new information has been received to alter the Agency's previous decision. As such, the Agency does not prefer alternatives E4(a) and E4(b) in the Final Consolidated HMS FMP, at this time. Other alternatives analyzed in this Final Consolidated HMS FMP would likely achieve the objectives of the rulemaking, however, the Agency may consider minimum size increases in future rulemakings, as necessary and appropriate.

Alternative E5 would implement a recreational bag limit of one Atlantic billfish per vessel per trip. No more than one Atlantic billfish would be allowed to be possessed, retained, or landed on, or by, a vessel regardless of the length of the trip. Alternative E5 would likely have minimal positive ecological impacts. As discussed in the analysis for alternative E4, billfish fisheries have some of the lowest CPUE estimates of any recreational fishery. In 2003, there were 149,412 tournament hours of fishing resulting in 7,926 billfish being caught, or 0.024 billfish caught per angling hour. Fisher and Ditton (1992) found that billfish anglers reported an average of 13 trips/year, ranging from 8.7 - 17.3 depending on the region. On average, each angler landed less than one (0.7) billfish per year, or approximately 1 billfish every 1.4 years. Data collected during the same survey found that only 11 percent of billfish caught during respondents' last tournament were landed (Fisher and Ditton, 1992). NMFS is aware that some anglers continue to land multiple billfish on a single trip, however the Agency has little data on how frequently this occurs. Anecdotal information suggests that this is a rarity for marlins, and may occur more frequently with sailfish. In the 2005 calendar year, there were four fishing trips, as reported to NMFS, that were known to have landed more than a single sailfish. Based on the overall rarity of catching an Atlantic billfish that meets the minimum size requirements, implementing a bag limit of one fish per vessel per trip would have minimal ecological benefits. However, alternative E5 would provide additional protection to these species, which are considered overfished with overfishing still occurring. As with alternative E4, efforts to reduce billfish landings should be considered concurrently with other alternatives that may reduce the post-hooking mortality of billfish via the use of alternatives to J-hooks that reduce the risk of hooks becoming deeply ingested by billfish (alternatives E2 and E3). If anglers shifted effort to other non-billfish species as a result of the implementation of a bag limit, it could adversely impact these species to some unquantifiable extent.

Sailfish are often found closer to shore and travel in schools during winter months. Therefore, the likelihood of anglers catching multiple fish during excursions, especially in areas off the Florida Keys and Southeastern Florida, is increased. Trips landing multiple sailfish were reported to NMFS in 2005, as noted above, however, there are no reports outside of tournaments of vessels landing multiple Atlantic white or blue marlin during a single trip. Nevertheless, information obtained from a brief survey of internet websites (2005) indicates that billfish anglers have retained as many as nine billfish (sailfish) in a single trip. The CPUE for sailfish landed in tournaments between 1999 - 2004 ranged from 1.5 - 3.2 fish per 100 hours fishing, significantly greater than for blue or white marlin. Sailfish were determined to be overfished in 1998. The 2001 stock assessment for sailfish did not estimate MSY or the fishing mortality rate, so it is difficult to discern the exact status of sailfish at this time. Multiple ICCAT resolutions and recommendations advise that Contracting Parties should consider methods to reduce fishing mortality rates for Atlantic billfish. Implementation of a bag limit of one billfish per vessel per trip would be consistent with this objective by potentially reducing landings and mortalities of Atlantic billfish with attendant positive ecological impacts.

NMFS received comments in support of alternative E5 (bag limit of one billfish/vessel/day) stating that with strict landing limit under which the United States is operating (250 Atlantic blue and white marlin combined), that it would be inappropriate to let one boat come back with more than a single fish on any given day. Given that recent landings of Atlantic blue and white marlin have been substantially below the 250 marlin limit, this issue has not been identified as a major problem to date. However, should it become an issue, the Agency may revisit the issue of bag limits for this or any other appropriate reason. The Agency also received several comments opposing this alternative for various reasons, including that (in the words of commenters): it would encourage the culling of fish [thereby possibly increasing dead discards]; landing a few fish is not the issue; and, a bag limit will not reduce post-release mortality of billfish unless careful handling and release guidelines are followed.

Overall, implementing a bag limit of one Atlantic billfish per vessel per trip is not expected to have substantial positive ecological impacts because multi-billfish excursions, especially for blue and white marlin, are rare events. However, if a multi-fish trip did occur, a bag limit may prevent excessive landings on these exceptional excursions. Data suggest that because of the extremely low catch rates that characterize the billfish fishery, implementing a bag limit may have limited positive ecological impacts. Alternative E5, was not a preferred alternative in the Draft Consolidated HMS FMP, and no new information has been received to alter the Agency's previous decision. As such, NMFS does not prefer alternative E5 in the Final Consolidated HMS FMP, at this time. Other alternatives analyzed in the Consolidated HMS FMP would likely achieve the objectives of the rulemaking, however, the Agency may consider bag limits in future rulemakings, as necessary and appropriate.

Alternative E6, a preferred alternative, would allow NMFS to implement ICCAT recommendations pertaining to recreational marlin landing limits. Alternative E6 would establish an in-season adjustment framework to implement ICCAT marlin landing limits, allow for in-season changes to minimum sizes, and provide the Agency with the ability to shift the billfish fishery to catch and release only for Atlantic marlin, if necessary, to ensure compliance with ICCAT recommended landing limits. As noted earlier, the United States is currently limited to landing 250 recreationally caught Atlantic blue and white marlin, combined. This landing limit may change in the future as a result of future ICCAT recommendations.

As a contracting party to ICCAT, the United States negotiates with other contracting parties to agree upon binding, conservation and management recommendations. Domestically, the Atlantic Tunas Convention Act authorizes the promulgation of regulations as may be necessary and appropriate to implement binding recommendations adopted by ICCAT. This preferred alternative would directly implement ICCAT recommendation 00-13 and subsequent recommendations modifying 00-13.

To provide for maximum utilization of the U.S. recreational Atlantic marlin landing limit without exceeding it, this alternative would allow NMFS to increase the legal minimum size of blue and/or white marlin, as appropriate. The anticipated effect of an in-season minimum size increase would be to slow landings, if necessary, and thereby reduce the probability of having to shift to catch and release fishing only for Atlantic marlins. The ability to increase minimum size limits in-season is intended to minimize potential disruptions in the fishery, by avoiding more dramatic regulatory action requiring catch and release only fishing. Under this alternative, the size range that would be made available to NMFS for in-season management actions is from 117 to 138 inches for Atlantic blue marlin and 70 to 79 inches for Atlantic white marlin. These size ranges differ substantially from those analyzed under alternatives E4(a) and (b). The size ranges selected for analysis under this alternative were intended to ensure compliance with the ICCAT landing limit and would only be implemented if necessary, and once certain thresholds for action (discussed below) were reached. They were selected to minimize the potential for further in-season disruptions to the fishery, such as a requirement to shift to catch and release only fishing. The potential legal minimum size ranges under alternatives E4(a) and (b) were analyzed for general year round implementation as a means to reduce overall landings and mortalities.

The need for action and the specific minimum size temporarily implemented would be based upon a review of landings, time remaining until conclusion of the current fishing year, current and historical landings trends, and any other relevant factors. As a backstop to ensure that U.S. actions remain consistent with the ICCAT landing limit, the fishery would become catch and release only for the remainder of a fishing year if the landing limit was achieved. If marlin minimum sizes were increased to slow landings during a given fishing year, they would revert back to the previous minimum size at the start of the next fishing season.

Consistent with ICCAT recommendations, NMFS would automatically subtract any overharvest from the subsequent fishing year's landing limit, and may carry forward underharvest to the subsequent fishing year. To increase or decrease the annual 250 marlin landings limit as a result of carrying forward future over or underharvest of Atlantic marlins the Agency will publish a notice in the Federal Register. To increase or decrease the 250 marlin recreational landing limit as a result of a new ICCAT recommendation, would require rulemaking under this preferred alternative. NMFS received comment recommending that the Agency automatically carry forward any underharvest to the following management period. As noted above, this alternative allows for carry-forward of underharvest to occur. However, given the uncertainty surrounding landings of Atlantic marlin in the Commonwealth of Puerto Rico and the U.S. Caribbean, the United States has made a commitment not to carry forward underharvest until such time as this uncertainty is resolved.

Alternative E6 would likely have minor positive ecological benefits if implemented on its own. This conclusion holds true whether examined under the existing June 1 – May 31 fishing year management scenario or under the preferred alterative (alternative G2) to shift billfish management to a calendar year management cycle (January 1 – December 31) management cycle. This alternative could reduce mortalities of Atlantic billfish by reducing the mortality associated with landings. The U.S. landings (inclusive of dead discards) of Atlantic blue and white marlin averaged 2.4 percent and 4.5 percent (respectively) of aggregate Atlantic-wide landings for these species, as reported to ICCAT for the period 1999 - 2004. The total contribution of the U.S. recreational fleet to aggregate Atlantic-wide marlin mortality has not been definitively quantified, but may be larger than previously estimated based on new post-release mortality estimates for white marlin, as discussed under the analyses for alternatives E2 and E3. Since ICCAT adopted the recommendation containing the U.S. recreational limit in 2001, reported U.S. recreational marlin landings have ranged from a high of 279 in 2002 to a low of 136 in 2003, averaging 189 fish per annum. Details can be seen in Table 4.48.

Based on known landings, the ecological benefits of this alternative are likely limited given that during the period 2001 through 2004, the United States has averaged 189 recreationally landed marlins, or approximately 75 percent of the landing limit each year, and that in two of those four years, the United States was more than 100 marlin, or the equivalent of 40 percent, below the U.S. landing limit. However, the relative benefits of this alternative could increase if recreational landings increased substantially. NMFS received comment on the limited ecological impact of this alternative that was categorized into two opposing views and which suggested two different courses of action. Some commenters suggested that the limited ecological impact was not worth any potential adverse economic impact, even a very limited one, while other commenters suggested that the United States must implement the 250 marlin limit to live up to U.S. international obligations and as part of a strategy to implement appropriate measures to help limit billfish mortality. Implementation of this preferred alternative is anticipated to allow the United States to continue to successfully pursue international marlin conservation measures by fully implementing U.S. international obligations and potentially provide minor ecological impacts.

Alternative E6 may prevent future landings in excess of the ICCAT landing limit, and therefore may prevent future increases in mortalities associated with known landings. Again, this statement holds true for either the Fishing Year or Calendar Year management cycle. However, because a landing limit cannot directly control effort or post-release mortality, this alternative cannot directly control fishing mortality, which may increase or decrease with changing effort and fishing practices despite domestic implementation of the ICCAT landing limit. This alternative is not anticipated to have any impact on interactions with protected resources or impact other non-billfish species, but cannot prevent such changes if fishing effort changes to other species. Alternative E6 may result in limited impacts on the landings, discards, and interactions with other HMS, and other finfish species such as dolphin fish, king mackerel, and wahoo that are frequently encountered by HMS fishermen. Positive or negative ecological impacts may occur for these species, and would depend on whether or not the threshold for management action is achieved and subsequent angler response. However, no impacts are anticipated in the near future because, based on the current marlin accounting methodology used for compliance purposes and the widespread practice of catch and release fishing for billfish (75 to 99 percent), it seems unlikely that the threshold for action would be reached. Nevertheless, as noted above, the likelihood of achieving the threshold for action could change with changes in effort, compliance with reporting requirements, or improved accuracy of accounting methodologies.

Under both the Calendar Year or Fishing Year management cycles, alternative E6 may provide minor positive ecological benefits if minimum size increases or catch and release only fishing requirements were implemented for Atlantic blue and white marlin as a result of the threshold for management action being achieved under this alternative. Impacts on non-billfish species, in terms of landings and post-release mortality may remain the same, increase, or decrease depending on angler response to increased minimum sizes and/or a shift to catch and release only fishing. Given the widespread practice of catch and release fishing for billfish, as discussed in detail under alternative E1, it is likely that most billfish anglers would continue to expend effort fishing for Atlantic marlins, which would result in some level of landings and continuing post-release mortalities under increased minimum sizes or a shift to a catch and release only fishery. Assuming no change in effort or angler behavior given current catch and release rates in the fishery, there would likely be little change in the ecological impacts from the status quo. Alternatively, anglers may reduce effort if they believe that they would be unable to land a billfish given a minimum size increase, or would be prohibited from landing a marlin given a landings prohibition. This could result in unquantifiable ecological benefits for Atlantic billfish, other HMS, and non-HMS species with which recreational billfish fishermen interact. Further, it is also possible that anglers may shift effort to other non-marlin species. This response could increase negative ecological impacts on tunas, swordfish, sailfish, spearfish, sharks, and other species with which Atlantic billfish fishermen typically interact. In conjunction with alternative E3, alternative E6 could expand ecological benefits to Atlantic billfish by reducing post-release mortality and limiting mortalities associated with landings to levels consistent with ICCAT landing limits. Further, the United States may benefit from increased negotiating leverage at ICCAT, and thus allow for more rapid development and implementation of additional international management measures, as deemed appropriate by ICCAT. Positive ecological benefits, specifically reducing fishing mortality, would be relevant considerations in the anticipated 2007 ESA Status Listing Review for white marlin.

Alternative E7 was a preferred alternative in the Draft Consolidated HMS FMP; however, it is not preferred in the Final Consolidated HMS FMP. This alternative would allow only catch and release fishing for Atlantic white marlin effective January 1, 2007 through December 31, 2011. Possession and retention of Atlantic white marlin would be prohibited at all times and under all circumstances by all U.S. flagged vessels. This provision would expire five years from the effective date unless specifically extended by NMFS.

The ecological impacts of eliminating recreational landings of white marlin can be estimated from U.S. landings reported to ICCAT, as well as other domestic fisheries surveys. Alternative E7 would reduce mortalities of white marlin by eliminating mortalities associated with landings. The reported U.S. white marlin landings for 2001 - 2004 can be seen in Table 4.48. In 2001, 2002, 2003, and 2004, there were 116, 88, 23, and 31, respectively, white marlin reported landed in the U.S. Atlantic billfish fishery. The 2004 billfish landings reported to ICCAT were based on tournament reports and MRFSS intercepts. Because non-compliance with many reporting requirements is known to be occuring, NMFS considers all billfish self-reported statistics to be minimum estimates with an unquantified bias toward low estimates. Fishing surveys, such as MRFSS and the LPS, discussed above, provide additional data useful for estimating landings of Atlantic billfish (Table 4.50 and Table 4.51). The MRFSS survey includes HMS, however, it was not designed for these species, which are considered “rare event” species as compared to other recreationally caught species. The LPS survey was designed to intercept HMS fisheries, but because it does not operate in all Atlantic coastal states and operates for only a portion of the year, it is only a subset of aggregate U.S Atlantic landings. The recent

LPS white marlin landings estimates are in some instances substantially lower, and in other instances substantially higher, than those tabulated directly from observed landings. This is a result of extrapolating landings from survey intercepts. A more complete discussion of landings databases is provided in the analysis of alternative E1. For the years 1999 through 2004, the LPS estimated landings of white marlin were six, four, four, 218, 365, and 78, respectively. Additionally, as discussed above, the United States is currently limited to 250 blue and white marlin landings (combined) annually by ICCAT. This recommendation was adopted in 2000 and entered into force in 2001.

Alternative E7 would likely provide limited ecological benefits to Atlantic-wide white marlin stocks by itself, given the limited number of landings. Under this alternative, a large portion of the fish currently landed would likely be conserved, however estimates vary. Table 4.48 through Table 4.50 provides the potential range of mortality reductions that could be achieved if alternative E7 was implemented. Impacts on other species with which HMS fishermen typically interact would depend on angler response to a catch and release fishery for white marlin. Anglers are likely to respond in three ways: 1) no change in effort or target species; 2) decreased effort; and, 3) shift target species. If angler behavior does not change to any appreciable extent, NMFS anticipates that the impacts would be similar to those as discussed under alternative E1. If anglers respond by decreasing effort, alternative E7 could result in positive ecological impacts for HMS and other species by potentially reducing landings and interactions, which could reduce post-release mortality. If anglers respond by shifting effort to other target species, such as sailfish, blue marlin, dolphin, and wahoo, this alternative may result in increased landings and interactions with these and other species. NMFS received public comment indicating that if white marlin landings were prohibited, tournaments and fishermen would likely increase fishing effort on blue marlin. Data are unavailable to allow quantification of these impacts, nevertheless, any one or any combination of the aforementioned responses and their attendant impacts are possible. However, as stated above, the impacts are likely to be limited given current angler ethics as demonstrated by high levels of participation in catch and release fishing, as shown in Table 4.49, Table 4.50, and Table 4.51, which range from 75.8 to 99.4 percent.

Alternative E7 cannot, by itself, reduce post-release mortalities of white marlin. As such, all mortality gains would be expected to occur through the reduction in landings. However, as discussed in the Draft Consolidated HMS FMP, alternative E7, if used in conjunction with alternative E3 (mandatory use of circle hooks in billfish tournaments), could substantially expand possible ecological benefits by reducing landings to zero and considerably reducing the post-release mortality of recreationally captured white marlin. If alternatives E7 and E3 were selected and proven effective, the United States may also benefit from an improved negotiating position at ICCAT. Positive ecological gains, specifically reducing fishing mortality, would also be relevant considerations during the anticipated 2007 ESA Status Listing Review for white marlin.

NMFS received strong public comment opposed to the Atlantic white marlin catch and release alternative. Based on public comment that indicated more significant concerns over potential adverse economic impacts to the fishery if catch and release only fishing for Atlantic white marlin were required, as well as a number of other factors, including but not limited to, the impending receipt of a new stock assessment for Atlantic white marlin and upcoming international negotiations on Atlantic marlin, NMFS is not preferring to prohibit landings of Atlantic white marlin at this time. Additionally, the Agency received substantial comment in support of this measure. The commenters supporting the landings prohibition stated concerns over white marlin stock status, the ESA listing review, and an interest in maintaining leadership at the international level. The implementation of circle hook requirements (alternative E3) would be an important first step in reducing mortality in the directed billfish fishery. NMFS will consider catch and release only fishing options for Atlantic white marlin as well as other billfish conservation measures in future rulemakings, as necessary and appropriate.

Alternative E8 would allow catch and release only fishing for Atlantic blue marlin effective January 1, 2007. This provision would sunset five years from date of implementation unless specifically extended by NMFS. This alternative would prohibit the possession, retention, and landing of Atlantic blue marlin at all times and under all circumstances by all U.S.-flagged vessels. The ecological benefits of eliminating recreational landings of blue marlin can be estimated from U.S. landings reported to ICCAT, as well as other domestic fisheries surveys. The reported U.S. blue marlin landings for 2001 - 2004 can be seen in Table 4.48. In 2001, 2002, 2003, and 2004, there were 77, 191, 113, and 118 respectively, blue marlin reported landed in the U.S. Atlantic billfish fishery. As discussed above, in 2004, billfish landings reported to ICCAT were based on tournament reports and MRFSS intercepts. Because non-compliance with many reporting requirements is known to occur, NMFS considers all billfish self-reported statistics to be minimum estimates with an unquantified bias toward low estimates. Fishing surveys, such as MRFSS and the LPS, discussed above, provide additional data useful for estimating landings of Atlantic billfish (Table 4.50 and Table 4.51). The recent LPS blue marlin landings estimates are lower than those calculated directly from observed landings. For the years 1999 through 2004, the LPS estimated landings of blue marlin were three, zero, zero, zero, 101, and 45, respectively. Additionally, as discussed above, the United States is currently limited to 250 blue and white marlin landings (combined) annually by ICCAT.

Alternative E8 would likely provide some ecological benefits to blue marlin stocks, however, with the ICCAT marlin landings limit and the currently low recreational landings rate for the species, NMFS believes this alternative would likely provide limited ecological benefits. Alternative E8 would reduce mortalities of blue marlin by eliminating mortalities associated with landings. Under this alternative, a large portion of the fish currently landed would likely be conserved, however estimates vary. Alternative E8 cannot, by itself, reduce post-release mortalities of Atlantic blue marlin. As such, all mortality gains would likely occur through the reduction in landings.

As with alternative E7, impacts on other species with which HMS fishermen typically interact would depend on angler response to a catch and release fishery for blue marlin. Anglers are likely to respond in three ways: (1) no change in effort or target species; (2) decreased effort; and, (3) shift target species. If angler behavior does not change to any appreciable extent, NMFS anticipates that the impacts would be similar to those as discussed under alternative E1. If anglers respond by decreasing effort, alternative E8 could result in positive ecological impacts for HMS and other species by potentially reducing landings and interactions, which could reduce post-release mortality. If anglers respond by shifting effort to other target species, such as sailfish, white marlin, dolphin, and wahoo, this alternative may result in increased landings and interactions with these and other species. Data are unavailable to allow quantification of these impacts, however, any one or any combination of the aforementioned responses and their attendant impacts are likely. However, as stated above, the impacts are likely to be limited given current angler ethics as demonstrated by high levels of participation in catch and release fishing, as shown in Table 4.49, Table 4.50, and Table 4.51, which range from 75.8 to 99.4 percent.

Additionally, as discussed in the Draft Consolidated HMS FMP, this alternative, if used in conjunction with alternative E3 (mandatory use of circle hooks in billfish tournaments), could maximize the ecological benefits by reducing landings to zero and substantially reducing the post-release mortality of recreationally captured blue marlin. If alternatives E8 and E3 were selected and proven effective, the United States may benefit from an improved negotiating position at ICCAT.

This alternative was analyzed but not preferred in the Draft Consolidated HMS FMP or Final Consolidated HMS FMP due to potentially substantial negative social and economic impacts, public comment, and other reasons. Nevertheless, the Agency may consider catch and release only options for Atlantic blue marlin as well as other billfish conservation measures in future rulemakings, as necessary and appropriate. The United States will continue its efforts to reduce billfish mortality both domestically and at the international level. NMFS has preferred an alternative that would fully implement U.S. international obligations as per ICCAT Recommendation 00-13 and subsequent amendments to it. Additionally, the Agency has alternative E3, which would require the use of non-offset circle hooks in Atlantic billfish tournaments by HMS permitted vessels when deploying natural bait or natural bait/artificial lure combinations, to reduce post release mortality of billfish stocks.

*Social and Economic Impacts*

Alternative E1, the No Action alternative would likely have no adverse short-term economic impacts. Ditton and Stoll (2003) conservatively estimate the aggregate economic impact of billfish fishing trips in the U.S. Atlantic to be $22.7 million annually, not including Puerto Rico. Please see Section 3.5.2 for additional discussion of the economic status of the directed billfish fishery.

As of February 1, 2006, there were 25,238 HMS Angling category permits, 4,173 CHB category permit holders, and 4,824 General category permits which represent the number of vessels that are legally authorized to participate in the Atlantic billfish fishery. General category permit holders are eligible to fish for, retain, or posses, Atlantic billfish only when participating in a registered HMS tournament. The number of Angling category permit holders, and possibly the number of CHB category permit holders, is thought to be considerably below the number of vessels that should be permitted. See Section 3.9 of this document for additional detail regarding permitting issues. Further, because HMS Angling, CHB, and General category permits are vessel permits and any given vessel could have multiple anglers on board, the number of vessel permits underestimates the actual number of fishery participants. Given the multi-species nature of HMS Angling and CHB permits, and the fact that vessels are permitted rather than individual anglers, NMFS does not have the ability to identify what subset of these permitted vessels, or how many anglers, engage in billfishing based on the best scientific information available.

Ditton and Stoll (2003) estimated that there are 7,915 billfish anglers in the U.S. Atlantic and 1,627 billfish anglers in Puerto Rico.

Alternative E1 would likely result in a continuation of the fishery consistent with current operating patterns. It would not be expected to alter participation rates of private anglers, demand for CHB trips, or to impact participation in billfish tournaments. Alternative E1 would not likely result in any change or redistribution of fishing effort in the short-term or impact hook manufactures, retailers, or other small businesses associated with the recreational billfish fishery.

Alternative E2 would likely have limited adverse social and economic impacts. As discussed in Section 3.9.4, there were 25,238 HMS Angling category permits, 4,173 CHB category permit holders, and 4,824 General category permits as of February 1, 2006. This represents the universe of vessels that could be impacted by circle hook requirements under alternative E2. However, given that these are vessel permits, it is not possible to quantify the number of individual fishermen participating in HMS Fisheries who may be impacted by circle hook requirements.

Hooks employed by recreational anglers while pursuing HMS typically range in size from 5/0 to 14/0 for J-hooks and 7/0 to 20/0 for circle hooks. A limited survey of hook prices (Summer 2005) indicated that J-hooks of the sizes and styles used by HMS recreational fishermen ranged in price from a low of $0.50 to a high of $7.50 each, with an average price of $2.70. Similarly, circle hooks of the sizes and styles used by HMS recreational fishermen ranged in price from a low of $0.30 to a high of $7.00 each, with an average price of $2.24. A comparison of the two indicates that anglers could, on average, save approximately $0.46 for every circle hook purchased for use in place of a J-hook, if mandatory circle hook requirements were implemented in HMS fisheries. As such, initial purchases of circle hooks to comply with circle hook requirements would represent a minor economic cost, however, over the long-term, circle hook requirements associated with this alternative may result in a minor economic benefits, assuming the price differential between circle and J-hooks remains stable. Nevertheless, the purchase of hooks represents only a minor capital expenditure relative to other costs associated with participating in this fishery, including purchasing, equipping, maintaining, and running of vessels, which can run into the hundreds of thousands of dollars or more. As such, any potential economic impacts, either positive or negative, stemming from the purchase hooks are likely to be *de minimus* in nature. As previously discussed, NMFS cannot quantify the number of impacted anglers. Further, the quantity of hooks purchased by individual anglers varies widely from the occasional angler to those who fish regularly, and as a result of these factors, NMFS cannot estimate an aggregate economic cost. The delay in implementation of circle hook requirements, specifically requested by HMS and Billfish Advisory Panel members and the public, would be anticipated to allow hook manufacturers, retailers, and anglers adequate time to utilize current inventories and alter production rates of J-hooks, thereby minimizing any potential adverse economic impacts associated with alternative E2.

Alternative E2 may result in a temporary decrease in angler consumer surplus given anticipated or real loss of fish as fishermen adjust to and become more proficient with the use of circle hooks. However, Prince *et al*. (2002) found that circle hooks were actually 1.83 times more likely to hook a sailfish than a J-hook, and that once hooked, the catch percentage was virtually identical for each type of terminal gear. Skomal *et al*. (2002) reported similar findings with bluefin tuna, stating that catching success was similar for the two hook types. Skomal *et al*. found that 68 percent of recorded J-hook bites and 74 percent of circle hook bites resulted in landed tuna. Taken in combination, data from these studies suggest that there could potentially be an increase in angler consumer surplus as a result of increased catches, and that any loss of angler consumer surplus may be due to a perceived loss of fish, as opposed to a real loss of fish. However, the true effect of circle hooks on catch rates is not known for other HMS species. Any reduction of angler consumer surplus could be mitigated to an extent by the ability of anglers to continue to utilize J-hooks with artificial lures under alternative E2. In addition, the phase-in period associated with this alternative would allow anglers time to become comfortable and proficient with circle hook use prior to mandatory implementation, further mitigating any potential loss of angler consumer surplus. NMFS received public comment voicing concern that circle hooks may decrease catches of some HMS or non-highly migratory species. The Northeast Distant Statistical Area (NED) Circle Hooks study shows that deployment of circle hooks in the commercial pelagic longline fishery can result in a decrease in the number of swordfish caught under some oceanographic conditions, however, NMFS has only limited data on the impact of circle hooks in the recreational swordfish fishery or other recreationally caught non-HMS species and potential socio-economic effects. NMFS is aware of these concerns and will examine this issue as data becomes available.

Impacts on tournaments would likely be minimal, given the increase in the number of tournaments that provide special award categories or additional points for billfish captured and released on circle hooks. However, it is possible that there could be a decrease in tournament participation and demand for CHB trips, as well as trips taken by individual anglers based on real or perceived declines in catch under this alternative. NMFS cannot predict angler behavior with regard to participation in tournaments, demand for CHB trips, or trips taken by individual anglers in reaction to potential circle hook requirements. As such, if any tournaments are cancelled, demand for CHB trips decreases, or trips taken by individual anglers decline as a result of circle hook requirements, there could be some unquantified economic costs depending on the size of the tournament or the number of CHB trips or individual angling trips that are not taken.

While there may be an initial decrease in angler consumer surplus, alternative E2 may provide long-term positive benefits with regard to increased angler consumer surplus and willingness to pay if circle hooks contribute to rebuilding efforts and result in increased encounter rates. However, given the limited contribution of U.S. fishermen to aggregate Atlantic-wide catches of billfish, the Atlantic-wide benefits to billfish populations of alternative E2 may be limited. This alternative may enhance the United States' negotiating position at ICCAT by demonstrating the United States' commitment to the conservation of recreationally caught HMS at a time when other ICCAT nations are beginning to determine the extent of their domestic recreational fisheries. Improved negotiating position at ICCAT may allow for the more rapid implementation of recreational circle hook requirements Atlantic-wide. Alternative E2 may be difficult to enforce given the ability of anglers to possess both circle and J-hooks onboard at the same time.

The economic and social costs and benefits of alternative E3, a preferred alternative, are anticipated to be similar to, but reduced from the estimated impacts discussed under alternative

E2. As discussed more fully under the ecological analysis for this alternative, NMFS has made a slight technical adjustment in the phrasing of alternative E3 in this Final Consolidated HMS FMP to clarify the universe of affected anglers. NMFS analyzed this alternative from the perspective of applying non-offset circle hook requirements to HMS-permitted vessels in billfish tournaments in the Draft and Final Consolidated HMS FMP, and as such the change in phrasing of the alternative has no impact on the analyses conducted herein.

NMFS also received comment during scoping and the public comment period for the Draft Consolidated HMS FMP that tournament operators would need advance notice of impending circle hook regulations to allow for changes in the production of rules and advertising, and to inform tournament participants of potential circle hook requirements. Given the severe impacts of the 2005 hurricane season, NMFS substantially extended the public comment period and delayed the anticipated publication date of the Final Consolidated HMS FMP. In the meantime, NMFS surveyed a number of tournament operators in the Atlantic, Gulf of Mexico and Caribbean to better understand various aspects of tournament operations. NMFS determined that a delayed date of effectiveness of between four and six months would likely provide adequate time for tournament operators and participants to adjust tournament rules, formats, and advertising, as necessary, as well as to notify anglers of changes, and allow anglers to adjust fishing practices and take other steps appropriate to minimize any potential costs created by a shift to non-offset circle hooks in billfish tournaments. As such, given the anticipated publication date for the Final Consolidated HMS FMP of July 2006, and the anticipated publication date for the Final Rule of August 2006, NMFS prefers to maintain the effective date of January 1, 2007, for preferred alternative E3. This effective date is consistent with the effective date for preferred alternative E3 as contained in the Draft Consolidated HMS FMP.

Vessels with HMS Angling, CHB, or General category permits that participate in Atlantic billfish tournaments represent the universe of potentially affected vessels of alternative E3. However, given the multi-species nature of the HMS permits and the fishery itself, it is not possible to accurately quantify the subpopulation of billfish anglers. Further, NMFS is not able to quantify the exact number of anglers or vessels participating in tournaments that may be impacted. On average, for the period 1999 – 2004, 47 vessels participated per tournament, however the average varies by month and state from 14 to 131. In 2003 and 2004, there were 244 and 214 registered HMS tournaments, respectively. These figures include all HMS tournaments, including billfish and non-billfish tournaments. On average for the period 1999 - 2004, there were approximately 149 U.S. billfish tournaments annually, ranging from a low of 118 to a high of 179, in any given year, based on RBS data. However, combining the number of tournaments with the average number of vessels per tournaments is not a reliable indicator of how many individual vessels participated in tournaments because many vessels participate in multiple tournaments each year. It is possible, but unlikely, that alternative E3 could result in decreased tournament participation based on real or perceived declines in catches. Tournament participation would not be expected to decrease given the high rates of participation in catch and release fishing and the continued availability of fish for landing under this alternative. Further, as discussed under the analysis of alternative E2, circle hooks have been found to actually improve the likelihood of catching some HMS, including some species of billfish. Economic costs to tournaments would likely be minimal, given the increase in the number of all release tournaments, and tournaments that provide special award categories or additional points for billfish captured and released on circle hooks. As previously discussed, NMFS cannot predict angler behavior with regard to participation in tournaments, demand for CHB trips, or trips taken by individual anglers in reaction to potential circle hook requirements. As such, if any tournaments are cancelled, demand for CHB trips decreases, or trips taken by individual anglers decline as a result of circle hook requirements, there could be some unquantified adverse impacts depending on the size of the tournament or the number of CHB trips that may not be taken.

NMFS received public comment voicing concern that proposed billfish tournament circle hook requirements may decrease catches of some HMS or other species that are landed for prize money. The NED circle hook study shows that deployment of circle hooks in the commercial pelagic longline fishery can result in a decrease in the number of swordfish caught under some oceanographic conditions, however, NMFS has little data on the impact of circle hooks in the recreational swordfish fishery or on other recreationally caught non-HMS species and associated potential socio-economic costs or effects. Importantly, it should be realized that all permitted billfish tournament anglers would be operating under the same Federal regulations, and thus, contrary to concerns expressed by some anglers, there should be no competitive disadvantage relative to one another. Furthermore, the preferred alternative would specifically allow for the deployment of J-hooks with artificial lures in billfish tournaments, which should mitigate some concerns regarding a decrease in catches.

The minor initial economic costs associated with compliance costs of circle hook requirements, and the potential minor long-term positive economic benefit (savings) of approximately $0.46 per hook purchased by anglers for use in HMS fisheries, as discussed under the analysis for alternative E2, would only apply to billfish tournament participants under alternative E3. Billfish tournament participants may be impacted to a slightly greater degree by this requirement, as tournament participants tend to be regular participants in the billfish fishery, and are likely to purchase more hooks than the occasional billfish fisher. Again, however, the purchase of hooks represents only a minor capital expenditure relative to other capital costs in the fishery, including the purchase, equipping, and maintenance of vessels, and tournament registration fees, and thus, the costs are considered *de minimus*.

Impacts of alternative E3 on hook manufactures, retailers, and anglers would likely be limited given that J-hooks would continue to be permitted outside of tournaments, and when using artificial lures in tournaments. As discussed under alternative E2, the delay in implementation of circle hook requirements, specifically requested by HMS and Billfish Advisory panel members and the public during public comment, should allow hook manufacturers, retailers, tournament operators, and anglers adequate time to adjust business practices, become proficient in the use of circle hooks, and utilize current inventories of J-hooks, thereby reducing any economic costs associated with alternative E2. Alternative E3, consistent with the analysis of alternative E2, may result in a temporary decrease or increase in angler consumer surplus, and may result in a long-term increase in angler consumer surplus should this alternative assist in the recovery of Atlantic marlin. Also similar to alternative E2, alternative E3 may result in improved negotiating position at ICCAT, potentially speeding the implementation of recreational circle hooks requirements through ICCAT. As with alternative E2, alternative E3 could present enforcement problems, however, NMFS is confident that between Agency efforts to enforce circle hooks, the increasing use of tournament observers, the conservation ethic of billfish anglers, and the vested financial self-interests of billfish tournament participants in ensuring that all tournament participants compete fairly under the same rules and conditions, high levels of compliance would be expected.

Alternatives E4a and E4b would increase the minimum size for blue and white marlin, likely reducing the number of legally landed blue and white marlin, respectively. NMFS cannot predict angler behavior, and so cannot be sure if these measures would or would not affect angler participation rates. As previously discussed, catch and release rates are already quite high in the billfish fishery, with anglers often keeping only trophy-sized fish. As such, an increase in minimum sizes is not anticipated to dissuade any substantial portion of billfish anglers from pursuing Atlantic marlins. Furthermore, since many tournament organizers already stipulate higher minimum sizes than current Federal regulations, any potential decrease in angler participation, and resultant economic impacts, would likely be minor. Further, increased minimum sizes do not reduce the number of fish available for landing, simply the odds of landing a fish. As such, anglers could continue to pursue and land marlins, should they choose to, given that the ICCAT landing limit would not be impacted by alternative E4. Table 4.49 indicates that between 1999 and 2004, 92, 98, and 99.4 percent of blue marlin, white marlin, and sailfish were released in tournaments, respectively. Fisher and Ditton (1992) conducted a survey of 1,984 billfish anglers and found that these anglers, on average, released 89 percent of billfish depending on the region (range = 74-95 percent). Further, Ditton and Oh (2004) found that some anglers were willing to pay an additional $71 (2004 dollars) to participate in catch and release fisheries. This reinforces NMFS' belief that there would not likely be any substantial adverse socio-economic impacts stemming from an increased minimum legal size limit of the ranges analyzed under alternatives E4(a) and (b).

High catch and release rates coupled with low CPUE for billfish indicate that an increase in the minimum size of four to seven inches for blue marlin and three to seven inches for white marlin would have negligible impacts on angler participation. Fisher and Ditton (1992) also found that 60 percent of respondents either agree or strongly agree with increased minimum sizes. Eighty-one percent of anglers interviewed stated that that the minimum size limits implemented in 1988 had no effect on their billfishing activity. The Agency received comments during the formulation of Amendment 1 to the Billfish FMP (NMFS, 1999) indicating that increasing the minimum size limits would be preferable to implementing bag limits if additional management action is necessary. If angler participation remains consistent, negative social and economic effects or costs would likely be minor as a result of increasing the minimum size for blue or white marlin.

Alternative E5, establishing a bag limit of one Atlantic billfish per vessel per trip, would likely have minor economic costs. Recreational billfish fisheries have very low CPUE rates, however, it is believed that participation in these fisheries continues to expand. Because of the rarity of catching a billfish and the conservative minimum sizes in place, the chances of landing more than one white or blue marlin on a single trip are low. Sailfish are somewhat of an exception, in that during certain times of the year at several locales off the coast of Florida, anglers may have the opportunity to catch and land several sailfish that meet the minimum size requirements in one trip.

Fisher and Ditton (1992) indicate that 77 percent of anglers would not change their fishing behaviour if a bag limit of one billfish were implemented. Based on this and the high levels of catch and release fishing in the recreational billfish fishery, as the fishery continues to expand it is reasonable to assume that anglers would maintain current levels of participation based on the opportunity of catching and possibly landing one trophy billfish. A bag limit of zero billfish, or implementing catch and release only might affect angler behavior more because anglers would no longer have that opportunity to catch an exceptionally large billfish, which is afforded by a one billfish bag limit.

Furthermore, since this is largely a catch and release fishery, both within and outside of tournaments, NMFS assumes that implementing a bag limit would not deter anglers from participating in billfish excursions, likely minimizing the negative impacts to CHB operators. However, it is possible that there would be an unquantifiable decrease in demand for CHB trips if not all individual anglers on a given trip would have the opportunity to land a billfish. As such, multi-angler, multi-day trips could be impacted to a greater extent than day trips if alternative E5 were selected as a preferred alternative.

Tournament participation would not be expected to decrease in a substantial manner as tournament rules often prohibit participants from entering more than one marlin per day, which would also likely prevent participants from possessing multiple fish. The high catch and release ratio indicates that the majority of billfish anglers are more interested in the experience of "hooking" a billfish rather than landing a billfish. If anglers continue to take marlin trips, as anticipated, then many of the economic costs associated with the landing limit would be minimal or non-existent.

Alternative E5 would be anticipated to assist the United States in maintaining compliance with the 250 fish limit adopted by ICCAT. Eliminating the opportunity for vessels to land several blue and/or white marlin would decrease the likelihood of overages, closures, or increases in the minimum size that may occur as a result of achieving the threshold for action described in alternative E6. However, since multiple landings of blue marlin and white marlin are rare, a bag limit in and of itself may not guarantee compliance.

Alternative E6, which would implement ICCAT recreational marlin landing limits, is anticipated to potentially result in minimal to moderate economic costs depending on catch rates, angler response, and which of the available in-season management actions (no action, minimum size increase, or catch and release only) become necessary. As discussed under the analysis of the ecological impacts of this preferred alternative, and consistent with ICCAT recommendations, NMFS would automatically subtract any overharvest from the subsequent fishing year's landing limit, and may carry forward underharvest to the subsequent fishing year. To increase or decrease the annual 250 marlin landings limit as a result of carrying forward future over or underharvest of Atlantic marlins the Agency will publish a notice in the Federal Register. To increase or decrease the 250 marlin recreational landing limit as a result of a new ICCAT recommendation, would require rulemaking under this preferred alternative.

Available historical data suggest it is unlikely that the United States will achieve the 250 marlin landing limit in the near future. (See Table 4.48 for historical landings data, as reported to ICCAT.) As noted under alternative E1, between 2001 and 2004 (inclusive), the United States remained substantially below the ICCAT landing limit with the exception of 2002, when a post-fishing year adjustment to accounting methodologies indicated a small one-time exceedance of the landing limit. At the 2004 ICCAT meeting, the United States reported landing 131 marlin (108 blue marlin, 23 white marlin) based on data from the RBS, landings cards from the States of North Carolina and Maryland, and self-reported non-tournament landed fish. RBS data represented roughly 88 percent of marlin landings reported to ICCAT in 2004. At the 2005 ICCAT meeting the United States reported 149 blue and white marlin combined (118 blue marlin; 31 white marlin). However, the likelihood of achieving the 250 fish limit may change with improved accuracy in quantifying domestic recreational billfish landings. Further, given the open access nature of the fishery, and relatively low compliance with self-reporting requirements, it is possible for documented landings to increase if effort increases and/or if compliance improves with reporting requirements.

There are several unknowns that currently make an assessment of the socio-economic impacts of alternatives E6 difficult to quantify. These include uncertainty regarding total marlin landings, uncertainty regarding the number of marlin fishermen and absolute effort, uncertainty regarding changes in angler behavior when faced with increased minimum sizes or a catch and release only fishery, and limited socio-economic data. As such, the analysis presented in this Consolidated Final HMS FMP is based on the best available data, and makes use of proxies in the discussions of scenarios two and three below, to assist in evaluating the impacts of this alternative. Socio-economic impacts are discussed for CHBs, tournaments, anglers, and associated businesses under three potential management action scenarios for both the June 1 – May 31 fishing year management cycle and the calendar year management cycle: Scenario (1) no in-season adjustments; Scenario (2) implementation of minimum sizes; and, Scenario (3) shift to catch and release only fishery for Atlantic marlins. Socio-economic effects and costs of alternative E6 under scenarios 2 and 3 would vary depending upon the management cycle finalized for the directed billfish fishery.

Scenario 1: Threshold For In-Season Management Action Not Achieved

Alternative E6 would not be expected to result in impacts to the recreational marlin fishery, under either the June 1 – May 31 fishing year or the calendar year management cycle, if the threshold for action is not reached or projected to be reached. Alternative E6 is intended to slow landings by increasing the minimum size of Atlantic blue and/or white marlin, if necessary, thereby allowing landings to continue for the entire duration of the fishing year, in an effort to prevent a shift to catch and release fishing. If the threshold for action is not achieved or expected to be achieved, NMFS anticipates no impact on demand for CHB trips, tournament participation, or participation in the fishery by non-tournament anglers. Under this scenario, NMFS would not anticipate any adverse socio-economic effects on dependant shoreside businesses, such as tackle shops or marinas. Thus, under the no in-season action scenario of alternative E6 (where the threshold for action is not achieved or anticipated to be achieved), NMFS anticipates few or no positive or negative socio-economic effects, while remaining consistent with ICCAT recommendations. As stated above, this conclusion applies regardless of whether the fishery is operating under the June 1 – May 31 fishing year or the calendar year management cycle. As such, the impacts would be similar to those discussed under alternative E1

Scenario 2: Threshold For an In-Season Minimum Size Increase Achieved

Alternative E6 would provide NMFS the option of increasing the minimum sizes of Atlantic blue and white marlin to between 117 and 138 inches and 70 and 79 inches, respectively, if in-season evaluation of the action criteria indicate that additional management measures are necessary to ensure consistency with the ICCAT landing limit. As discussed under the ecological evaluation of alternative E6, the action criteria would include a review of landings, time remaining until conclusion of the current fishing year, current and historical landings trends, and any other relevant factors. Based on RBS landings data (1999 - 2004), approximately 14 percent and 18 percent of BUM and WHM landings, respectively, have occurred at or above the low end of size range available to the Agency for in-season action (117 inches for blue marlin and 70 inches for white marlin).

For purposes of analysis only, this document assumes that the threshold for action is reached in a given year when 85 percent of the ICCAT landings limit (213 fish under the current ICCAT landing limit) has been landed. This threshold for action is for purposes of discussion only and is in no way intended to indicate that that 85 percent is the actual threshold for action. The threshold for action would vary by year based on the action criteria identified above. To determine an approximate date at which the 85 percent threshold might be achieved, the Agency increased the historical RBS landings distribution of marlins evenly by month for the period 1999 – 2004 until the threshold for action was achieved. The assumptions involved in determining the action date would include the following, and are made for only purposes of analysis: (1) the temporal distribution of landings will remain roughly similar to the 1999 – 2004 pattern, as identified from RBS data; (2) landings will increase evenly until at least 85 percent of the ICCAT landings limit is achieved; (3) the 85 percent threshold will be achieved when approximately 85 percent of historical landings have occurred; and, (4) that the Agency benchmark for action is 85 percent of the ICCAT landings limit.

Based on the assumptions identified above, NMFS estimates that the threshold for implementing an increased minimum size could occur on approximately May 3$^{rd}$ under the June 1 to May 31 fishing year, or approximately August 22$^{nd}$, under a calendar year management cycle. This potential action date under the calendar-year management cycle is two days later in the fishing season from the estimated date identified in the Draft Consolidated HMS FMP. The change in date is the result of incorporating 2004 tournament data. Incorporation of the date did not change the estimated action date under the June 1 – May 31 fishing year management cycle. The obvious difference in the length of time from the start of the management period until the action threshold is projected to be achieved (~11 months under the June 1- May 31 fishing year management cycle vs. ~ eight months under the calendar year management cycle) between the two management cycles stems from the dearth of marlin landings during the winter months. As such, because those months with few landings occur during the midst of the June 1 – May 31 fishing year, the time it takes to achieve the threshold for action is lengthened.

In the withdrawn proposed rule (68 FR 54410 September 17, 2003) to implement the ICCAT 250 marlin limit, the date at which 80 percent of landings were projected to occur was identified as October 15. The difference in the projected dates at which point management actions *may* be required as per this document, under the assumptions identified above and under the Fishing Year management cycle, as compared to the withdrawn 2003 proposed rule (May 3 vs. Oct 15) is due to three factors: (1) use of six years of landings data (1999 - 2004) in this analysis versus use of a single year (2002) of landings data in the September 2003 proposed rule; (2) selection, for purposes of analysis, of the action trigger at 85 percent of the ICCAT landing limit in this analysis versus an 80 percent action trigger in the September 2003 proposed rule, given the generally slow pace of landings; and, (3) a dearth of landings during the late fall and winter. Under the June 1 – May 31 fishing year management cycle, May 3 is later in the fishing year than October 15. The difference in the projected dates under the assumptions identified above and under the Calendar Year management cycle, as compared to the withdrawn 2003 (August 22 vs. Oct 15) is due to use of a calendar year fishing year in this document rather than a June 1 – May 31 fishing year, as well as factors one and two, discussed above.

During the period 1999 - 2004, RBS data indicate that a total of 87 blue marlin 117 inches or larger have been landed in tournaments and 40 white marlin 70 inches or larger have been reported landed in tournaments. These sizes equate to an average of approximately 15 blue marlin (14.5) and seven (6.7) white marlin of their respective size classes being landed annually during this period. Thus, it is anticipated that during an average year the minimum size increase scenario under alternative E6 action would likely have the effect of maintaining compliance with the current ICCAT landing limit ($213_{\text{fish prior to minimum size increase}} + 15_{\text{blue marlin 117 inches or larger}} + 7_{\text{white marlin 70 inches or larger}} = 236_{\text{landed fish}}$), while allowing the fishery to continuously operate. This measure would allow for a "buffer" of roughly 14 marlin during an average year, if an in-season minimum size increase were triggered. Such a buffer would be necessary and appropriate given that the analysis is based on an average year, and because of this, anglers can be expected to exceed estimated landings rates in fifty percent of years, and anglers can be expected to fall below estimated landings estimates in fifty percent of years. The buffer is anticipated to allow compliance with the ICCAT landings limit even in those years when landings exceed an average year. The 14 fish would still be available to anglers for landing, however the buffer allows NMFS a reasonable margin of error in the timing of in-season management actions.

The large minimum size range available to NMFS under alternative E6 would provide NMFS the flexibility to respond to multiple in-season scenarios with a minimum of disruption to the fishery. NMFS would have the ability to slow landings and keep the fishery open by choosing a minimum size limit appropriate to allow maximum utilization of the U.S. landing limit, but not exceed it. While the proposed temporary minimum size increases for Atlantic blue and white marlin that could be imposed under alternative E6 would be substantially larger than current minimum sizes (99" BUM, 66" WHM), NMFS believes that, in most cases, anglers would continue to pursue Atlantic marlin. In a review of the public comment submitted to NMFS on this alternative, Agency staff did not find comment on the appropriateness of the proposed minimum size range. The Agency interprets this lack of comment to mean that there were no strong objections by the public to the proposed range of minimum sizes available to the NMFS for in-season action. NMFS did receive a number of comments indicating concern over the size of potential adverse economic impacts that may stem from implementation of the 250 Atlantic marlin landing limit. NMFS does not believe such minimum size increases would substantially decrease demand for charter/headboat trips, trips by individual anglers, or participation in billfish tournaments given the catch and release ethic of billfish anglers (87 to 99.2 percent release rate, see alternative E1) as well as the significant number of fish that would still likely be available for landing under the above scenario. However, as discussed in more detail under the ecological benefits of this alternative, there is no way to predict angler behavior. Angler response may be to maintain current effort for marlin, reduce fishing effort, or shift fishing effort to other species. Should effort be maintained or shifted to other species, adverse socio-economic impacts to the fishing community, including CHB operators, tournament operators, tackle shops, marinas, and others would likely be very limited as anglers would continue to make expenditures to pursue fish recreationally. If effort were switched to other species, billfish tournament operators may see a disproportionate adverse impact of the stakeholders identified above, unless points or prizes were awarded for released billfish or non-billfish species. To this point, some billfish tournaments already operate under a catch and release format with most having award categories for non-billfish species. Taken together, these facts reinforce conclusions that impacts would be limited because anglers would likely continue to participate in tournaments. If effort were reduced as a result of marlin minimum size increases, alternative E6 would likely result in small adverse economic impacts for all stakeholders for the reasons previously identified.

The potential impacts of a minimum size increase for Atlantic marlins under alternative E6 could be noticeably affected, either constrained or increased, by the date at which a minimum size increase may occur in a given fishing year. Given the estimated date (May 3) at which a minimum size increase could occur under the June 1 – May 31 fishing year management cycle and the assumptions made in this analysis, some sense of regional impacts can be outlined. An annual average of 25 billfish tournaments occur in the month of May (Table 4.58), and could potentially be impacted, should the ICCAT limit or threshold be reached during a fishing year. The majority of these tournaments occur in Florida (5), South Carolina (4), and North Carolina (4). On average, Louisiana holds three, with Alabama, Georgia, Texas, and the U.S.V.I. each holding two billfish tournaments in May. Not unexpectedly, the South Atlantic and Gulf of Mexico regions have the highest probabilities of being impacted at this time of year. In addition, the relative size of billfish tournaments (as estimated by the number of participating vessels, Table 4.57) in South Carolina, and North Carolina is large, with both averaging greater than the average size of a billfish tournament (47 vessels). However, as previously stated, the impacts to tournaments from minimum size increases are anticipated to be minimal for the reasons discussed above.

Previously stated conclusions that impacts would likely be limited are reinforced by the facts that only 28 days remain in the fishing year after May 3, a minimum size increase would still allow fishermen to continue to land marlins, and there would still likely be approximately 15 percent of the ICCAT landing limit available for landing. Late season tournaments occurring in May, specifically on the Memorial Day weekend, would likely still operate under this scenario for the reasons discussed above, and given reports suggesting that an increasing percentage of tournaments are adopting a catch and release format. As such, NMFS estimates that there would likely be very limited adverse economic impacts for the CHB fleet, individual anglers, or tournaments resulting from an in-season minimum size increase.

In general, under the calendar year management cycle (preferred alternative G2), if landings of Atlantic marlin increase, recreational billfishing effort and tournaments that occur early in the calendar year should have sufficient catch available. However, billfishing effort and tournaments that occur later in the calendar year could be negatively impacted if the management threshold for action is reached in a given year, in-season restrictions are implemented, and anglers exhibit a negative behavioral response. As discussed above, NMFS estimates that, under calendar year management cycle and the previously stated assumptions, in-season action to increase minimum sizes could be required by August 22 to ensure compliance with the 250 fish limit. To reiterate, this would only occur if the rate of recreational marlin landings increases substantially. On average, August has the greatest number of billfish tournaments of any single month (37). Table 4.58, provides a breakdown of the average number of tournaments by state and month for the period 1999 – 2004, inclusive. The higher number of tournaments in the summer months, as identified in Table 4.58, is reflective of the increased in availability of these fish in more temperate regions such as New England and the Mid-Atlantic bight. Under the calendar year management cycle scenario, the months remaining in the fishing year have significantly fewer tournaments, on average: September (14); October (5); November (5); and, December (5). However, not all of these tournaments would necessarily be adversely impacted as some may be sailfish specific tournaments. Sailfish specific tournaments could experience increases in participation, and thus provide limited positive economic impacts to those communities, if in-season management action for marlin became necessary.

Given the estimated date of August 22nd when a minimum size increase could occur, under the calendar year management cycle and the assumptions made in this analysis, some sense of regional impacts can be outlined. Out of these months, impacts in August appear to be of the most regional concern. This is because during an average year the three billfish tournaments that may occur in the state of Massachusetts and two of three billfish tournaments that may occur in the state of Rhode Island occur in August. However, based on 2004 Atlantic HMS Tournament Registration data, there were a total of 34 tournaments that awarded points or prizes for Atlantic marlin that could be impacted if marlin minimum sizes were increased on August 22nd, under the Calendar year management cycle scenario. This includes marlin tournaments operating during the period August 22 – December 31, inclusive. The majority of these tournaments occurred in Florida (10). Puerto Rico held six, Louisiana and Maryland each held four, New Jersey held three, Texas held two, with Alabama, Massachusetts, North Carolina, Virginia and the U.S. Virgin Islands each holding one marlin tournament. This indicates that Florida has the largest probability of being impacted by any potential shift in minimum sizes, although the impacts may be less acute to the state and/or region given the higher number of tournaments that occur in this area.

Prior discussions that impacts of an in-season minimum size increase would likely be limited, under the calendar year management cycle, are reinforced by the facts that a minimum size increase would allow fishermen to continue to land marlins, and that there would still likely be approximately 15 percent of the ICCAT landing limit available for landing. Late season tournaments would likely still operate under this scenario for the reasons previously discussed (high catch and release rate, fish available for landing, etc.) and because anecdotal reports suggest that an increasing percentage of tournaments are adopting a catch and release format. As such, NMFS estimates that there would likely be limited adverse economic impacts for the CHB fleet, individual anglers, or tournaments.

Tournament data presented in this document are historical and averaged, except where explicitly noted, and do not necessarily reflect the exact time periods of past tournaments or potential future tournaments. Its use as a proxy for interpretation of regional impacts is extremely limited. In some cases, tournament dates could be adjusted to mitigate or avoid potential negative impacts of occurring late in the season with an increased risk for management actions. If, as expected, the potential negative impacts of increasing the size limit is perceived as minor by tournament participants, then tournaments may not be affected at all.

Scenario 3: Threshold for Implementing Catch and Release Only Fishing is Achieved

Under alternative E6, NMFS would be required to shift the entire Atlantic recreational marlin fishery to catch and release if the ICCAT landing limit for any given year is achieved. Under these circumstances, NMFS believes that, in a worst-case scenario, marlin anglers may reduce their demand for charter fishing trips by between 0.4 and 24.2 percent of the available trips remaining during a given season. The range of 0.4 and 24.2 percent is derived from an examination of landings and release data (RBS, MRFSS, LPS) which indicate that between 1999 and 2004, anglers released between 75.8 and 100 percent of blue marlin and between 89.4 and 100 percent of white marlin. Clearly, it is not logical to assume that 100 percent of blue or white marlin are released, given that there have been observed and reported landings during this period. As such, the release estimate of 99.6 percent is used for purposes of analysis as an upper limit of the marlin release rate. This was the highest marlin release rate identified below 100 percent. As such, retention rates of 0.4 percent to 24.2 percent are used as proxies to represent the range of worst-case scenarios of fishermen who do not practice catch and release marlin fishing and completely exit the fishery. The low-end release rate estimate of 75.8 percent used in the Final Consolidated HMS FMP is substantially lower than the 89.4 release rate used in the Draft Consolidated HMS FMP. This is the result of a noticeable drop in the estimated release rate of blue marlin based on updated 2004 MFRSS data. The high-end release rate of 99.6 percent used in this Final Consolidated HMS FMP is slightly higher than the 99.4 percent release rate used in the Draft Consolidated HMS FMP. This is the result of a slighter higher estimate of the white marlin release rate based on updated 2004 MRFSS data.

If the landing limit were achieved earlier in the season, then more trips would logically be impacted as compared with achieving the landing limit later in the season. The average value of a CHB trip was $1,053 (2004 dollars). Data are not available to determine the number of CHB trips targeting marlin in any given month, and, as such, NMFS cannot quantify the impacts of the estimated decrease in participation on CHB operators. While the number of Angling category permits is known, as previously mentioned, it is not possible to determine what proportion of permitted anglers participate in the billfish fishery. As such, it is not possible to quantify an impact on non-CHB billfish anglers. Based on the rationale stated above, NMFS assumes participation in the directed billfish fishery by individual anglers would also decline by 0.4 to 24.2 percent if the marlin fishery is shifted to catch and release only under alternative E6.

Under preferred alternative E6, NMFS estimates that between 0.8 and 10.1 percent of tournaments may cease to operate in a worst-case scenario. This range was derived from the low and high end billfish tournament release rates (RBS data) of 89.9 and 99.2 percent for use as a proxy, and represents a worst case scenario. Approximately 150 billfish tournaments operated annually, on average, for the period 1999 - 2004. If catch and release fishing for Atlantic marlins was implemented for an entire season, this could equate to between 1 and 15 billfish tournaments ($150_{\text{annual billfish tournaments}}$ * $0.008$ to $0.101_{\text{estimated reduction in participation}}$ = $1.2$ to $15.15_{\text{tournaments potentially not operating}}$) not operating, with a potentially minor to substantial direct local and/or regional adverse economic impact. This figure represents an increase of approximately one tournament that may not operate over figures presented in the Draft Consolidated HMS FMP. This change stems from incorporation of 2004 data which had the highest number of billfish tournaments since 1999, and which increased the average number of tournaments per year. The estimated socio-economic impact of one to 15 tournaments ceasing operations ranges from $1,375,439 to $20,631,585 ($1_{\text{tournament stopping operations}}$ * \$1,375,339$_{\text{estimated value of a tournament}}$ = $1,375,439; $15_{\text{tournaments stopping operations}}$ * \$1,375,339$_{\text{estimated value of a tournament}}$ = $20,631,585. Nevertheless, this scenario is highly unlikely, given that the ICCAT landing limit must be achieved prior to the fishery becoming catch and release. The only way this scenario could occur would be if the previous year's overage was of sufficient magnitude to completely fill the next season's landing allocation (e.g., 500 or more marlin were landed in a single year). Only in 2002 did reported U.S. marlin landings exceed the 250 fish limit, and, as previously discussed, by only 29 fish. Additional information regarding the potential impacts to tournaments of achieving the threshold for implementing catch and release only fishing under alternative E6 are discussed below.

To estimate socio-economic impacts given a scenario where the ICCAT landing limit is achieved, NMFS has used the 2002 reported landings (279 marlin) as a proxy for determining when a future switch to catch and release only fishing may occur in the future. The 2002 reported landings are the only available proxy for estimating impacts of achieving the ICCAT landing limit, as this is the only year the ICCAT limit has been achieved. As such, by examining the historical distribution of RBS marlin landings by month (1999 - 2004) and distributing 2002 landings proportionally across the fishing year according to the historical landings pattern, NMFS estimates that, if landings increase evenly during all months to levels that would match 2002 landings, the ICCAT landings limit could be achieved on May 12 based on the current June 1 to May 31 fishing year, and August 25 based on a potential switch to a calendar year management cycle. Again, based on current landings patterns this is unlikely to occur, but it is possible for recorded landings to increase as per previously discussed factors. For purposes of clarity, it should be noted that the close proximity of the dates at which a minimum size increase could occur (May 3rd under a June – May 31 management cycle; August 22nd under a calendar year management cycle), under scenario two, and the date at which a shift to catch and release could occur (May 12th under a June 1 – May 31 management cycle; August 25th under a calendar year management cycle), under scenario three, is a reflection of the different assumptions made for purposes of analysis. They also do not include the anticipated impacts of an in-season minimum size increase that would occur under scenario two. As such, readers should not draw the conclusion that a minimum size increase would be followed just days later by a shift to catch and release fishing (under either the June 1 – May 31 management cycle or the calendar year management cycle).

The economic impacts of switching to a catch and release marlin fishery on May 12 (under the June 1 to May 31 fishing year), under the assumptions made for purposes of this analysis, would likely be minor. There are only 19 days left in the June 1 - May 31 fishing year at that point. Using 2004 tournament data for purposes of analysis, there were 16 registered marlin tournaments in May. Of these, three operated prior to May 12th; the point at which catch and release only fishing could be required under this analysis. Of the 13 billfish tournaments occurring after the May 12 "closure" date, it is anticipated that 0.8 to 10.1 percent may cease operations based on the previously discussed assumptions, which equates to between zero and one tournaments based on standard rounding practices, ($13_{\text{tournaments}} * 0.008 \text{ to } 0.101_{\text{estimated decrease in participation}} = 0.1 \text{ to } 1.3_{\text{tournaments stopping operations}}$). However, even these low numbers may be an over estimate as Ditton and Stoll (2004) suggest that at least some anglers would be willing to pay as much as $71 (2004 dollars) over current entry fees to participate in catch and release tournaments (Ditton, 2004). The estimated date for a shift to catch and release fishing under the June 1 – May 31 management cycle provides a limited ability to identify potential regional impacts. The 13 marlin tournaments occurring late in the 2004 fishing year were held in North Carolina, South Carolina, Louisiana, Texas, Alabama, Florida, Puerto Rico, and Georgia. Four occurred in North Carolina, three in Louisiana, and one each in South Carolina, Texas, Alabama, Puerto Rico, Georgia, and Florida. Most were clustered around the Memorial Day weekend. Depending on which tournaments may potentially cease operating, the impacts could occur in different regions. Given the locations of the tournaments, North Carolina would have the highest probability of being adversely impacted of any single state, followed by Louisiana. The South Atlantic region would have the greatest probability of being adversely impacted with seven of the 13 tournaments that could be among those affected. The Gulf region would have a slightly lower probability of being impacted with five of the 13 tournaments, and Puerto Rico would be least likely to be adversely impacted. While states with the smallest number of tournaments would be less likely to be impacted, they would be expected to realize heightened localized adverse impacts if a tournament were canceled. However, there is no way to accurately predict exactly which tournaments may continue to operate or cease operating. Using an average value of $1,339,800 for an average HMS tournament (Ditton and Clark, 1994, converted to 2003 dollars), should one tournament cease operations as a result of alternative E6, this could result in an estimated adverse economic impact of $1,339,800 dollars to the local community, including tournament operators, CHB operators, marinas, and others. Loss of a single tournament would likely result in some small decrease in angler consumer surplus to the vessels participating in that tournament. Data indicate that on average, approximately 47 vessels participate in Atlantic billfish tournaments (Table 4.57). Impacts on shoreside businesses would likely be minor, but could be increased or decreased depending on angler response and when in the season a shift to catch and release only fishing might occur.

The economic impacts of switching to a catch and release marlin fishery on August 25th, under the calendar year management cycle and the assumptions made for purposes of this analysis, would likely be limited. There are, on average, 66 billfish tournaments that occur between August and December, inclusive. However, for the period 2001 – 2004 (inclusive), 27 of these billfish tournaments, on average, were either sailfish or swordfish tournaments that did not award points or prizes for Atlantic marlin, or concluded prior to the estimated action date of August $25^{th}$. This leaves a universe of approximately 39 tournaments that award points or prizes for Atlantic marlin during an average year that could be impacted by a shift to catch and release fishing on August $25^{th}$, if necessary for ICCAT compliance purposes. Of the 39 billfish tournaments occurring after the August 25th "closure" date, it is anticipated that 0.8 to 10.1 percent may cease operations based on the previously discussed assumptions. This equates to between zero and four tournaments being impacted based on standard rounding practices (39 $_{\text{tournaments}}$ * 0.008 to 0.101 $_{\text{estimated decrease in participation}}$ = 0.312 to 3.9 $_{\text{tournaments stopping operations}}$). The estimated universe of tournaments that may be impacted is smaller in this Final Consolidated HMS FMP than was estimated than under the calendar year scenario in the Draft Consolidated HMS FMP. This is the result of further refining the data used in the assessment. In this document, sailfish or swordfish specific tournaments (billfish tournaments that awarded points or prizes only for sailfish or swordfish and thus would not be adversely impacted by a shift to catch and release fishing for marlins) were removed from the universe of potentially affected billfish tournaments. The result is a more accurate accounting of "marlin" tournaments that may possibly be impacted by a shift to catch and release only marlin fishing. As such, the number of tournaments potentially impacted by an inseason shift to catch and release is considered more accurate.

The distribution of potential regional impacts would be similar to those discussed above under Calendar year management cycle scenario two (an in-season minimum size increase) given the proximity of the estimated dates at which a minimum size increase or shift to catch and release only fishing could occur. While states with the smallest number of tournaments would be less likely to be impacted, they would be expected to realize heightened localized adverse impacts if a tournament were canceled. However, there is no way to accurately predict exactly which tournaments may continue to operate or cease operations. Using an average value of $1,375,439 for an average HMS tournament (Ditton and Clark, 1994, converted to 2004 dollars), should zero to four tournaments cease operations as a result of alternative E6, under a worst case scenario this could result in an estimated adverse economic impact of $0 to $5,501,756 dollars to the local community, including tournament operators, CHB operators, marinas, and others (0 $_{\text{tournaments stopping operations}}$ * \$1,375,339 $_{\text{estimated value of a tournament}}$ = \$0; 4 $_{\text{tournaments stopping operations}}$ * \$1,375,339 $_{\text{estimated value of a tournament}}$ = \$5,501,756). Loss of up to four tournaments would likely result in some small decrease in angler consumer surplus to the vessels participating in those tournaments. However, even these low numbers may be an over estimate as Ditton and Stoll (2004) suggest that at least some anglers would be willing to pay as much as $71 (2003 dollars converted to 2004 dollars) over current entry fees to participate in catch and release tournaments (Ditton, 2004). Data indicate that on average, approximately 47 vessels participate in Atlantic billfish tournaments (see Table 4.57). Impacts on shoreside businesses would likely be minor, but could be increased or decreased depending on angler response and when in the season a shift to catch and release only fishing might occur. Further, should a marlin fishery "closure" occur as a result of alternative E6, this could result in positive economic impacts for operators of sailfish or swordfish specific tournaments and CHB operators who specifically target these species, if anglers shift effort to these other billfish species. NMFS is unable to quantify these impacts, as angler behavior cannot be predicted.

Under either the June 1 – May 31 management cycle or the calendar year management cycle, Alternative E6 could have smaller long-term adverse socio-economic impacts than Alterative E1, the No Action alternative, if landings increase in the future. Alternative E6 would allow NMFS significant flexibility in determining if and when action should be taken to remain consistent with international obligations. Alternative E6, would allow the response to be tailored to the peculiarities of a given fishing year to ensure maximum utilization of the ICCAT landing limit. This response would likely allow the Agency to avoid disproportionately impacting CHB operators, tournaments, and anglers who fish for marlin late in the fishing year by providing anglers the greatest opportunity to land marlin over the entire length of the fishing year. Alternative E1 would simply result in the shutdown (catch and release fishing only) of the fishery on an emergency basis if the ICCAT landing limit were achieved. The shift to catch and release only fishing under the no action alternative would likely occur at an earlier point in the season than under alternative E6, where landings would first be slowed by increasing the minimum size, and then prohibited if the landings reached the ICCAT landing limit. Alternative E6 is anticipated to allow a shutdown of the marlin fishery to be avoided, and at a minimum, significantly extend the open period of the fishing year prior to a closure, thereby minimizing negative socio-economic impacts. Alternative E6 may result in a temporary decrease in angler consumer surplus if increased minimum sizes or catch and release requirements were implemented for the remainder of a fishing year. The loss of angler consumer surplus should be mitigated to an extent by the ability of anglers to continue to land fish if the minimum size is increased, the availability of other billfish species for landing, and given that existing minimum sizes and the ability to land fish would be restored at the start of the next fishing year.

A number of commenters expressed concern that potential impacts of a shift to catch and release fishing would have dramatic and substantial adverse economic impacts. NMFS fully appreciates these concerns, and recognizes that some areas may have heightened localized impacts. However, this alternative was specifically constructed, in part, to minimize the potential adverse impacts of implementing a non-discretionary international obligation by allowing NMFS substantial flexibility in determining when to respond, and how to respond, should marlin landings approach the international limit. The alternative is designed to allow the fishing season to continue with a minimum of disruption as long as possible, and then when action may be required, implementing management measures that would still allow for the fishery to continue. Between angler's conservation ethic, as witnessed by the high rate of catch and release, the current low rate of marlin landings, the availability of other billfish species for landing, and the flexibility built into this alternative, NMFS anticipates that impacts would be limited, and any unavoidable impacts would be substantially mitigated.

Alternative E7, a shift to catch and release only fishing for Atlantic white marlin for five years, could potentially lead to negative social and economic effects, although the magnitude is difficult to assess. As discussed under alternative E1, the majority of data indicate a strong adherence by Atlantic billfish anglers to catch and release fishing for white marlin. Based on RBS, LPS, and MRFSS data, NMFS estimates that between 0.4 percent and 10.6 percent of all white marlin catches are landed (Table 4.49, Table 4.50, and Table 4.51).

As of February 1, 2006, there were 25,238 Angling, 4,173 CHB, and 4,824 General category permit holders. See Chapter 3 for additional permit information. Given the multi-species nature of HMS permits, and the fact that vessels are permitted rather than individual anglers, NMFS does not have the ability to identify what subset of these permitted vessels, or how many anglers, participate in the recreational billfish fishery.

It is difficult to estimate the percentage of Angling category fishing trips that would not be taken if catch and release fishing for white marlin was mandatory, however the Agency acknowledges that some percentage of total Angling category trips would likely be canceled due to the inability to land a white marlin. Ditton and Stoll (2003) estimate that there are 7,915 billfish anglers in the U.S. Atlantic and 1,627 billfish anglers in Puerto Rico. Angler expenditures for marlin targeted trips are estimated to be $704.00 per angler (in 2004 dollars), based on a limited sample size. In contrast, angler expenditures for other HMS targeted trips are estimated at $125.00 per angler (in 2004 dollars), based on 621 observations (NMFS, 2001). Ditton and Stoll (2003) report that a 1990 study estimated average expenditures of $2,105.00 ($3,042.00 in 2004 dollars) for Atlantic billfish trips and that a 1994 study estimated a mean expenditures of $1,052.00 ($1,341.00 in 2004 dollars) for Puerto Rico billfish trips. As reported by Ditton and Stoll (2003) the aggregate economic impact of billfish fishing trips in the U.S. Atlantic is conservatively estimated to be $22.7 million annually, not including Puerto Rico. These data indicate that billfish anglers place a high value on billfish fishing. Under alternative E7, Angling category fishermen may reduce the number of trips targeting white marlin. Reduced participation in the billfish fishery would likely result in negative social and economic impacts for this sector. Considering the overwhelming catch and release ethic of billfish anglers (31 white marlin reported landed in 2004), however, NMFS anticipates that any negative social and economic impacts under this alternative would be small. The short-term social impacts of not being able to land trophy or record category fish is difficult to assess, however NMFS anticipates that this alternative could lead to a decrease in angler consumer surplus. The long-term impacts of alternative E7 may result in an increase in net benefits as stocks rebuild and recreational encounters with white marlin become more frequent.

Sutton *et al.* 1999, estimate that CHB operators each take 109 for-hire trips per year on average, with approximately 2.6 percent of those trips targeting billfish. Multiplying the average number of CHB trips by the number of CHB permits ($109_{\text{avg. CHB trips per year}} * 4{,}173_{\text{CHB permits}} = 454{,}857$) and multiplying the product by 0.026 ($454{,}857_{\text{total CHB trips}} * 0.026_{\text{percentage of CHB billfish trips}} = 11{,}826$) provides a rough estimate of the annual number of billfish trips taken by CHB operators. Of the 11,826 CHB trips targeting billfish, between 47 and 1,254 trips may be canceled given the inability to retain white marlin ($454{,}857_{\text{CHB trips}} * 0.026_{\text{percent of CHB trips BLF directed}} * .004_{\text{WHM low retention rate}} = 47.3$) ($454{,}857_{\text{CHB trips}} * 0.026_{\text{percent of CHB trips BLF directed}} * 0.106_{\text{WHM high retention rate}} = 1{,}253.5$). NMFS estimates that the cost of a CHB trip currently averages $1,053.00 (in 2004 dollars). Given this figure, the Agency estimates that alternative E7 could result in between $49,491 and $1,320,462 in lost revenues to CHB vessels ($47_{\text{estimated lost trips}} * \$1{,}053.00_{\text{avg. cost per trip}} = \$49{,}491$) ($1{,}254_{\text{estimated lost trips}} * \$1{,}053.00_{\text{avg. cost per trip}} = \$1{,}320{,}462$). The loss of revenues of this magnitude would likely result in minor to moderate negative social and economic impacts to the CHB sector. While NMFS cannot definitively forecast angler behavior, given the previously discussed catch and release ethic of billfish anglers (31 white marlin reported landed in 2004), NMFS anticipates that most anglers would continue to fish for Atlantic white marlin under catch and release restrictions. As such, NMFS anticipates that negative impacts under this alternative would be less severe than those estimated above. Further, the continued ability of anglers to pursue and land other Atlantic billfish species, and other non-HMS may further mitigate potential adverse impacts, which may result from this alternative.

General category permit holders are only allowed to fish for, retain, or possess white marlin in registered HMS tournaments; however the Agency does not possess information regarding how many General category permit holders participate and land white marlin in tournaments. Under alternative E7, negative social and economic impacts could occur if General category vessels that normally participate in HMS tournaments cease operations. Potential negative impacts would not likely be realized by those General category vessels that already practice catch and release fishing for white marlin or participate in catch and release tournaments, because NMFS anticipates that these anglers would continue to pursue Atlantic white marlin under a catch and release only fishery.

In 2004, there were 129 registered tournaments that awarded points or prizes for white marlin captures (see Chapter 3). Based on RBS data from 1999 – 2004 (Table 4.49), the retention rates of white marlin in tournaments range from 0.8 percent to 3.2 percent. For purposes of analysis only, NMFS assumes that under a worst-case scenario, that this same percentage (0.8 to 3.2 percent) of tournaments may stop operating. Under these assumptions, NMFS estimates that alternative E7 may result in between one and four tournaments would not continue to operate in a catch and release only fishery for white marlin. As previously discussed, NMFS estimates the average value of an HMS tournament to be $1,375,439 (in 2004 dollars). Assuming that one to four tournaments cease operations, the Agency estimates that alternative E7 could result in negative economic impacts ranging from $1,375,439 to $5,501,756. The loss of revenues of this magnitude would likely result in moderate social and economic impacts for tournaments, tournament participants, and associated businesses. While NMFS cannot definitively forecast angler behavior, given the previously discussed catch and release ethic of billfish anglers, NMFS anticipates that most anglers would likely continue to pursue white marlin under a catch and release only fishery and most tournaments would continue to operate under a revised format. As such, adverse impacts under this alternative would likely be of a lesser magnitude than those estimated above. Additionally, a recent survey based on tournament anglers in Texas, determined that angler willingness to pay is $71.00 (in 2004 dollars) higher for participation in catch and release tournaments than it is for participation kill tournaments (Ditton and Oh, 2004).

Negative social and economic impacts resulting from alternative E7 may be mitigated by a delayed effective date for implementing a catch and release only requirement for Atlantic white marlin of January 1, 2007. A delayed effective date would be anticipated to allow tournament operators limited time to alter tournament rules to provide for a catch and release format and allow anglers to adjust to new requirements.

Angler consumer surplus would likely remain high, given the currently high release rate of white marlin, which is reinforced by the low number of verified landings that occurred in recent years. However, it is possible that angler consumer surplus may decrease given the inability to land white marlin. Further, under alternative E7, anglers would still have the ability to land other billfish, including trophy-sized sailfish and blue marlin. To mitigate negative socio-economic impacts, alternative E7 would delay implementation of catch and release only fishing requirements to allow the fishery time to adjust to new measures, and would include a sunset provision five years from implementation of catch and release requirements. Alternative E7 would likely provide limited benefit for the species and likely result in lesser socio-economic impacts to the billfish community than alternative E8.

During the public comment period, NMFS received strong comment opposed to the Atlantic white marlin catch and release alternative. Based on public comment that indicated more significant concerns over potential adverse economic impacts to the fishery if catch and release only fishing for Atlantic white marlin were required, as well as a number of other factors, including but not limited to, the impending receipt of a new stock assessment for Atlantic white marlin and upcoming international negotiations on Atlantic marlin, the Agency does not prefer to prohibit landings of Atlantic white marlin, at this time. Additionally, NMFS received substantial comment in support of this measure. The commenters supporting the white marlin landings prohibition stated concerns over stock status, the ESA listing review, and an interest in maintaining leadership at the international level. The implementation of circle hook requirements would be an important first step in reducing mortality in the directed billfish fishery. NMFS will consider catch and release only fishing options for white marlin as well as other billfish conservation measures in future rulemakings, as necessary and appropriate.

Similar to alternative E7, alternative E8 could potentially lead to negative social and economic impacts, although the magnitude is difficult to assess. As discussed under alternative E1, the majority of data indicate a strong adherence by Atlantic billfish anglers to catch and release fishing for blue marlin. Based on RBS, MRFSS, and LPS data, NMFS estimates that between 3.9 percent and 24.2 percent of all blue marlin catches are landed (Table 4.49, Table 4.50, and Table 4.51).

As of February 1, 2006, there were 25,238 Angling, 4,173 CHB, and 4,824 General category permit holders. Given the multi-species nature of HMS permits, and the fact that vessels are permitted rather than individual anglers, NMFS does not have the ability to identify what subset of these permitted vessels, or how many anglers, participate in the recreational billfish fishery. It is difficult to estimate the percentage of Angling category fishing trips that would not be taken if catch and release fishing for blue marlin was mandatory, however the Agency acknowledges that some percentage of total Angling category trips would likely be canceled due to the inability to land a blue marlin.

Under alternative E8, Angling category fishermen may reduce the number of trips targeting blue marlin. Reduced participation in the billfish fishery would likely result in negative social and economic effects and costs for this sector, however, considering the catch and release ethic of billfish anglers (118 blue marlin reported landed in 2004), NMFS anticipates that the economic costs under this alternative would not be large. The short-term social impacts of not being able to land trophy or record category fish is difficult to assess, however NMFS anticipates that this alternative could lead to a decrease in angler consumer surplus. The long-term impacts of alternative E8 may result in an increase in net benefits as stocks rebuild and recreational encounters with blue marlin become more frequent.

Using the same assumptions discussed above, the Agency estimates that of the 454,857 CHB trips occurring yearly, 11,826 of those are billfish directed CHB trips (454,857 * 0.026 Percent of BLF directed CHB trips = 11,826). Of the 11,826 CHB trips targeting billfish, between 461 and 2,862 trips may be canceled given the inability to retain blue marlin (454,857 CHB trips * 0.026 percent of CHB trips BLF directed * 0.039 BUM low retention rate = 461.2) (454,857 CHB trips * 0.026 percent of CHB trips BLF directed * 0.242 BUM high retention rate = 2,862.0). NMFS estimates that the cost of a CHB trip currently averages $1,053.00 (in 2004 dollars). Given this figure, the Agency estimates that alternative E8 would have greater economic costs than alternative E7 and could result in between $485,433 and $3,013,686 in lost revenues to CHB vessels annually. The loss of revenues of this magnitude would likely result in moderate negative social and economic impacts to the CHB sector, however considering the catch and release ethic of billfish anglers, NMFS anticipates that negative impacts under this alternative would be of a lesser magnitude than those calculated above.

General category permit holders are only allowed to fish for, retain, or possess blue marlin in registered HMS tournaments; however the Agency does not possess any information regarding how many General category permit holders participate and land blue marlin in tournaments. Under alternative E8, negative social and economic impacts could occur if General category vessels that normally participate in HMS tournaments cease operations. Potential negative impacts would not likely be realized by those General category vessels that already practice catch and release fishing for blue marlin or participate in catch and release tournaments, because NMFS anticipates that these anglers would continue to pursue blue marlin under a catch and release only fishery. As such, adverse impacts under this alternative would likely be of a lesser magnitude than those estimated above.

In 2004, there were 142 registered tournaments that awarded points or prizes for blue marlin captures (see Chapter 3). Based on RBS data from 1999 – 2004 (Table 4.49), the retention rates of blue marlin in tournaments range from 6.7 percent to 10.1 percent. For purposes of analysis only, NMFS assumes that under a worst-case scenario, that this same percentage (6.7 to 10.1 percent) of tournaments may stop operating. Under these assumptions, NMFS estimates that under alternative E8 between ten and 14 tournaments would not continue to operate in a catch and release only fishery for blue marlin. As discussed above, NMFS estimates the average value of an HMS tournament to be $1,375,439 (in 2004 dollars). Assuming that ten to 14 (142 tournaments * 0.067 to 0.101 decrease in tournament participation = 9.5 to 14.3 tournaments that may cease operations) tournaments cease operations, the Agency estimates that alternative E8 could result in negative economic impacts ranging from $13,754,390 to $19,256,146. The loss of revenues of this magnitude would likely result in sizeable local negative social and economic impacts for tournaments, tournament participants, and associated businesses, however, considering the catch and release ethic of billfish anglers, NMFS anticipates that negative impacts under this alternative would be of a lesser magnitude than those calculated above. Relative to the fishery as a whole, these impacts would be minor, however, as stated; the localized impacts may be felt more acutely. Additionally, a recent survey based on tournament anglers in Texas, determined that angler willingness to pay is $71.00 (2004 dollars) higher for participation in catch and release tournaments than it is for participation kill tournaments (Ditton and Oh, 2004).

Negative social and economic impacts resulting from this alternative may be mitigated by a delayed effective date of implementing a catch and release only requirement for Atlantic blue marlin. A delayed effective date is anticipated to allow tournament operators sufficient time to alter tournament rules to provide for a catch and release format and allow anglers to adjust to new requirements.

Under alternative E8, angler consumer surplus would likely remain high, given the currently high release rate of blue marlin, which is reinforced by the low number of verified landings that occurred in recent year. However, it is possible that angler consumer surplus may decrease given the inability to land blue marlin. Further, under alternative E8 anglers would still have the ability to land other billfish, including trophy-sized sailfish and white marlin. To mitigate negative socio-economic effects and cost, alternative E8 would delay implementation of catch and release only fishing requirements to allow the fishery time to adjust to new measures, and would include a sunset provision five years from implementation of catch and release requirements.

As discussed above, it is appropriate for the Agency to investigate potential options to reduce domestic mortality rates for blue marlin. This alternative was analyzed but not preferred in the Draft Consolidated HMS FMP or in this Final Consolidated HMS FMP due to potentially severe negative social and economic impacts, limited conservation benefits, the anticipated receipt of a new stock assessment in the near future which may provide significant new information on the fishery, and other reasons. The United States will continue its efforts to reduce billfish mortality both domestically and at the international level. Additionally, the Agency may consider catch and release only options for Atlantic blue marlin as well as other billfish conservation measures in future rulemakings, as necessary and appropriate.

*Conclusion*

As described in Chapter 1, the objectives of this document are multifaceted and include, *inter alia*, reducing mortalities of Atlantic billfish in directed and non-directed fisheries. This can be achieved, in part, by addressing known sources of mortality (including landings and post-release mortalities) in the directed recreational marlin fishery. Preferred alternatives E3 and E6 would strike an appropriate balance between conserving living marine resources and maintaining robust recreational fisheries while achieving the objectives of Consolidated HMS FMP. The preferred alternatives would be anticipated to substantially reduce the post-release mortality of Atlantic white marlin and are likely to provide positive ecological benefits for other species, including blue marlin, sailfish, tunas, and others with which recreational billfish fishermen interact, while maintaining consistency with United States' international obligations. The delayed date of effectiveness for preferred alternative E3 would be anticipated to mitigate, to the extent practicable, adverse economic impacts and losses in angler consumer surplus by allowing: tournament operators adequate time to adjust advertising, rules, business practices, and tournament formats; existing stockpiles of J-hooks to be used; and, anglers time to become comfortable and proficient with newly required gear. High levels of adherence to the practice of catch and release fishing, as well as the ability of anglers to continue to use J-hooks outside of tournaments, or in tournaments when deploying artificial lures, should also further substantially mitigate socio-economic impacts. The suite of preferred alternatives would achieve the purpose and scope of this rulemaking by providing comprehensive and meaningful protection to Atlantic billfish, maintaining a robust directed fishery for billfish, and achieving legal and policy obligations. Importantly, by providing a successful roadmap for billfish conservation, NMFS may provide the impetus for other nations to adopt similar management measures, thereby improving conservation of Atlantic billfish throughout their entire range.

## 4.3 Management Program Structure

### 4.3.1 Atlantic Bluefin Tuna Quota Management

#### *4.3.1.1 BFT Quota Management in the General and Angling Categories*

As described in Chapter 2, the alternatives considered for BFT time-period subquotas in the General and Angling categories are:

F1 Maintain the time-periods, subquota allocations, and geographic set-asides for the General and Angling categories as established in the 1999 FMP (No Action)

F2 Establish General category time-periods, subquotas, and geographic set-asides annually via framework actions

*F3 Amend the management procedures regarding General category time-periods, subquota, as well as geographic set-asides to allow for future adjustments to take place via a regulatory framework action – Preferred Alternative*

F3(a) Establish monthly General category time-periods and subquotas (June-Jan; 12.5 percent each)

F3(b) Revise General category time-periods and subquotas to allow for a formalized winter fishery (June-Aug, 54 percent; Sept, 26.5 percent; Oct-Nov, 9 percent; Dec, 5.2 percent; and Jan, 5.3 percent)

*F3(c) Revise General category time-periods and subquotas to allow for a formalized winter fishery (June-Aug, 50 percent; Sept, 26.5 percent; Oct-Nov, 13 percent; Dec, 5.2 percent; and Jan, 5.3 percent) – Preferred Alternative*

F3(d) Revise General category time-periods and subquotas to allow for a formalized winter fishery (June-Aug, 38.7 percent; Sept, 26.6 percent; Oct-Nov, 13 percent; Dec, 10.8 percent; and Jan, 10.9 percent)

*F4 Clarify the procedures for calculating the Angling category school size-class BFT subquota allocation and maintain the Angling category North/South dividing line – Preferred Alternative*

*Ecological Impacts*

Minimal, if any, ecological impacts would be expected as a result of adjusting the General category time-periods and/or associated subquotas and/or amending the school size-class tolerance calculation because the overall quotas and size-classes of BFT being targeted by each domestic quota category would not change. In the case of the General category, only the proportion of the coastwide General category quota assigned to each time-period would be altered. For example, even though the time-period subquota percentage for December and January would be increased, the time-period subquota for June through August would be decreased. As a result, there might be increased harvest in the later portions of the General category BFT season, but there would also be a corresponding decrease in harvest in the earlier portions of the season. These small orders of change, quantified in either numbers of fish or in weight (mt), or time and/or location of harvest, compared to overall U.S. harvest levels as recommended by ICCAT under the 20-year rebuilding program, equate to ecological impacts that are unlikely to be measurable given the variability in the data used to conduct BFT stock assessments. Additionally, the numbers of BFT harvested from each different size-class would remain consistent with the levels of BFT mortality used in the stock assessment. Therefore, only negligible ecological impacts would be expected from the following alternatives, as they relate to the ICCAT-recommended rebuilding plan for BFT.

Alternative F1 (No Action), would maintain the General category time-period subquota allocation scheme and the Angling category size-class subquota allocation procedures, as stated in the 1999 FMP. The BFT fishery has been managed via these allocations and procedures since the implementation of the 1999 FMP. These allocations and procedures are consistent with the ICCAT recommendations; therefore, NMFS does not expect this alternative to result in any negative ecological impacts beyond those accounted for in the 20-year BFT rebuilding plan.

Alternative F2 would establish General category time-periods, subquotas, and geographic set-asides annually via a framework action, and may have slightly different ecological impacts from alternative F1, as the time-periods, subquotas, and/or geographic set-asides may shift temporally and geographically from one year to the next. These ecological impacts would be expected to be negligible as well. These shifts could decrease or increase protected resource interactions, discards, and incidental catch of other finfish and would likely need to be analyzed each year depending on the changes proposed. However, as compared with other commercial gear types, commercial handgear typically produce relatively low levels of bycatch and bycatch mortality. Bycatch in the commercial handgear fishery can be monitored via the Large Pelagics Survey (LPS), but may be unaccounted for if the fishery is prosecuted in those areas outside LPS coverage or after the LPS sampling season is concluded. The LPS samples private and for-hire vessels and their landings from offshore fishing trips that target HMS in Virginia through Maine from June through October. A separate source of bycatch information can be derived from vessel logbook programs associated with other non-HMS fisheries in which HMS permitted vessel owner/operators may participate. At this time, there is little information on commercial handgear bycatch. Anecdotal reports suggest that there may be low level of tuna discards due to minimum size restrictions. This process of establishing General category time-periods and associated subquotas annually via a regulatory framework action would not noticeably alter current fishing methods or effort. Therefore, no noticeable adverse or positive ecological impacts would be expected from this alternative. For further information/analyses regarding commercial handgear interactions with protected resources, see Section 3.4.3.

Alternative F3, a preferred alternative, would remove specific General category time-period, subquota, and geographic set-aside language from the consolidated HMS FMP. This alternative would also codify the time-periods and the associated subquota allocations, including allocation percentages and the corresponding quota tonnage, in the regulatory text implementing the consolidated FMP and would remove the New York Bight set-aside. The sub-alternatives F3(a) through F3(d) appear to have similar ecological impacts as those presented in alternatives

F1 and F2, in the sense that the BFT baseline quotas would be consistent from one year to the next, provided the ICCAT-recommended U.S. BFT TAC remains consistent. There may be a slight shift in BFT landings, both temporally (to later in the season) and geographically to the South. However, the number of BFT harvested from each different size-class would remain consistent with the levels of BFT mortality used in the stock assessment. These temporal and spatial shifts in landings may present decreases or increases regarding protected resource interactions, discards, and incidental catch of other finfish. However, for the same reasons mentioned in alternative F2, NMFS does not expect any adverse ecological impacts associated with this alternative. For further information/analyses regarding commercial handgear interactions with protected resources, see Section 3.4.3.

Alternative F4, a preferred alternative, would clarify the procedures for calculating the Angling category school size-class BFT subquota allocation. Specifically, the eight percent school BFT tolerance for the Angling category would be determined prior to removing the NED Statistical set-aside allocation, resulting in a slight increase (*i.e.*, 0.02 percent) in the school BFT baseline quota allocation. Public comment supported the procedural change to calculating the school size subquota. Effort on the school size-class BFT would not be expected to increase as a result of this alternative, due to the very minor increase in available quota. Therefore, substantial changes in either current fishing methods or interaction rates with protected resources or other finfish would not be expected. This alternative has been slightly modified from that proposed in the draft HMS FMP. This preferred alternative modifies the proposed alternative in the draft FMP by retaining the North/South Angling category dividing line located at 39º 18 minutes N. latitude (Great Egg Inlet, NJ) (Table 2.1). As this modification to the alternative would not alter the Angling category quota or the overall U.S. BFT TAC, nor the effort expended by recreational participants, NMFS would not expect any adverse ecological impacts associated with this alternative.

NMFS, based on the best scientific information available, is unaware of any definitive ecological impacts on protected resources that would be associated with implementation of any of the alternatives discussed in this section. Limited data are available on the interactions of commercial and recreational handgear with protected resources, marine mammals, and other finfish. NMFS will continue to monitor HMS handgear fishery interactions with protected resources, marine mammals, and non-targeted finfish and will work to resolve any issues that may arise.

*Social and Economic Impacts*

Alternative F1 would maintain the historical General category time-period and subquota allocation scheme as well as the process used to establish it, *i.e.*, specific details would remain in the 1999 FMP itself. This alternative would require an FMP amendment to adjust these time-periods, subquota percentages, and/or geographic set-asides. This alternative may have both positive and negative social and economic impacts. The positive impacts would be attributed to the General category time-periods and associated subquota allocation percentages remaining consistent with those of prior years (Table 4.59), as well as maintaining the General category New York Bight set-aside allocation for those participants operating in that designated area. The adverse impacts associated with the General category would consist of hindering NMFS' ability to adapt BFT management measures to account for variations inherent to the fishery from one year to the next due to the timeframes associated with conducting an FMP amendment. The positive impacts, in regards to the Angling category would entail maintaining the North/South dividing line; thereby providing a more equitable geographic and temporal distribution of recreational fishing opportunities by separating each BFT size-class subquota into two geographical regions and ensuring reasonable recreational fishing opportunities in all geographic areas without risking overharvest of the Angling category quota. The adverse impacts associated with maintaining the North/South dividing line would be the continued perception that the Agency has the appropriate recreational data in a timely fashion to use this management tool to adjust daily retention limits thus providing fair and equitable recreational fishing opportunities in real-time.

This alternative would also have some adverse social and economic impacts on fishermen, dealers, and the support industries located in the South Atlantic region. Under the No Action alternative, the General quota allocation is heavily frontloaded in the season and if high catch rates were to occur, the quota could be harvested in full prior to the BFT arriving off the coast of South Atlantic states. This uncertainty regarding the amount of BFT quota available late in the season does not allow for businesses to plan accordingly. For instance it is vital for fishermen to obtain the appropriate gear and outfit the vessel properly; or as a dealer, to maintain the appropriate staff and shipping/packing material as well as maintain leases, etc; or in the case of a support industry like a bait/tackle supplier, to have the appropriate gear pre-ordered so it is available for purchase. These adverse impacts could be mitigated if South Atlantic General category participants were to travel north in the early portion of the season. Overall, the adverse social and economic impacts associated with this alternative would be expected to outweigh the positive impacts.

The potential gross revenues generated under the No Action alternative were calculated for each specific time-period by using the status quo time-period subquota allocation percentages, the whole weight equivalent (in metric tons and pounds), and the average ex-vessel prices (whole weight) for 1999 through 2004, inclusive.

**Table 4.59 Alternative F1: Gross revenues associated with the No Action alternative regarding the General Category time-period subquota allocation.***

| Time-Period | Percentage | Equivalent in mt* | Approx. Equivalent in lb* | Average Ex-Vessel $ ('99-'04) | Gross Revenues |
|---|---|---|---|---|---|
| JUNE - AUG | 60.0 | 413.9 | 912,483.9 | 7.71 | 7,035,250.80 |
| SEPTEMBER | 30.0 | 206.9 | 456,131.7 | 7.10 | 3,238,535.00 |
| OCT - JAN | 10.0 | 69.0 | 152,117.4 | 6.85 | 1,042,004.10 |
| TOTAL | 100.0 | 689.8 | 1,520,733.0 | | 11,315,789.90 |

Note: For comparison purposes, this table assumes the New York Bight set-aside is distributed evenly throughout the fishing year.
*Time-period allocations may differ slightly due to rounding.

Alternative F2 would provide NMFS with more flexibility, in comparison to the other alternatives, by establishing the General category time-periods, subquotas, and geographic set-asides annually via a regulatory framework action (*i.e.*, not an FMP amendment). The administrative burden would increase because the annual BFT specifications, plus the analytical documents, would be conducted annually. Plus, there would be a heightened importance to finalize the specifications prior to January 1 of each year, assuming the preferred CY/FY alternatives contained in Section 2.3.2 are implemented. Under this alternative, the industry would not have the necessary information to devise a business plan for the upcoming year prior to the start of the fishery because the time-periods and associated subquotas would be established each year. For example, each year, permit applicants may choose a quota category in which to permit their vessel, and this decision is usually based on the amount of quota and the rules and regulations that pertain to each individual permit category. As the time-periods, associated subquota allocations, and potential geographic set-asides would be established just prior to the start of the fishing season, fishermen would only have the overall General category quota allocation on which to base their decisions. There may also be positive social and economic impacts attributed to increases in a domestic quota category, time-period subquota, or geographic set-aside quota in a given year. However, the likelihood of experiencing negative social or economic impacts due to a decrease in any of these areas is equally the same.

Alternative F3, a preferred alternative, would blend aspects of alternatives F1 and F2 together to optimize the positive social and economic impacts by enhancing NMFS' flexibility to adapt to the BFT fisheries' inherent variability. This alternative would provide consistent General category time-periods and subquotas, from one year to the next, as the quota tonnage derived from the domestic quota allocations percentages and the ICCAT recommended BFT TAC would be codified in the regulatory text implementing the consolidated HMS FMP. These baseline quota amounts would change when ICCAT modifies or amends the BFT TAC recommendation. This alternative would also authorize adjustments to the General category time-periods, associated subquotas, and geographical set-asides via a regulatory framework action versus an FMP amendment, if warranted, based on changes to the ICCAT BFT quota recommendations. This balance between providing consistent baseline quota allocations and having the flexibility and ability to amend them, if warranted, in a relatively timely fashion would provide positive social and economic impacts because fishermen would be able to plan their business activities in advance while the Agency would have the flexibility to adapt to changing fishery conditions.

This alternative would also adjust the actual General category time-periods and the associated subquotas to reflect historical General category BFT allocations while incorporating recent trends in the fishery, both temporally and geographically. For instance, historically, the General category BFT fishery has been prosecuted in the summer and early fall months primarily in the waters off of New England. However, in recent years, BFT have been available in large numbers during the winter months in waters off the South Atlantic states. Therefore, this alternative would have positive social and economic impacts on the General category as a whole by providing reasonable fishing opportunities to General category BFT fishery participants over a broader geographic and temporal range when BFT are available to them, as well as providing some level of certainty as to the amount of quota that would be available for a given time-period. Any adverse social and economic impacts that may be associated with this alternative would be minor and primarily linked to the slight shifts in General category quota allocation as discussed in further detail under each subalternative.

Under these sub-alternatives, the potential gross revenues are calculated using 1999 through 2004 average monthly ex-vessel prices per pound (whole weight), the quota tonnage for each time-period (based on the preferred allocation percentages), the assumption that catch rates are consistent across time, and that each time-period subquota allocation is harvested in its designated time frame. NMFS is aware that these assumptions may not account for the variability inherent in the fishery (*i.e.*, availability of BFT, skill level of fishermen, weather conditions, etc.); the analyses, however, show the relative impacts of the various alternatives.

All of the following sub-alternatives would allow for the carryover of unharvested General category quota to the subsequent time-period allocation as stated in the No Action alternative (F1) or as stated in alternative F4. Under the alternatives, the break in fishing years would fall in the middle of the current winter fishery, *i.e.*, between December and January. NMFS discusses how this may affect quota rolling over from one time-period to another in more detail in Section 2.3.2. These alternatives also formally respond the Petition for Rulemaking submitted by the NCDMF. The Petition claims that the current General category BFT quota allocation scheme does not provide a reasonable opportunity to harvest BFT with commercial handgear off the South Atlantic coast during the winter months, thereby not ensuring fair and equitable treatment of all General category permit holders.

Subalternative F3(a) would distribute the coastwide General category quota equally, in 12.5 percent shares (Table 4.60), among the eight months that make up the General category BFT season (June-January). This subalternative would have both positive and negative social and economic impacts as it would provide some stability to the constituency by establishing a known amount of quota that would be available at the first of each month. However, if catch rates are high in the early portion of the month, these quotas could be harvested rapidly and may lead to derby style fisheries on the first of each month, which is contrary to NMFS' intent. This subalternative would formalize the General category winter BFT fishery, but would do little to recognize historical General category BFT allocations, thereby potentially excluding a group of long-time participants. This subalternative would result in positive social and economic impacts for those General category participants located in the South Atlantic region due to a 40 percent increase in available quota, compared to the No Action alternative, during the time frame of October through January. This increase in quota would equate to approximately $5.5 million in additional gross revenues for those individuals that participate in the later part of the General category season. However, those General category participants in the New England area, or those participants that pursue BFT in the summer months, might experience some adverse social and economic impacts due to the shift in quota to the later portion of the season. For instance, under this alternative, the status quo June through August time-period subquota allocation would be reduced by approximately 22.5 percent and the September time-period subquota by approximately 17.5 percent. These reductions in allocation would result in decreased gross revenues of approximately $2.8 and $1.8 million, respectively. This totals $4.6 million in losses whereas the gain above is $5.5 million. The difference of $0.9 million is derived from the different average ex-vessel prices at different times of the fishing year. This subalternative would also reduce the need for specific geographic set-asides because quota allocations would be made on a monthly basis. This subalternative would assist in distributing the General category BFT catch, temporally and geographically, which is beneficial for the collection of CPUE data and may assist in avoiding large scale landings in a constrained time frame, thus reducing market gluts.

**Table 4.60 Alternative F3(a): Gross revenues associated with the even sub-allocation of the General Category quota between the 8-month fishing season.**

| Time-Period | Percentage | Approx. Equivalent in mt* | Approx Equivalent in lb* | Average Ex-Vessel $ ('99-'04) | Approx. Gross Revenues |
|---|---|---|---|---|---|
| JUNE | 12.5 | 86.23 | 190,102.65 | 6.42 | $ 1,220,459.01 |
| JULY | 12.5 | 86.23 | 190,102.65 | 8.19 | $ 1,556,940.70 |
| AUGUST | 12.5 | 86.23 | 190,102.65 | 7.56 | $ 1,437,176.03 |
| SEPTEMBER | 12.5 | 86.23 | 190,102.65 | 7.10 | $ 1,349,728.82 |
| OCTOBER | 12.5 | 86.23 | 190,102.65 | 6.66 | $ 1,266,083.65 |
| NOVEMBER | 12.5 | 86.23 | 190,102.65 | 7.01 | $ 1,332,619.58 |
| DECEMBER | 12.5 | 86.23 | 190,102.65 | 7.70 | $ 1,463,790.41 |
| JANUARY | 12.5 | 86.23 | 190,102.65 | 7.76 | $ 1,475,196.56 |
| TOTAL | 100.0 | 689.8 | 1,521,174.0 | | $11,101,994.76 |

*Time-period allocations may differ slightly due to rounding.

Subalternative F3(b) would implement General category time-periods, and associated subquota allocation percentages similar to those contained in the 1999 FMP, but would separate the October through January time-period into three distinct time-periods of October through November, December, and January. This would establish a formal General category winter BFT fishery on which fishermen, dealers, and supporting industries could depend and plan. The General category time-period subquota allocation percentages would be adjusted slightly to incorporate the allocations in the winter months, but would still recognize the historical General category allocations during the summer and fall months (Table 4.61).

This subalternative would have positive social and economic impacts to those General category participants located in the South Atlantic region due to a 9.5 percent increase in available quota, compared to the No Action alternative, during the time frame of October through January. This increase in quota would equate to approximately $1.1 million in additional gross revenue for the later part of the General category season. However, those General category participants in the New England area, or those participants which pursue BFT in the summer months, may experience roughly equivalent adverse social and economic impacts due to the shift in quota to the later portion of the season. For instance, under this alternative, the status quo June through August time-period subquota allocation would be reduced by approximately six percent and the September time-period allocation by approximately 3.5 percent. These reductions in allocation would result in decreased early season gross revenues of approximately $0.7 and $0.4 million, respectively. These negative impacts may be mitigated by individuals traveling to where the BFT are located at any time of the season. However, NMFS has little specific information at this time regarding the costs that would be incurred due to this travel.

**Table 4.61 Alternative F3(b): Gross revenues associated with the proposed sub-allocation of the General Category quota, providing a BFT winter fishery in the South Atlantic**

| Time-Period | Percentage | Approx Equivalent in mt* | Approx Equivalent in lb* | Average Ex-Vessel $ ('99-'04) | Approx. Gross Revenues |
|---|---|---|---|---|---|
| JUNE - AUG | 54.0 | 372.5 | 821,213.5 | 7.71 | $6,331,556.09 |
| SEPTEMBER | 26.5 | 182.8 | 403,000.9 | 7.10 | $2,861,306.39 |
| OCT - NOV | 9.0 | 62.2 | 137,126.1 | 6.68 | $ 916,002.35 |
| DECEMBER | 5.2 | 35.9 | 79,145.1 | 7.70 | $ 609,417.27 |
| JANUARY | 5.3 | 36.5 | 80,467.9 | 7.76 | $ 624,430.90 |
| TOTAL | 100.0 | 689.8 | 1,520,953.5 | | $11,342,713.00 |

*Time-period allocations may differ slightly due to rounding.

Subalternative F3(c) (preferred) would implement the same time-periods as mentioned in subalternative F3(b), but would implement slightly different subquota allocation percentages for the June through August and October through November time-periods (Table 4.62). This subalternative was designed to redistribute the quota from the early time-periods to provide a winter General category BFT fishery during the months of December and January. This subalternative would reduce the allocation to the June through August time-period to a higher degree than subalternative F3(b) and increase the suballocation to the October through November time period, thus shifting more of the potentially adverse social and economic impacts to the earliest portion of the season.

This subalternative would enhance equity among regional General category participants, given that access to fish can vary considerably both temporally and geographically. Because this alternative would allocate General category quota based on a balance between historical General category BFT allocations, recent BFT landing trends, and the NCDMF Petition for Rulemaking, there would be no significant social or economic impacts to the fishery as a whole, however, there may be heighten regional or local impacts. Public comments generally support the preferred alternative to modify the General category time-periods and percentages because it ensures that fishermen in all the South Atlantic states (North Carolina, South Carolina, Georgia, and Florida’s East coast) have an opportunity to participate in this fishery. However, this subalternative would have similar positive and adverse social and economic impacts as outlined in subalternative F3(b). The adverse social and economic impacts would be shifted to the earliest portion of the fishery, where the General category subquota allocations have traditionally been the highest. This subalternative would have positive social and economic impacts to those General category participants fishing in the later portion of the season due to a 13.5 percent increase in available quota, compared to the No Action alternative, during the time frame of October through January. This increase in quota would equate to approximately $1.5 million in additional gross revenue for the later part of the General category season. However, those General category participants who pursue BFT in the summer months may experience roughly equivalent adverse social and economic impacts due to the shift in quota to the later portion of the season. For instance, under this alternative, the status quo June through August time-period subquota allocation would be reduced by approximately ten percent and the September time-period by approximately 3.5 percent. These reductions in allocation would result in decreased gross revenues of approximately $1.2 and $0.3 million, respectively, for each of these time periods.

Reallocating more quota from the June through August time-period to the later time-periods would mitigate some of these adverse social and economic impacts because the June through August subquota has the largest allocation under the status quo and the amount of quota that would be reallocated would equate to a smaller percentage of the June through August subquota in comparison to the same amount of quota being reallocated from the other time-period subquotas. This subalternative is preferred due to the balance it strikes between providing all General category BFT fishery participants an equitable opportunity to harvest a portion of the coastwide General category quota, while still recognizing the historical participation in this fishery. Any adverse social or economic impacts associated with this alternative would be minimized and may even be mitigated as fishermen may travel to the geographical location of where the BFT are located at any give time. However, as stated previously, NMFS has little specific information at this time regarding the costs that would be incurred due to this travel.

**Table 4.62 Alternative F3(c) (preferred): Gross revenues associated with the proposed sub-allocation of the General Category quota, providing a BFT winter fishery in the South Atlantic.**

| Time-Period | Percentage | Approx. Equivalent in mt* | Approx. Equivalent in lb* | Average Ex-Vessel $ ('99-'04) | Approx. Gross Revenues |
|---|---|---|---|---|---|
| JUNE - AUG | 50.0 | 345.0 | 760,587.0 | 7.71 | $ 5,864,125.77 |
| SEPTEMBER | 26.5 | 182.8 | 403,000.9 | 7.10 | $ 2,861,306.39 |
| OCT - NOV | 13.0 | 89.7 | 197,752.6 | 6.68 | $ 1,320,987.37 |
| DECEMBER | 5.2 | 35.9 | 79,145.1 | 7.70 | $ 609,417.27 |
| JANUARY | 5.3 | 36.5 | 80,467.9 | 7.76 | $ 624,430.90 |
| TOTAL | 100.0 | 689.8 | 1,520,953.5 | | $11,280,267.70 |

*Time-period allocations may differ slightly due to rounding.

Subalternative F3(d) would implement the same time-periods as described in sub-alternatives F3(b) and F3(c), but would allocate the General category time-period subquota in accordance with the NCDMF's Petition for Rulemaking (*i.e.*, 150 mt total for the months of December and January or approximately 21.7 percent of the coastwide General category quota (Table 4.63). This alternative would have a greater positive social and economic impact to General category participants in the South Atlantic region due to a 24.7 percent increase in available quota, compared to the No Action alternative, during the time frame of October through January. This increase in quota would equate to approximately $2.8 million in additional gross revenue for the later part of the General category season. However, those General category participants in the New England area, or those participants that pursue BFT in the summer months, may experience roughly equivalent adverse social and economic impacts due to the shift in quota to the later portion of the season. For instance, under this alternative, the status quo June through August time-period subquota allocation would be reduced by approximately 21.3 percent and the September time-period allocation by approximately 3.4 percent. These reductions in allocation would result in decreased gross revenues of approximately $2.5 and $0.3 million, respectively. These negative impacts may be mitigated by individuals traveling to where the BFT are located at any time of the season.

**Table 4.63 Alternative F3(d): Gross revenues associated with the proposed sub-allocation of the General Category quota, providing a BFT winter fishery in the South Atlantic.**

| Time-Period | Percentage | Equivalent in mt* | Equivalent in lb* | Average Ex-Vessel $ ('99-'04) | Gross Revenues |
|---|---|---|---|---|---|
| JUNE - AUG | 38.7 | 267 | 588,628.2 | 7.71 | $4,538,323.42 |
| SEPTEMBER | 26.6 | 183.5 | 404,544.1 | 7.10 | $2,872,263.11 |
| OCT - NOV | 13 | 89.7 | 197,752.6 | 6.68 | $1,320,987.37 |
| DECEMBER | 10.8 | 74.5 | 164,252.7 | 7.70 | $1,264,745.79 |
| JANUARY | 10.9 | 75.2 | 165,785.9 | 7.76 | $1,286,498.58 |
| TOTAL | 100 | 689.9 | 1,520,953.5 | | $11,282,818.27 |

*Time-period allocations may differ slightly due to rounding.

Alternative F4 (preferred) would clarify the procedures NMFS uses to calculate the ICCAT recommendation regarding the eight percent tolerance for BFT under 115 cm (young school and school BFT). This alternative would have slightly more positive social and economic impacts than the No Action alternative, as it would slightly increase the school size-class BFT quota by approximately 2 mt from the status quota allocation. This alternative would implement the ICCAT recommendation more accurately based on the specific language contained in the recommendation.

In response to public comment, this alternative has been slightly modified from that proposed in the draft HMS FMP. This preferred alternative would maintain, rather than remove, the North/South Angling category dividing line. This alternative may have some positive social and economic impacts attributed to more finite quota management of the recreational BFT fishery, such as NMFS being able to implement different BFT recreational retention limits by geographic area. However, NMFS would require timely BFT landings data from the recreational sector to use this management tool in real-time. If compliance with the current recreational catch monitoring programs improves, the effectiveness of this management tool would increase. Also as recreational catch monitoring programs are improved over time, the effectiveness of this management tool would also likely increase. In the meantime, public comment indicated that maintaining the North/South line would preserve the original intent to ensure reasonable recreational fishing opportunities in all geographic areas without risking overharvest of the Angling category quota.

*Conclusion*

Alternative F3, sub-alternative F3(c), and alternative F4 are the preferred alternatives under the BFT Quota Management issue. Alternative F3, would amend the management procedures used to establish and adjust the General category time-periods, associated subquotas, as well as geographic set-asides. More specifically, the detailed information regarding the management of the General category, as contained in the 1999 FMP, would be crafted to be more general in nature. The specific details pertaining to management of the General category would be relocated into the regulatory text implementing the consolidated HMS FMP. By moving the specific language from the FMP to the implementing regulations, NMFS would be able to provide consistent time-periods and subquotas, as they would be codified in the regulations, while also gaining the ability to amend these General category time-periods, subquotas, if deemed necessary, in a relative shorter time-frame.

Because ICCAT recommended annual U.S. BFT TACs tend to remain consistent for a multiple year time frame and as the General category baseline quota (calculated from the ICCAT TAC), time-periods, and associated subquotas would be codified in the implementing regulations, the annual BFT specification process would be streamlined as a result of this alternative. The General category subquota allocation percentages would be codified in whole weight, as well as in percentages, the regulatory, environmental, social, and economic analyses conducted for the consolidated HMS FMP would remain relatively consistent and would constitute the supporting documentation for future annual regulatory framework actions specifying the upcoming years BFT quotas, provided the ICCAT BFT TAC recommendation remains consistent. However, if the specific management measures contained in the regulatory text need to be changed, for instance if ICCAT amends the BFT TAC recommendation, then an appropriate analytical document (*i.e.*, EA or EIS, RIR, IRFA, etc.) would need to accompany the proposed and final rule in the regulatory amendment. These analytical documents would replace those that constitute the supporting documentation for future annual regulatory framework actions regarding BFT quota allocations. This alternative is preferred due to the balance it strikes between providing consistent baseline quota allocations and having the flexibility and ability to amend them, if warranted, in a relatively timely fashion. This alternative would also provide positive social and economic impacts to fishermen as they would be able to plan their business activities in advance while the Agency would have the flexibility to adapt to changing fishery conditions.

Sub-alternative F3(c) would remove the New York Bight set-aside allocation and divide the coastwide General category season into five distinct time-periods, June through August, September, October through November, December, and January. The time-periods, and associated subquotas, of this sub-alternative would allocate fishing privileges to further achieve optimum yield without excluding traditional participants in the fishery. Thus, this sub-alternative would establish time-period subquota allocation percentages as follows: 50 percent (June through August), 26.5 percent (September), 13 percent (October through November), 5.2 percent (December), and 5.3 percent (January). This sub-alternative is preferred because it would enhance equity among regional General category participants, given that access to fish varies considerably both temporally and geographically. This sub-alternative is also preferred because it would allocate General category quota based on striking a balance between historical General category BFT allocations, recent BFT landing trends, and the requests contained in the NCDMF Petition for Rulemaking, and there would be no significant social or economic impacts to the fishery as a whole expected as a result of this sub-alternative.

Alternative F4 would clarify the procedure for calculating the ICCAT-recommended eight percent tolerance limit on school size-class BFT for the Angling category quota to be more consistent with the actual language from the ICCAT recommendation and would result in a slight increase of the school size class BFT quota. This alternative would also maintain the North/South Angling category dividing line located at 39º 18 minutes N. latitude (Great Egg Inlet, NJ). This alternative is preferred because it would implement the ICCAT recommendation more accurately based on the specific language contained in the recommendation and it would preserve the original intent of the North/South dividing line as it would provide more equitable geographic and temporal distribution of recreational fishing opportunities by separating each

BFT size-class subquota into two geographical regions, the northern area (allocated 47.2 percent of the size-class subquotas) and the southern area (52.8 percent of the size-class subquotas).

#### *4.3.1.2 Annual BFT Management Measures*

As described in Chapter 2, the alternatives considered for amending annual BFT quota adjustment procedures are:

F5 Maintain the annual BFT quota specification process and the under/overharvest procedures within individual domestic quota categories and individual vessels in the Purse seine category (No Action)

*F6 Revise the annual BFT quota specification process to refer back to the supporting analytical documents of the consolidated HMS FMP and include seasonal management measures in annual framework actions – Preferred Alternative*

F7 Eliminate unharvested quota carryover provisions and return unharvested quota to the resource, while maintaining status quo overharvest provisions

*F8 Establish an individual quota category carryover limit of 100 percent of the baseline allocation (i.e., no more than the annual baseline allocation may be carried forward), except for the Reserve category, and authorize the transfer of quota exceeding the 100 percent limit to the Reserve or another domestic quota category, while maintaining status quo overharvest provisions – Preferred Alternative*

*Ecological Impacts*

One of the conservation and management tools recommended by ICCAT is the use of TAC quotas for a particular species. When the United States accepts an ICCAT recommendation, ATCA provides the Secretary with the necessary authority to implement these binding recommendations. However, no regulation promulgated under ATCA may have the effect of increasing or decreasing any allocation or quota of fish or fishing mortality level to which the United States agreed pursuant to a recommendation of ICCAT.

Alternative F5 (No Action) would implement regulations as outlined in the 1999 FMP. NMFS would conduct an annual rulemaking to allocate ICCAT-recommended baseline BFT quotas, adjust those baseline quotas to account for each domestic quota category’s under/overharvests that occurred in the previous fishing year, and establish the General category effort controls for the upcoming fishing year (*e.g.*, an RFD schedule). Under this alternative, NMFS would also be authorized to allocate any remaining quota from the Reserve to cover potential overharvests, consistent with the criteria described in Section 4.3.1.3. The total of the adjusted quotas and the Reserve would need to be consistent with the 20-year ICCAT Rebuilding Program for BFT. These small orders of change, quantified in either numbers of fish or in weight (mt), or time and/or location of harvest, compared to overall U.S. harvest levels as recommended by ICCAT under the 20-year rebuilding program would equate to ecological impacts that would be unlikely to be measurable given the variability in the data used to conduct BFT stock assessments. Additionally, the numbers of BFT harvested from each different size-class would remain consistent with the levels of BFT mortality used in the stock assessment. The under/overharvest accounting procedures contained in this alternative may have some minor adverse ecological impacts. Specifically, under this alternative, a domestic category could experience excessively slow catch rates in a given fishing year resulting in large amounts of unharvested quota being carried forward from one fishing year to the next, especially if this were to occur in multiple successive years. These rollovers could lead to a quota 'stockpiling' situation in one particular domestic quota category. Stockpiling quota could have implications for the 20-year ICCAT Rebuilding Plan for BFT, as that could allow for excessive pressure or harvest on a particularly sensitive year class.

Alternative F6 (preferred) would codify the ICCAT-recommended U.S. BFT TAC, as well as the domestic allocation percentages and quota equivalents of that TAC, in the regulations implementing the consolidated HMS FMP. The ICCAT BFT quota recommendation is based on the most recent stock assessment of western Atlantic BFT, which in turn incorporates the most up-to-date scientific information submitted annually by its member nations, and typically covers multiple years. This alternative would eliminate the need to allocate the baseline quota to each domestic category every year as the allocation percentages and quota equivalents (in mt) would be codified in the regulations implementing the consolidated HMS FMP, at least until ICCAT alters the U.S. BFT TAC recommendation. NMFS would conduct under/overharvest adjustments annually and may transfer quota among the categories, so long as the results of these actions are consistent with all pertinent ICCAT recommendations, especially the 20-year ICCAT Rebuilding Program for BFT. As the ICCAT-recommended U.S. BFT TAC is based on the most recent scientific data, as incorporated in the western Atlantic BFT stock assessment, and the quota allocations are TACs, NMFS does not anticipate any adverse ecological impacts from this alternative.

This alternative would maintain the default General and Angling category BFT retention limits (described in alternative F1) and would make adjustments to those limits in the annual BFT quota specifications, allowing the public an opportunity to comment on such actions. To provide maximum utilization of the General category quota, NMFS may increase or decrease the daily retention limit of large medium or giant BFT over a range of zero to a maximum of three BFT per vessel. To provide maximum utilization of the Angling category quota, NMFS may increase or decrease the retention limit for any size class BFT or change a vessel trip limit to an angler trip limit and vice versa. NMFS would base any proposed adjustments on the determination criteria discussed in Section 4.3.1.3. NMFS would also maintain the ability to alter the retention limits via an inseason action, if warranted. For further details regarding inseason actions, please see Section 4.3.1.3. These adjustments would be inextricably linked to the available BFT quota and would be consistent with all pertinent ICCAT recommendations, especially the 20-year ICCAT Rebuilding Program for BFT. As the ICCAT-recommended U.S. BFT TAC is based on the most recent scientific data, as incorporated in the western Atlantic BFT stock assessment, and the quota allocations are TACs, NMFS does not anticipate any adverse ecological impacts from adjusting daily retention limits adjustments within the scope outlined above.

Under alternative F6, NMFS may also propose a schedule of RFDs for the upcoming fishing season. Such a schedule would accompany the annual BFT specifications and provide notice of and an opportunity for the public to comment on this type of General category effort control. The number of RFDs proposed could range from zero RFDs to a large number of consecutive RFDs, blocking out weeks at a time. RFDs, in general, are designed to have positive economic and social impacts, and have neither positive nor negative ecological impacts since they only impact when and where BFT mortality occurs, and not the magnitude. The magnitude of mortality has been dictated by finite quotas established under a 20-year rebuilding plan for BFT and other recommendations by ICCAT. Regulating effort helps achieve optimum yield while considering the social and economic interests of the participants. The limited nature of these effort controls is unlikely to have any differential impacts on the life history or overall biological distribution of the western Atlantic BFT stock. However, it is possible that if too many effort controls are implemented, effort may shift to other species or the pace of the fishery could be slowed to such an extent that the full quota is not attained. This would be contrary to the consolidated HMS FMP and ATCA and any quota underage would be applied to the following year so mortality would only be deferred. Alternatively, if too few effort controls are implemented, it is possible the BFT fisheries would attain their quota rapidly and close prematurely. Fishermen may then turn to other stocks to target, particularly other HMS species, with corresponding impacts to other elements of the ecosystem. However, neither of these scenarios is expected to result from this alternative.

Alternative F7 would have more positive ecological effects, in comparison to the other alternatives, because any underharvests from one fishing year would not carry forward to the subsequent fishing year, thus eliminating the ability for any domestic quota category to ‘stockpile’ quota. Therefore, this alternative may accelerate the rebuilding plan for western Atlantic BFT, but could ultimately result in adverse ecological impacts if the United States does not fully utilize its ICCAT-allocated TAC. Because the BFT quotas are TACs recommended by ICCAT, it is possible that any unused portion of the U.S. TAC could be reallocated to another member nation. Therefore, this alternative could have some potential adverse ecological impacts in the long-term that would be associated with a reallocation of unutilized U.S. BFT quota to an ICCAT member nation that does not have comparable conservation measures to those of the United States. For instance, a portion of the U.S. BFT TAC could be reallocated to a member nation that has a higher level of interaction with protected resources or has not taken equivalent steps to minimize bycatch.

Alternative F8 (preferred) may reduce potential adverse ecological impacts as it would allow the Agency to limit the amount of unharvested quota a category could carry from one fishing year to the next. This alternative would allow NMFS to curtail excessive amounts of BFT quota from accumulating in any particular domestic quota category due to multiple successive years of underharvest and therefore, may curb the likelihood of a ‘stockpiling’ situation. This alternative would authorize NMFS to redistribute quota exceeding the 100 percent rollover cap to the Reserve or to other domestic quota categories, if deemed necessary, provided the redistributions are consistent with ICCAT recommendations and the criteria in Section 4.3.1.3. NMFS received public comment concerned about transferring quota from one category to the Reserve, which eventually may be transferred to yet another category that harvests BFT within a different size range than the original category. One metric ton of BFT equals many more fish within the school size range than one metric ton in the giant size class. Therefore, to avoid any potential adverse ecological impacts that may occur, quota origin may need to be tracked to ensure the level of mortality is consistent with those accounted for in the stock assessment. This alternative would provide reasonable fishing opportunities to harvest the

ICCAT-recommended U.S. BFT TAC as close to the timeframe it was originally intended to be harvested and may reduce the likelihood of reallocating U.S. BFT quota to another member nation that does not have comparable conservation measures (see discussion under alternative F7).

*Social and Economic Impacts*

Alterative F5 (No Action) would maintain the status quo process used to allocate the ICCAT-recommended U.S. BFT TAC domestically, accounting for annual under/overharvest, and establishing General category effort controls. This alternative is unlikely to have any substantial immediate social or economic impacts given that these processes have been in place since prior to the implementation of the 1999 FMP. However, NMFS received public comment in the past regarding the timing of annual BFT specification publication and that administrative or other delays in publishing the annual BFT specifications can have adverse social and economic impacts due to constituents inability to make informed business decisions. Under this alternative, the annual BFT quota specifications would establish baseline domestic quota category allocations, as well as adjust those allocations based on the previous years under/overharvest. Any delay in publishing the annual BFT quota specifications would prolong the establishment of a baseline quota in any of the domestic categories.

Alternative F6, a preferred alternative, would have slightly more positive social and economic impacts, in comparison to alternative F5, as each baseline domestic quota category allocation, quantified in metric tons (not just the percentage of the U.S. BFT TAC) would be codified in the regulatory text implementing the consolidated HMS FMP. Therefore, each established domestic user group would have a quantifiable amount of quota available for harvest at the start of each fishing year (Table 4.64) and the filing and publication of the final annual BFT specifications would not be required to establish the baseline quotas. These baseline quotas would remain consistent from one year to the next, until ICCAT amends the recommendation regarding western Atlantic BFT TACs. If and when ICCAT amends its recommendation regarding western Atlantic BFT TACs, NMFS may need to undertake rulemaking to analyze the impacts associated with the revised recommendation and would codify the results, as they apply to each domestic quota category allocation, in the regulations. This alternative would still require NMFS to conduct an annual rulemaking to account for the previous years under/overharvest, but would provide some level of stability regarding baseline quota availability for each fishing year. This alternative would also establish General category effort controls and establish daily retention limits for the Angling and General categories and any associated time frames in the annual framework action.

This alternative would maintain the default General and Angling category BFT retention limits and would propose adjustments to those limits in the annual BFT quota specifications to provide notice of, and an opportunity for the public to comment, on these sort of actions. To provide maximum utilization of the General category quota, NMFS may increase or decrease the daily retention limit of large medium or giant BFT over a range of zero to a maximum of three BFT per vessel. To provide maximum utilization of the Angling category quota, NMFS may increase or decrease the retention limit for any size class BFT or change a vessel trip limit to an angler trip limit and vice versa. NMFS would base the proposed adjustments on the determination criteria discussed under Section 4.3.1.3 and would maintain the ability to alter the retention limits via an inseason action, if warranted. For further details regarding inseason actions, please see Section 4.3.1.3.

Under this alternative, NMFS may propose a schedule of RFDs that may be implemented for the upcoming fishing season. Such a schedule would accompany the annual BFT specifications and provide notice of, and an opportunity for the public to comment on, this type of General category effort control. The proposed RFD schedule could range from zero RFDs to a large number of consecutive RFDs, blocking out weeks at a time. In the past, when catch rates have been high, implementing more RFDs has had positive economic impacts by avoiding market gluts and providing access to higher quality fish later in the season. Positive social impacts have also occurred as fishermen have commented that knowing the exact schedule of RFDs prior to the season facilitates planning and scheduling of trips. However, if catch rates are slow and a large amount of RFDs hinder the ability to harvest a time-period subquota, waiving RFDs in mid-season can cause confusion and disrupt fishermen's activity and, although information regarding the canceling is widespread over various electronic and paper media, there may be some negative social impacts as a result. Under this alternative, NMFS would maintain the authority to add or waive RFDs if deemed necessary.

To streamline the annual rulemaking, NMFS would analyze baseline allocations and the range of possible under/overharvests that could occur from the previous years fishing activity (see alternative F8) in the analytical supporting documents of the consolidated HMS FMP. This alternative would have positive social and economic impacts to the domestic BFT fishery as a whole by allowing commercial and recreational BFT fishery participants to make informed decisions on how best to establish a business plan for the upcoming season as well as helping to achieve optimum yield from the BFT fishery.

Alternative F7 would have the most adverse social and economic impacts of all the alternatives considered for this issue. Under this alternative, NMFS would not carry forward unharvested quota from one fishing year to the next. This could result in a perception that domestic quota categories are being penalized for not harvesting their allocated quota in the time provided and may lead to derby style fishing, causing vessels to operate in less than optimal conditions. This alternative could also result in a domestic quota category not receiving a quota transfer from another domestic quota category with large amounts of underharvest to assist in covering an overharvest situation, which could result in quota deducted from that category in the following year. This could result in reduced fishing opportunities, income, and angler consumer surplus for the commercial and/or recreational fleet, as well as the businesses that support those BFT fisheries. This alternative would have adverse social and economic impacts attributed to potential BFT quota reallocations at the ICCAT level, as discussed in the ecological impacts section of this issue.

Alternative F8, a preferred alternative, would have both slightly positive and negative social and economic impacts on BFT fishery participants. Under this alternative, each domestic quota category would be limited in the amount of unharvested quota carried forward from one fishing year to the next. This limit, or cap, would in turn limit the amount of revenue each domestic quota category could generate to no more than the value associated with double the baseline allocation (Table 4.64). These potential adverse economic impacts may be mitigated, overall, by reallocating the tonnage that exceeds the 100 percent cap to the Reserve or to another domestic quota category using the criteria stipulated in Section 4.3.1.3. In addition, this alternative would not preclude the NMFS from transferring additional quota from the Reserve back to a category that has reached the rollover limit via an inseason action, if warranted.

**Table 4.64 Alternative F8: Gross revenues associated with the proposed rollover cap of 100 percent of the baseline quota allocation.**

| Category | Baseline quota allocation * | Roll-over allotment | Total Potential Annual Quota (mt) | Total Potential Annual Quota (lb) | Average Ex-vessel price (99-04) | Total Potential Gross Revenues |
|---|---|---|---|---|---|---|
| General | 689.8 | 689.8 | 1,379.6 | 3,041,466 | 7.17 | $21,807,311.22 |
| Harpoon | 57.1 | 57.1 | 114.2 | 251,765 | 7.17 | $1,805,155.05 |
| Purse Seine | 272.4 | 272.4 | 544.8 | 1,201,066 | 4.99 | $5,993,319.34 |
| Longline | 118.6** | 118.6** | 237.2 | 522,931 | 6.18 | $3,231,713.58 |
| Trap | 1.5 | 1.5 | 3.0 | 6,614 | N/A | N/A |
| Angling | 288.6 | 288.6 | 577.2 | 1,272,495 | N/A | N/A |

*Based on current ICCAT-recommended U.S. BFT TAC
** Does not include the NED Statistical set-aside annual allocation of 25 mt.
N/A = Not Available

*Conclusion*

Alternatives F6 and F8, are the preferred alternatives because F6 would revise the annual BFT quota specification process so the supporting analytical documents of the consolidated HMS FMP would be referred back while F8 would establish the authority to implement an individual quota category carryover limit of 100 percent of the baseline allocation, except for the Reserve category, and authorize the transfer of quota exceeding the 100 percent limit to the Reserve or another domestic quota category, while maintaining status quo overharvest provision. Under alternative F6, each baseline domestic quota category allocation, quantified in metric tons (not just the percentage of the U.S. BFT TAC) would be codified in the regulatory text implementing the consolidated HMS FMP. Therefore, each established domestic user group would have a quantifiable amount of quota available for harvest at the start of each fishing year and the filing and publication of the final annual BFT specifications would not be required to establish the baseline quotas. These baseline quotas would remain consistent from one year to the next, until ICCAT amends the recommendation regarding western Atlantic BFT TACs, at which time the impacts to the new recommendation would need to be analyzed. Alternative F8 would allow NMFS to curtail excessive amounts of BFT quota from accumulating in any particular domestic quota category due to multiple successive years of underharvest and therefore, may curb the likelihood of a 'stockpiling' situation.

These alternatives were preferred because they would provide participants in the BFT fishery a timely and stable baseline quota allocation from one year to the next, the Agency the ability to address under/overharvests from the previous year, the ability to establish the General category effort controls as well as recreational and commercial handgear daily retention limits for the upcoming season, and streamline the annual rulemaking process. Additionally, they would provide NMFS the authority to implement a cap on the amount of quota that a category may carry forward from one fishing year to the next would allow NMFS to manage the harvest of BFT with more finite precision and minimize the occurrence of 'stockpiling' in any one quota category.

#### *4.3.1.3 Inseason Actions*

As described in Chapter 2, the alternatives considered for amending inseason action procedures are:

F9 Maintain inseason action procedures (No Action)

*F10 Revise and consolidate criteria considered prior to performing inseason and some annual BFT management actions – Preferred Alternative*

F11 Eliminate BFT inseason actions

*Ecological Impacts*

Alternatives F9 and F10 would both authorize NMFS to perform inseason adjustments which may include, but would not be limited to, quota transfers between categories, adjustments to daily retention limits, and interim closures of a fishery when deemed necessary. Under these alternatives, NMFS would consider numerous criteria in making a determination, consistent with the objectives of the ICCAT recommended 20-year rebuilding plan, Magnuson-Stevens, ATCA, and the consolidated HMS FMP. As the criteria outlined in this section encompass the objectives of the consolidated HMS FMP, NMFS anticipates neutral ecological impacts from these two alternatives. The consolidation of the criteria considered prior to implementing an inseason adjustment was generally supported by the public comments on the Draft Consolidated HMS FMP.

Under alternative F11, NMFS would not perform any inseason actions, which could result in some negative ecological impacts. For instance, NMFS would not curtail daily retention limits or impose interim closures if BFT catch rates were high, which could lead to premature closures or overharvests in a particular domestic quota category, thus leading to negative ecological impacts. Conversely, catch rates may be slow, which could lead to unharvested quota and excessive quota rollovers from one year to the next, or in the case of General category subquotas, from one time-period to the next, which could lead to a ‘stockpiling situation and therefore potential adverse ecological impacts.

*Social and Economic Impacts*

Under alternatives F9 and F10, NMFS would conduct inseason management actions, consistent with the determination criteria described in Section 4.3.1.3, which would allow for the flexibility to better meet the objectives of the consolidated HMS FMP, ICCAT recommendations, Magnuson-Stevens Act, and ATCA in a more responsive fashion. Both of these alternatives would allow the Agency to adapt management measures to the inherent variability in the BFT fishery, and thus provide for maximum utilization of the BFT quota. NMFS would have the ability to adjust the daily retention limits in the domestic quota categories with the highest participation rates, namely the Angling and General categories, and to provide fishery participants an opportunity to harvest a portion of their respective quotas while those fish are available, thereby providing reasonable fishing opportunities to those participants. These alternatives would also allow the Agency to curtail effort, if warranted, either by restricting retention limits or imposing an interim closure to help facilitate reasonable fishing opportunities for all participants across temporal and geographic differences.

For instance, NMFS may adjust the General category daily retention limit between a range of zero and three BFT per vessel per day/trip. When catch rates are low, as they have been in the early portion of the season over the last few years, a liberalized retention limit of two or three fish may have positive social and economic impacts on a vessel that is able to harvest multiple fish, due to the limited supply of U.S. fish on the market at that time. Some of the highest ex-vessel prices have occurred during this time-period when catch rates were slow. Providing a multiple fish retention limit may also assist in offsetting operating costs when there is a long steam time to and from the fishing grounds. Fishermen are able to remain on the fishing grounds longer, and in some cases overnight, instead of running long distances on a daily basis if they are allowed to retain multiple fish. Having the ability to liberalize the daily retention limit also has some potential adverse social and economic impacts as well. For example, if catch rates were to increase dramatically over a short period of time while the retention limits were set at the upper end of the allowable range, large numbers of BFT could be landed in a short time period, thus flooding the market and depressing ex-vessel prices, and harvesting the quota at an accelerated rate. Another potential adverse impact linked to having the ability to adjust these retention limits is the inability to accurately forecast when and for how long the adjustments should be effective. Therefore, NMFS must remain diligent in monitoring the BFT fishery as close to real time as possible.

In regard to the Angling category retention limits, both positive and negative social and economic impacts could be associated with having the flexibility to adjust them inseason, similar to the General category. There may be positive impacts associated with liberalizing the daily retention limits, either by angler, by vessel, or vessel type, due to the enhanced fishing opportunities that would be associated with the increase in retention limits. In past years, NMFS has received comments from the HMS CHB sector that increased retention limits provide additional incentives for individuals to book charters, because the charter party would have the opportunity to retain more fish for the same amount money spent on the charter itself. For those privately owned and operated recreational vessels, a liberalized retention limit also provides some additional incentive to target BFT, due to an increase in Angler Consumer Surplus (ACS) by increasing the amount of BFT that could be retained in relation to the costs incurred running offshore (*i.e.*, in terms of fuel, bait, food, etc.). Potential adverse impacts may be associated with lowering/constraining retention limits or imposing an interim closure to ensure anglers in different temporal or geographical areas are not precluded from a reasonable opportunity to harvest a portion of the Angling category quota. Another potential adverse impact related to having the ability to adjust these retention limits is the inability to accurately predict catch rates and in turn forecast when and for how long the adjustments should be effective. This is especially true when charter trips are booked at a time when more liberal retention limits are in place but are restricted prior to the actual date the trip is taking place. Therefore, NMFS must remain diligent in monitoring the BFT fishery as close to real time as possible.

Therefore, both alternatives F9 and F10 could have both positive and negative economic and social impacts on BFT fishery participants due to the ability to adapt regulations inseason to meet the objectives of the consolidated HMS FMP and the inherent inability to foresee when a change should take place. Alternative F10 would have slightly more positive economic and social impacts as the criteria NMFS would consider when making an inseason action would be consolidated and consistent, regardless of what type of inseason action is under consideration. This consolidation would minimize confusion regarding how NMFS came to a decision, and thereby provide additional transparency to the management process.

Alternative F11 would constrain NMFS' ability to adjust management actions affecting the BFT fishery and could impact the ability to fully meet the objectives of the consolidated HMS FMP, one of which is providing reasonable fishing opportunities. Fishery participants would experience positive social and economic benefits by knowing that quota allocations and daily retention limits were to remain stable throughout the entire season, which would aid in planning fishing activities. However, participants would also experience adverse social and economic impacts attributed to the limitations imposed on NMFS in providing for maximum utilization of the BFT quota spread over the longest period of time (*i.e.*, limits would need to be more restrictive than under alternatives F9 and F10 to ensure quotas were not exceeded).

*Conclusion*

Western Atlantic BFT are overfished, and one of the main objectives of the consolidated HMS FMP is to end overfishing and rebuild overfished stocks, while providing reasonable fishing opportunities to harvest the limited quota that is available under the BFT rebuilding plan. Consolidating and refining the criteria that NMFS would consider prior to conducting any inseason, and some annual, actions would assist in meeting the consolidated HMS FMP's objectives in a consistent manner, providing reasonable fishing opportunities, increasing the transparency in the decision making process, and balancing the resource's needs with users' needs. Therefore, alternative F10 is the preferred alternative for this issue.

### 4.3.2 Timeframe for Annual Management of HMS Fisheries

As described in Chapter 2, the alternatives considered to change the annual management timeframe for HMS fisheries are listed below, and depicted in Table 4.65:

G1 Maintain the current fishing year for all HMS (No Action)
G2 *Shift the fishing year to January 1 – December 31 for all HMS - Preferred Alternative*
G3 Shift the fishing year to June 1 – May 31 for all HMS

**Table 4.65 Fishing years by HMS proposed for Alternatives G1-G3.**

| **HMS** | **Fishing Year** | | |
|---|---|---|---|
| | **Alternative G1 (No Action)** | **Alternative G2 (Preferred)** | **Alternative G3** |
| **Tuna** | June 1 – May 31 | January 1 – December 31 | June 1 – May 31 |
| **Sharks** | January 1 – December 31 | January 1 – December 31 | June 1 – May 31 |
| **Swordfish** | June 1 – May 31 | January 1 – December 31 | June 1 – May 31 |
| **Billfish** | June 1 – May 31 | January 1 – December 31 | June 1 – May 31 |

*Ecological Impacts*

The three alternatives for changing the annual management timeframe for HMS fisheries are given in Table 1. This action would be largely administrative and each alternative considered would have a minimal ecological impact. From a long-term perspective, the amount of fish harvested and resultant fishing effort would not be expected to change overall. However, there could be some short-term, minor ecological impacts.

The migratory nature of HMS stocks results in seasonal availability in different geographic regions. If a quota is harvested before the end of a fishing year, the geographic area where the fish would normally be located at the end of the fishing year would be expected to experience less fishing effort. Thus, if sensitive life stages such as spawning adults or limited year classes are concentrated in geographic areas that are not fished because a quota is harvested, in general, the stock could experience a positive impact. The converse could also hold true – if a sensitive year class or life history stage were concentrated in a geographic area open to fishing at the beginning of a fishing year, in general, negative impacts to the stock could occur.

HMS stocks that are limited by quotas (BFT, albacore tuna, swordfish, sharks) or subject to catch limits (white and blue marlin) could potentially be impacted in this way. However, for each of these fisheries, there are mitigating circumstances that minimize the potential for these impacts. Neither the albacore tuna nor the swordfish fisheries have been harvesting the entire available quota, so these fisheries have remained open throughout the season. A change in the fishing year should have no impact unless there are changes in these fisheries that would increase landings. BFT, swordfish and sharks are highly regulated with temporal and/or geographic subquotas, intended in part to spread these fisheries out over the entire fishing year and range of the fishery. In addition, the sensitive life stage of spawning BFT in the Gulf of Mexico is already highly regulated.

For blue and white marlin, the ICCAT 250 marlin catch limit proposed to be codified under preferred Alternative E6 has rarely been reached historically. Thus, barring unanticipated and significant changes in recreational fishing effort or practices, these fisheries are expected to continue throughout the year without the need for inseason management actions to increase the minimum size limit, and/or implement catch-and-release restrictions, as per preferred alternative E6. In the unlikely event that a threshold for implementation of these management measures is reached, there is little information available to show that sensitive life stages or year classes of these species are more or less available in different geographic regions. Thus, NMFS does not expect any negative or positive impacts to target species from this perspective as a result of any of the alternatives (G1-G3) considered for this action.

In addition, since this action is largely administrative, few impacts are expected to non-target species, including finfish and protected species, and no impacts would occur to EFH. There is a limited potential for some minimal reduction in fishing effort or minimal shift in fishing effort from targeting marlin to targeting some other species as a result of any of the Alternatives (G1-G3) in combination with implementing a management measure under Alternative E6. If an overall reduction in fishing effort occurred, a small positive ecological impact to non-target species could result under Alternatives G1-G3. This potential minimal positive ecological impact would be expected to be slightly higher under Alternative G2 (preferred alternative) since the number of days that management measures under Alternative E6 are projected to be in place, and thus the number of days that effort could be reduced, would be greater (*e.g.* August 22- December 31 under Scenario 2 or August 25 – December 31 under Scenario 3) than for Alternatives G1 and G3 (*e.g.*, May 3-31 under Scenario 2 or May 12-31 under Scenario 3). See the discussion of social and economic impacts under Alternative E6 in Section 4.2.3 for a description of the scenarios and analyses.

Some small negative impacts could result for non-target species from a shift in fishing effort under each of the Alternatives (G1-G3) in combination with Alternative E6; however, the species and amount of impacts are currently not quantifiable. Contrary to the previous discussion, impacts could be slightly higher to non-target species if a shift in effort to non-HMS species occurred under Alternative G2, since the management measures are expected to be in effect for a longer duration. However, for both these discussions, it is important to remember that it is impossible to predetermine fisherman behavior and that overall impacts are not quantifiable at this time, but are expected to be small.

Alternative G2 would also include implementation of an abbreviated fishing year for BFT and swordfish, which would provide the entire 2007 quotas for harvest from June-December of 2007 (Table 4.67). This compressed fishing year differs from the compressed fishing year described in the Draft HMS FMP by the year in which it would occur. Because the comment period was extended, the compressed fishing year would occur in 2007 rather than 2006 as described in the Draft HMS FMP. The compressed fishing year would allow the ability to harvest quota that is usually harvested from January through May during the period June through December. As noted above, this would be in addition to what is usually harvested from June through December. Although it may appear that fishing effort would be elevated during this compressed six month fishing year as compared to a twelve month fishing year, NMFS expects that this will not be the case. This is illustrated by the average cumulative percentage of BFT that is usually commercially harvested from January through May, which is only 4.3 percent of the overall annual commercial landings (in number of fish, Table 4.66). In addition, the annual quota specification process for both swordfish and BFT allow a roll-over of any unharvested quota from year to year. There could be some small increase in adverse ecological impacts to non-target species from the small increase in fishing effort that could accompany the additional 4.3 percent of BFT quota harvested during the last six months of a calendar year, but it is unlikely that these impacts would vary perceptibly from those that would occur during a twelve month fishing year. Since swordfish fisheries are currently not harvesting the entire annual swordfish quota, the availability of additional quota during a certain time-period would only have minimal effects.

**Table 4.66 Average number of commercially harvested BFT by month for 1999-2004. Data source: NERO BFT landings database.**

| | MONTH (1999-2004) | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | **Jan** | **Feb** | **Mar** | **Apr** | **May** | **Jun** | **Jul** | **Aug** | **Sep** | **Oct** | **Nov** | **Dec** | **Total** |
| **No. of Fish** | 66 | 26 | 39 | 50 | 41 | 222 | 547 | 1014 | 1579 | 1214 | 126 | 311 | 5235 |
| **% by Month** | 1.3 | 0.5 | 0.7 | 1.0 | 0.8 | 4.2 | 10.4 | 19.4 | 30.2 | 23.2 | 2.4 | 5.9 | 100 |
| **% Cum.** | 1.3 | 1.8 | 2.5 | 3.5 | 4.3 | 8.5 | 18.9 | 38.3 | 68.5 | 91.7 | 94.1 | 100 | 100 |

Similarly, Alternative G3 would require a bridge period from January 1, 2008 through May 31, 2008 for sharks, as the shark management cycle would change to a fishing year under this non-preferred alternative. The bridge period would require that the 2007 quota for sharks be stretched to cover an additional six months. This could result in small positive ecological impacts for sharks on a short-term basis, since the overall harvested quota during calendar year 2007 would be slightly reduced. In addition, Alternative G3 would include consideration of shark pupping seasons during development of new quota trimesters in order to avoid negative ecological impacts. A small reduction in directed shark fishing effort could also result in a small reduction in adverse ecological impacts to non-target species in the form of bycatch, but some impacts to finfish could increase if fishing effort were shifted to other species.

*Social and Economic Impacts*

The "No Action" alternative (G1) would maintain the fishing years for all HMS species that are currently in place (Table 4.65). This alternative is expected to maintain the current level of compliance with regulations and minimize short-term constituent confusion since nothing would change. In addition, Alternative G1 would not result in any anticipated disruption to any of the HMS markets.

Alternative G1 would maintain the current annual shark management cycle, as established in the first shark FMP (1993). If ICCAT should become more involved in shark management, Alternative G1 would provide consistent timing for U.S. domestic and international shark management programs since ICCAT manages on a calendar year cycle. However, this current management regime may be slightly more arduous for fishermen targeting more than one HMS in the long term since sharks are managed on a different timeframe than other HMS, and fishermen would have to be familiar with several administrative calendars including more than one management cycle.

Alternative G1 would continue to allow approximately six months between the annual adoption of ICCAT recommendations (typically in November) and initiation of the fishing year for tuna, swordfish, and billfish on June 1. This six month window was intended to provide time to implement necessary changes to domestic management measures to comply with international obligations. It also allowed time for the affected fisheries to anticipate changes to the management program and adjust fishing activities as needed. However, under this "No Action" alternative, U.S. domestic fishery reporting occurs on a June 1 – May 31 fishing year basis for tunas, swordfish, and billfish, while most ICCAT nations report on a calendar year basis. This situation results in complex U.S. reports to ICCAT, with a confusing structure of analyses in the U.S. National Report. Due to the complexity in reports to ICCAT, the United States' negotiating position during international compliance reviews may be weakened.

As described previously under the ecological impacts section, when a fishery has a finite quota or catch limit, its start date (as well as other factors) can impact quota availability during periods of peak market demand and effort, and the availability of quota for fisheries that occur later in the season. For example, maintaining swordfish management with a June 1 start date would ensure the availability of ample quota for harvest during the summer market. However, since the U.S. fishery is not currently harvesting its full quota, ample swordfish quota is expected to be available year-round. BFT and sharks are highly regulated with subperiods and subquotas which greatly reduce the potential for negative impacts to fisheries at the tail end of the season.

As described previously, the only quota/catch-limited fishery that could potentially be impacted by harvesting the quota/reaching a catch limit is the fishery for white and blue marlin under the ICCAT 250 limit (Alternative E6). Socio-economic impacts to Atlantic billfish fisheries as a result of moving to a calendar year management cycle (Alternatives G1 and G3) would vary slightly depending upon the management measures chosen for the directed billfish fishery (Section 4.2.3). Specifically, each option under Alternative E6, which would codify an ICCAT-recommended recreational landings limit for white and blue marlin, could result in minor to moderate negative impacts to billfish fisheries that occur at the tail-end of the management cycle. Fisheries and tournaments for billfish that occur early in the fishing year should have sufficient quota available, but tournaments scheduled for later in the fishing year could be negatively impacted if a management threshold is reached and restrictions are implemented before the tournaments occur. As discussed under Alternative E6, once activity within the fishery indicates that more restrictive management measures are necessary (*i.e.*, a management threshold for action is achieved), a restrictive measure would be triggered which would impact marlin fishing for the rest of the year (management period). Discussion in Section 4.2.3 under Alternative E6 explains potential impacts to billfish fisheries managed under a fishing year (*i.e.*, Alternatives G1 and G3) for three scenarios, briefly summarized below. Please see Section 4.2.3 for the full discussion of this analysis. As discussed in Section 4.2.3, historical marlin landings rates show that it is unlikely that the 250 marlin limit will be reached, or that any inseason management actions will be necessary.

Under Scenario 1, when the threshold for inseason management action is not achieved, there would be no management action and, as a result, no impact. In Scenario 2, the threshold for an inseason minimum size increase is achieved. During a fishing year management cycle, inseason size limit increases were projected to potentially occur on May 3. This would leave 28 days of fishing that would operate under an increased size limit for blue and/or white marlin, as determined by NMFS, and could impact approximately 25 tournaments (see Section 4.2.3 for more detail). Under Scenario 3 for a fishing year management cycle, a catch and release fishery was projected to be implemented on May 12, leaving 19 days left in the season and the potential closure of approximately one tournament (see Section 4.2.3 for more detail).

The preferred alternative (G2) would manage all HMS species on a fishing year cycle from January 1-December 31 (calendar year). This would maintain the status quo in the shark management year cycle established in the first shark FMP (1993). Thus, Alternative G2 would not be anticipated to have any social or economic impact on the shark fishery because it currently operates on a calendar year basis.

Use of a consistent calendar year across HMS fisheries would create a less complex management regime for all constituents, and as a result, could potentially increase compliance. In particular, this alternative would reduce confusion overall for constituents participating in a combination of HMS fisheries, although initially there could be some short-term confusion as tuna, swordfish, and billfish quotas and annual Atlantic tunas, HMS CHB, and HMS Angling vessel permits are adjusted to a calendar year basis.

ICCAT recommendations become effective six months after they are adopted. In most cases, this would be in May of the year following the November ICCAT meeting. Thus, Alternative G2 may result in some negative social and economic impacts if ICCAT-related regulations are not in place prior to the start of the fishing year. Since swordfish and billfish landings are relatively low for the first few months of the calendar year, these fisheries would not be impacted, but the January BFT fishery may be over before any changes to the regulations as a result of ICCAT recommendation are implemented. This could negatively impact constituents participating in the January fishery because any ICCAT recommendations with positive impacts may not be in place yet. Conversely, ICCAT recommendations with negative impacts may not be in place, either. Setting annual quotas and other fishery specifications on a multi-year basis, as preferred for the BFT fishery in Section 2.3.1.2, and re-allocating the BFT subquota time-periods (Section 2.3.1.1) could mitigate the potential negative impacts.

Alternative G2 would establish consistent management year cycles for U.S. domestic and international (ICCAT) management programs, which would reduce the complexity of U.S. reports to ICCAT and create more transparent analyses in the U.S. National Report. Reducing complexity in reporting to ICCAT would strengthen the United States' negotiating position during international compliance review.

An abbreviated 2007 fishing year, from June 1, 2007 through December 31, 2007, would be necessary to transition BFT and swordfish from the current fishing year to a calendar year. A transition fishing year is not necessary for marlin since a quota/catch limit is not currently codified, and the calendar year management cycle for marlin would be codified for the first time on January 1, 2007. The Draft Consolidated HMS FMP stated that the abbreviated fishing year for BFT and swordfish would occur in 2006; however, since the initial comment period for this action was substantially extended, it is necessary to shift the abbreviated fishing year from 2006 to 2007 in the final action.

The 1999 FMP switched management of Atlantic tunas and billfish from a calendar year to a fishing year by stretching the 1998 BFT quota through the entire calendar year of 1998 and on through to May 31 of 1999 (Table 4.67). Likewise, a 1996 action shifted swordfish from a calendar year to a fishing year by stretching the 1995 swordfish quota through to May 31, 1996 (61 FR 27304). Thus, NMFS believes it is appropriate to use the full ICCAT 2007 BFT and swordfish quotas during the 2007 abbreviated fishing year. The quotas for these fisheries would be established by the specification process in a separate rulemaking action.

Since BFT and swordfish fisheries are already strictly managed with seasons, size limits, and subquotas, any general impacts as a result of the abbreviated fishing year are expected to be minor. NMFS anticipates minor positive socio-economic impacts to BFT fisheries specifically from the abbreviated fishing year. Having access to the full 2007 quota within a seven month time period could provide a small economic benefit to all BFT fisheries, and may offset any negative socio-economic impacts that occurred when these fisheries were previously shifted from a calendar year to a fishing year and annual quotas were stretched to last 18 months (Table 4.67). In addition, as mentioned under the ecological impacts section, the vast majority of the BFT quota is harvested during June through December (Table 4.66), and any quota that is not harvested during the abbreviated fishing year can be rolled over into the following year. Impacts to swordfish fisheries are expected to be less since swordfish fisheries have not been fully harvesting the entire annual quota in recent years.

**Table 4.67 Graphic representation of the distribution of U.S. domestic BFT quota by year.**

| ICCAT Quota Yr* | Jan | Feb | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov | Dec |

| 2008 | | | | | | | | | | | | |
| 2009 | | | | | | | | | | | | |

*ICCAT Quota yr. = the year following the annual special meeting of ICCAT (usually held in November).

Overall socio-economic impacts to BFT fisheries from Alternative G2 are anticipated to be minimal. As discussed earlier, sectors of the BFT fishery are highly regulated, and time-period subquota allocations and inseason management measures are used to distribute the quota throughout the fishing year, based on guidelines established at 50 CFR 635.27 and 635.28. These guidelines include consideration of the ability of fishery participants in all geographic areas to participate in the fishery; thus, these regulations minimize any potential negative impacts to fisheries at the tail-end of the management cycle. Under the current regulations, the sub-allocation for the winter General category fishery extends between two calendar years from October to January (see Section 2.3.1.1, Alternative F1), and thus an adjusted time-period subquota is necessary to work with this alternative. The subalternatives under Alternative F3 (Section 2.3.1.1) for the BFT fishery address this concern by providing separate time period subquotas for December and January.

During the public comment period, several commentors expressed concern about the effect of a calendar year management cycle on the availability of General category quota rollover from the previous calendar year during the January portion of the south Atlantic fishery. Under changes to the BFT management program included in this Consolidated HMS FMP, the January subperiod would be provided with a quota of 5.3 percent of the annual ICCAT allocation. The HMS regulations at 50 CFR 635.27 state that NMFS will adjust General category subperiod quotas based on under- or overharvest during the previous subperiod. However, the concern relates to the rollover of under- or overharvest from one subperiod to the next between fishing years. The situation of having an active fishery occurring across the change of quota years did not occur prior to the 1999 FMP, which originally adjusted the BFT fishery to a fishing year management cycle. There are several potential scenarios that could occur regarding the disposition of carryover of any under or overharvest that accrues during the December subperiod. In the first scenario, any under or overharvest could be fully rolled over into January of the following fishing year in addition to the baseline 5.3 percent. Under this scenario, the entire underharvest would be added to the January subperiod quota, or the entire overharvest would be subtracted from the subperiod quota. In another potential scenario, 5.3 percent of the under- or overharvest would be applied to the January subperiod in addition to the baseline 5.3 percent. In a third scenario, no under- or overharvest would be applied in addition to the January subperiod 5.3 percent allocation. NMFS will work with the affected constituents through the annual BFT specification process to determine the most appropriate approach based on constituent needs and Federal requirements.

Socio-economic impacts to Atlantic billfish fisheries as a result of moving to a calendar year management cycle (Alternative G2) would vary slightly depending upon the management measures chosen for the directed billfish fishery, similar to the discussion regarding socio-economic impacts from the fishing year management cycle addressed previously. These impacts are addressed in detail in Section 4.2.3, and a brief summary is included here. Each option under preferred Alternative E6, which would codify an ICCAT-recommended recreational landings limit for white and blue marlin, could result in minor to moderate negative impacts to billfish fisheries that occur at the tail-end of the calendar year management cycle, if recreational landings substantially increase from current levels. Fisheries and tournaments for billfish that occur early in the calendar year should have sufficient catch available, but tournaments scheduled for later in the calendar year could be negatively impacted if a management threshold is reached and restrictions are implemented before the tournaments occur. As indicated in Section 4.2.3, available historical data indicate that it is unlikely that the United States will achieve the 250 limit, and thus unlikely that any of the potential impacts would occur.

The same three scenarios discussed previously under the fishing year management cycle were analyzed to estimate impacts during a calendar year management cycle (see Section 4.2.3 for detailed information). Under Scenario 1, when the threshold for inseason management action is not achieved, no impacts are anticipated. Under Scenario 2, the threshold for an inseason minimum size increase is projected to occur on August 22 and would be expected to be in place for the remainder of the calendar year. Since the inseason action would be in place for a longer period of time under a calendar year management cycle than under a fishing year management cycle, any adverse impacts would be expected to be larger for a calendar year. Under Scenario 3, catch and release fishing was projected to be reached on August 25. Under the assumptions of the analysis, this could potentially result in cancellation of a maximum of four tournaments. See Section 4.2.3 for a full discussion of this analysis.

Alternative G3 would establish a June 1 – May 31 fishing year management cycle for all HMS species (Table 4.65). As with Alternative G2, Alternative G3 would establish a consistent management cycle for all HMS fisheries, resulting in a less complex management regime for all constituents. In particular, this alternative would reduce confusion for constituents participating in a combination of HMS fisheries. While initially there could potentially be short-term confusion as the shark quotas, trimesters, and permits are adjusted to a fishing year basis, overall the HMS management regime would be less complex. A bridge period, from January 1, 2007, through May 31, 2007, would be established to transition the Atlantic shark fishery from a calendar year to a fishing year. Establishing consistent management cycles for all HMS fisheries would simplify the regulations, making them easier to understand and potentially increasing compliance.

In general, Alternative G3 would have the same impact to the seasonal availability of quota for tunas, swordfish, or billfish fisheries and tournaments as the No Action alternative, since there would be no change to the management cycle for these species. In addition, maintaining the current start dates for the tunas, swordfish, or billfish fisheries would not result in any anticipated disruption in any of these current markets or fishing activities. Alternative G3 could result in some short-term negative economic impacts as shark wholesale and retail markets adjust to the potential disruption in catch rates resulting from the shift to a fishing year and new trimesters.

Under Alternative G3, U.S. domestic fisheries data would be managed on a fishing year basis while most ICCAT nations report on a calendar year basis. ICCAT may become more involved in shark management in the future, at which time, if Alternative G3 is selected, the HMS management cycle for all fisheries would be inconsistent with ICCAT's calendar year reporting. The inconsistent management timeframe would make the structure of analyses in the U.S. National Report confusing and less transparent. The basis for taking assertive action during the international compliance review may be compromised by the inability to interpret the United States' compliance from its own report.

On a fishing year management cycle, approximately six months are available between the adoption of ICCAT recommendations and initiation of the fishing year. Thus, it is more likely that NMFS could complete the regulatory implementation process before the start of the fisheries. As in the current tuna, swordfish and billfish fisheries, NMFS would have six months to implement necessary changes to domestic management measures to comply with international obligations, and the fishery would be able to anticipate changes to the management program and adjust fishing activities as needed.

*Conclusion*

The preferred alternative is Alternative G2, transferring all HMS fisheries to a calendar year management cycle. The calendar year would be effective for billfish fisheries on January 1, 2007 and for all species other than sharks on January 1, 2008. This alternative is preferred because it would simplify the regulatory process for constituents in the long term by managing all HMS fisheries on a calendar year, and would improve the United States' basis for negotiation at international forums. The primary concern regarding this alternative would be potential impacts to the billfish fishery when examined in combination with the potential implementation of the ICCAT 250 landings limit (Alternative E6). However, since the ICCAT 250 marlin landing limit has only been attained once in the last several years, the likelihood of any impact is low. Although economic estimates of impacts on billfish tournaments appear to be larger and of greater regional concern under preferred Alternative G2 than other alternatives, the discussion in Section 4.2.3 notes that the analysis of historical tournament data is fairly limited as an indicator of potential future impacts. The flexibility provided for implementation of a size limit increase is anticipated to mitigate impacts since the status of the fishery, and any pending tournaments, could be taken into account as appropriate. In some instances, tournaments could modify tournament rules or formats, or potentially be re-scheduled to mitigate or avoid the potential of a tournament occurring after the threshold for a management action may be reached, which could be more important to more affected regions. However, if several tournaments were rescheduled, the threshold might be reached earlier.

#### 4.3.3 Authorized Fishing Gear

As described in more detail in Chapter 2, the alternatives considered for authorized fishing gear are:

H1 Maintain current authorized gears in Atlantic HMS fisheries (No Action)

*H2 Authorize speargun fishing gear as a permissible gear type in the recreational Atlantic BAYS tuna fishery - Preferred Alternative*

H3 Authorize speargun fishing gear as a permissible gear type in the commercial tuna handgear and recreational Atlantic tuna fisheries

H4 Authorize green-stick fishing gear for the commercial harvest of Atlantic BAYS tunas

*H5 Authorize buoy gear as a permissible gear type in the commercial swordfish handgear fishery; limit vessels employing buoy gear to possessing and deploying no more than 35 floatation devices, with each individual gear having no more than two hooks or gangions attached – Preferred Alternative*

H6 Authorize buoy gear as a permissible gear type in the commercial swordfish handgear fishery; limit vessels employing buoy gear to possessing and deploying no more than 50 floatation devices, with each individual gear having no more than 15 hooks or gangions attached

*H7 Clarify the allowance of hand-held cockpit gears used at boat side for subduing HMS captured on authorized gears - Preferred Alternative*

*Ecological Impacts*

Alternative H1 would maintain the status quo for authorized gear in all Atlantic HMS fisheries. The ecological impacts of this alternative can be found in the Description of the Fisheries section of this document (see Chapter 3). Fishing effort and fishing mortality (F) would likely not increase as there would be no new authorized gears and/or participants. Bycatch and discard levels would also not likely increase because there would be no new authorized gears or changes to existing gears. This alternative is not anticipated to result in additional interactions with protected resources. However, this alternative could allow for potential increases in effort in the swordfish handgear fishery, because unlimited numbers of unattached handlines are currently allowed, and may result in additional bycatch of HMS and other bycatch species. Should such increases in effort occur, this alternative may allow for increased interactions with protected resources.

Alternative H2, a preferred alternative, would define and authorize speargun fishing gear in the recreational Atlantic BAYS tuna fishery *(i.e.*, all regulated HMS tuna species except BFT). This preferred alternative would slightly modify the alternative proposed in the Draft Consolidated HMS FMP by not allowing BFT to be fished for, landed, or retained by fishermen using speargun gear. In addition, this revised alternative would not allow the sale of any BAYS tuna harvested with speargun gear, under any circumstances, including those landed by fishermen aboard HMS CHB permitted vessels. Fishermen using speargun fishing gear would be allowed to freedive, use SCUBA, or other underwater breathing devices, and would be required to be physically in the water when they fire or discharge their speargun. Only free-swimming fish, not those restricted by fishing lines or other means, could be taken. The use of powerheads, or other explosive devices, would not be allowed to harvest or subdue BAYS tunas.

As of February 1, 2006, there were 25,238 permitted vessels participating in the HMS Angling category and 4,173 in the HMS CHB category. Based on public comment and anecdotal information, NMFS anticipates that between 50 and 1,000 individual U.S fishermen may have an interest in using speargun fishing gear to target BAYS tunas. Relative to the current number of participants in the recreational Atlantic tuna fishery, and taking into account the estimated low encounter rates for target species, the additional anticipated effort from spearfishermen would likely result in minimal negative ecological impacts on Atlantic BAYS tunas.

Under this alternative, only Atlantic BAYS tunas would be allowed to be taken by speargun fishing gear. This means that other HMS, such as Atlantic BFT, BLF, LCS, and SWO, could not be taken using speargun fishing gear. Atlantic BFT continue to be overfished and overfishing is occurring despite seven years of strict management under an international rebuilding plan with limited annual quotas. The rate of overfishing is not declining and the number of participants in the recreational HMS fishery continues to increase. Interest and activity in the small, recreational sized BFT fishery continues to grow. Since the publication of the Draft Consolidated HMS FMP in August 2005, NMFS received data on the performance of both the recreational and commercial BFT fishery, which exacerbated concerns over the ecological health and management of this stock. In the case of the commercial fishery, landings were low throughout the 2005 fishing season. The 2005 season was also marked by a noticeable lack of availability of commercial sized BFT throughout their traditional fishing range and, in particular, BFT were largely absent off southern states during the winter of 2005/2006. Although there is a high magnitude of available quota in the commercial size classes, scientists continue to be concerned over the status of this stock, especially the abundance of these larger fish that represent the potential spawners for future recruitment, particularly in the Gulf of Mexico. In the recreational fishery on smaller school size class BFT, data were available at the end of 2005 showing that, due to high landings rates in prior seasons, minimal quota would be available for a 2006 recreational school fishery. A recent publication providing a comprehensive and historical summary of BFT population dynamics, ecology, fisheries, and management concludes that the "current exploitation of BFT has many biological and economic traits that have led several fish stocks to extreme depletion in the past" (Fromentin and Powers, 2005). An international stock assessment on the current status, and future prognosis, of BFT is scheduled this year by the SCRS and new recommendations, if any, by ICCAT would not be available until November 2006. In light of the above and the uncertainty in the status and recovery of the stock, the Agency determined that the use of speargun gear for BFT is not appropriate at this time. BLF, SWO, and LCS are also considered overfished with overfishing occurring. As stock status improves and other factors change, NMFS may reconsider the use of speargun fishing gear in these fisheries, if appropriate.

The potential increase in landings for Atlantic BAYS tunas would be minimal compared with the landings by current participants and would likely result in minimal negative ecological impacts. Public comment supports the Agency's assessment that there are a limited number of additional individual fishermen expected to use this gear type. Further, public comment suggested that few spearfishermen would actually encounter the target species, and that spearfishermen could go months or years without having an opportunity to spear a BAYS tuna in the Atlantic.

In the past, there have been concerns that allowing speargun fishing gear in the Atlantic tunas fisheries could increase discards (fish speared and lost). During scoping, NMFS received comments indicating that spearfishermen often use detachable spear tips called "slip-tips," which are designed to retain speared fish, and use shooting lines, float lines, and floats that are designed to reduce fish loss. Further, the regulatory discards would likely be non-existent as spearfishermen can actively select the species and sizes of the targeted fish. Under alternative H2, NMFS does not anticipate any additional interactions with protected resources or other HMS due to the selectivity of this gear type.

Alternative H3 would authorize the use of speargun fishing gear in the recreational and commercial Atlantic tunas handgear fisheries. As stated in alternative H2 above, fishermen using speargun fishing gear would be allowed to freedive, use SCUBA, or other underwater breathing devices, and would be required to be physically in the water when they fire their speargun. Only free-swimming fish, not those restricted by fishing lines or other means, could be taken. The use of powerheads, or other explosive devices, would not be allowed to harvest or subdue tunas. Under this alternative, no HMS would be allowed to be taken by speargun fishing gear, other than Atlantic tunas. The ecological impacts of alternative H3 would likely be similar to those discussed under alternative H2 above, with the potential for some additional effort from commercial handgear tuna fishing vessels, as well as the inclusion of BFT as an allowable target species. Under this alternative, approximately 25,238 Angling, 214 Tunas Longline, 4,824 General, and 4,173 HMS CHB category vessels would be allowed to use this gear type. However, according to feedback received from HMS AP members, and because of the estimated low encounter rates, the Agency would not anticipate any substantive changes in effort or landings by the commercial handgear sector under this alternative.

Alternative H4 would define green-stick gear and authorize its use in the commercial tuna handgear fishery. This alternative was preferred in the Draft Consolidated HMS FMP but is not preferred in the Final Consolidated HMS FMP. This alternative would define green-stick under the HMS regulations and would authorize commercial tuna permit holders to sell BAYS tunas but prohibit them from possessing or retaining BFT. The definition of green-stick, and introduction of the gear to the fishery, would provide for some increase in effort. The gear is known to increase efficiency beyond that of a standard handline and rod-and-reel gear limited to two hooks per line as it would allow a green-stick line to have up to ten hooks or gangions.

Until publication of the Draft Consolidated HMS FMP, available information indicated that green-stick gear is primarily used to target YFT and other BAYS tunas. However, during public comment on the Draft Consolidated HMS FMP, considerable comment was received expressing interest in using the gear to target other species, including BFT. Green-stick gear, or variations of the gear, has been used and documented in the PLL fishery for several years. Green-stick gear catches reported in the PLL Logbook Program for 1999 – 2003 can be seen in Table 4.68. Of the 45,712 sets reported between 1999 and 2003, 54 of these sets were reported as green-stick gear. Of the 54 green-stick sets reported, 53 of those were reported from the MAB reporting area and one set was reported from the NEC. Green-stick gear was removed from the PLL Logbook Program in 2003 and has not been replaced.

On the 54 green-stick sets reported between 1999 and 2003, a total of 4 BFT, 4 BET, 678 YFT, and 54 other BAYS tunas were reported captured. Additionally, 9 swordfish, 11 pelagic sharks, and 3 LCS were also reported captured. No blue marlin, white marlin, sailfish, or spearfish were reported captured on any of these sets (Table 4.68).

**Table 4.68 Reported Atlantic Commercial Green-stick Gear Catch for 1999-2003*, in Numbers of Fish.**
Source: PLL Logbook Data

| Species | 1999 | 2000 | 2001 | 2002 | 2003* | Total |
|---|---|---|---|---|---|---|
| Swordfish | 0 | 9 | 0 | 0 | N/A | 9 |
| Bluefin tuna | 0 | 2 | 0 | 2 | N/A | 4 |
| Yellowfin tuna | 0 | 344 | 232 | 102 | N/A | 678 |
| Bigeye tuna | 0 | 2 | 2 | 0 | N/A | 4 |
| Other BAYS tunas | 0 | 26 | 28 | 0 | N/A | 54 |
| Blue marlin | 0 | 0 | 0 | 0 | N/A | 0 |

| Sailfish | 0 | 0 | 0 | 0 | N/A | 0 |
| Spearfish | 0 | 0 | 0 | 0 | N/A | 0 |
| Pelagic sharks | 0 | 1 | 8 | 2 | N/A | 11 |
| Large coastal sharks | 0 | 0 | 3 | 0 | N/A | 3 |
| Dolphin | 0 | 8 | 2 | 47 | N/A | 57 |
| Wahoo | 0 | 0 | 0 | 8 | N/A | 8 |
| Sea turtles | 0 | 0 | 0 | 0 | N/A | 0 |

* Modified logbook format eliminated green-stick gear data field.

In addition to the above data there is some anecdotal information and record of public comment on prior HMS rulemaking and HMS AP meetings regarding the pros and cons of green-stick but little substantial information. There is also no data available for sectors other than the PLL.

Due to the limited amount of data associated with the use of commercially configured green-stick gear in the Atlantic HMS fisheries, NMFS expanded its analysis to look at other available U.S. data regarding the use of commercial green-stick gear, including catch data from the U.S. Pacific (Table 4.69). NMFS is aware that the following information may not have a direct correlation to the use of commercially configured green-stick gear in the Atlantic tuna fisheries; however, to better understand the implications of authorizing this gear, NMFS took this information into consideration.

**Table 4.69 Reported U.S. Pacific Commercial Green-stick Gear Catch for 2002-2004, in Numbers of Fish and Weight in Pounds.** Source: State of Hawaii, 2006

| Species | 2002* | | 2003 | | 2004 | | Total | |
|---|---|---|---|---|---|---|---|---|
| | No. | Lb. | No | Lb. | No. | Lb. | No. | Lb. |
| Yellowfin tuna | 224 | 5,285.5 | 708 | 48,161.5 | 453 | 16,674.5 | 1385 | 70,121.50 |
| Skipjack tuna | 183 | 1,503.0 | 147 | 873.0 | 104 | 906.0 | 434 | 3,282.00 |

| Blue marlin | 0 | 0.0 | 8 | 1,217.0 | 1 | 500.0 | 9 | 1,717.00 |
| Albacore | 0 | 0.0 | 1 | 40.0 | 0 | 0.0 | 1 | 40.00 |
| Striped marlin | 0 | 0.0 | 2 | 67.0 | 0 | 0.0 | 2 | 67.00 |
| Short-nosed spearfish | 0 | 0.0 | 1 | 20.0 | 0 | 0.0 | 1 | 20.00 |
| Bigeye tuna | 0 | 0.0 | 12 | 184.0 | 2 | 24.0 | 14 | 208.00 |
| Misc. tuna | 0 | 0.0 | 4 | 60.0 | 1 | 129.0 | 5 | 189.00 |
| Mako | 0 | 0.0 | 1 | 70.0 | 0 | 0.0 | 1 | 70.00 |
| Black skipjack | 0 | 0.0 | 0 | 0.0 | 1 | 20.0 | 1 | 20.00 |
| TOTAL | 428 | 7,122.0 | 923 | 51,332.5 | 569 | 18,405.5 | 1920 | 76,860.00 |

* October - December only

The amount of effort deployed in the U.S. Pacific commercial green-stick fishery to harvest the catches above is as follows: Calendar Year (CY) 2002 (Oct – Dec only), eight licensees conducted 59 total trips (367.0 hrs), of which 34 were at fish aggregation devices (FADs) (176.0 hours). Six of the total trips were "did not catch" trips. In CY 2003, 19 licensees conducted 188 total trips (1,504.0 hours), of which 35 were at FADs (258.0 hours). Sixteen of the total trips were "did not catch" trips. In CY 2004, 19 licensees conducted 116 total trips (801.5 hours), of which 24 were at FADs (151.5 hours). Twenty of the total trips were "did not catch" trips (Table 4.69).

Data from the Pacific Ocean show that, in addition to tunas, dolphin, and wahoo, the Pacific green-stick fishery has interacted with blue marlin, striped marlin, and short-nosed spearfish (Table 4.69). This indicates that, although no billfish have been reported captured on green-stick gear in the Atlantic commercial HMS fisheries in recent years, interactions with Atlantic blue marlin, white marlin, sailfish, and spearfish could be possible under this alternative. Public comment and historical logbook data illustrate that this gear type has been used in the HMS fisheries for several years and classified by fishermen as either longline or handgear. What is less clear is whether in fact the green-stick gear was configured in conformance with the regulations appropriate to the HMS regulatory vessel permit regime and definition of longline and handgear, (*e.g.*, number hooks, type of hooks, etc.). Also, since these data were collected, regulatory circumstances have changed regarding longline gear. Vessels with pelagic longline gear onboard are now required to use specific circle hooks rather than previously used J hooks, and as the fishing performance of these two hook types varies considerably, it is not possible to project future effectiveness of green-stick gear equipped with circle hooks based on past data when the gear was deployed with J hooks. During the public comment period, numerous comments were received expressing confusion over the current regulatory regime, unease over the potential impacts and intent of the preferred alternative in the Draft Consolidated HMS FMP, and concern over potential negative impacts of the green-stick gear.
